COAL AGE

With which is Consolidated The Colliery Engineer

DEVOTED TO COAL MINING AND COKE MANUFACTURE

ISSUED WEEKLY

VOLUME XIV

July 1 to December 31, 1918

McGRAW-HILL COMPANY, INC.
10TH AVE. AT 36TH ST.
NEW YORK

COAL AGE

With Which is Consolidated
The Colliery Engineer

INDEX TO VOLUME XIV

July 1 to December 31, 1918

EXPLANATORY NOTE

Note—Illustrated articles are denoted by an asterisk (*), book notices by a dagger (†). Titles are often abbreviated. They are indexed under their most important words, or, if no word be distinctive, under their first one (except "A," "The," etc.), or under some topical word not found in the title. Authors', geographical and other proper names are also used freely.

Following is a list of the pages included in the several numbers of the volume, by date:

July 6	Pages	1– 46
July 13	"	47– 90
July 20	"	91– 154
July 27	"	155– 200
Aug. 1	"	201– 248
Aug. 8	"	249– 296
Aug. 15	"	297– 340
Aug. 22	"	341– 384
Aug. 29	"	385– 426
Sept. 5	"	427– 476
Sept. 12	"	477– 532
Sept. 19	"	533– 578
Sept. 26	"	579– 624
Oct. 3	"	625– 672
Oct. 10	"	673– 720
Oct. 17	"	721– 766
Oct. 24	"	767– 806
Oct. 31	"	807– 845
Nov. 7	"	846– 888
Nov. 14	"	889– 928
Nov. 21	"	929– 970
Nov. 28	"	971–1014
Dec. 5	"	1015–1058
Dec. 12	"	1059–1102
Dec. 19	"	1103–1146
Dec. 26	"	1147–1188

COAL AGE

Volume 14 New York, July 6, 1918 Number 1

Jo Brown's Opinion

How to appreciate the other man's *point of view*

What we are going to tell about here is happening daily at nearly all mine operations, with this exception: too few managers are as wise in their understanding of human nature as the one in this story

PAYDAY afternoon at a Southern coal mine. Most of the miners negroes; carefree in disposition, but quick to sense the attitude of employer or clerk as friendly, unfriendly or neutral. As each man received his pay statement, he stepped aside and began—in most cases laboriously—the mental effort of balancing the amount due with his recollection of earnings and stoppages. Most accomplished this to their satisfaction, for the company had the reputation of being careful in its payroll affairs. These joined the long line in front of the paymaster's window. A number, however, could not verify the statements to their satisfaction. These returned to the adjustment window with such remarks as:

"Cap'en, my time's wrong; yo' sho' is done stopped too much on me."

"Boss, I'se in a headin'; yo' ain't got all my coal on dis statement."

JO BROWN was one of these. The clerk verified his statement with the payroll and found it right. He handed it back to Jo, saying, "Go get your money, nigger—that's right." But Jo was not satisfied. Not only did he dislike being called "nigger" so abruptly, but he had forgotten a cash advance of $5; and the clerk, knowing his roll to be right, could not see that Jo had any kick coming. So again he told him to stand out of the way. But Jo didn't get out of the way. He stood there studying his statement, a black picture of sullen grief, trying now and then to address the clerk again but receiving no attention.

Right here my manager friend, who had me in tow, arrived.

"What's the trouble, Jo?" he asked.

"A whole lot, Mr. Jones. I'se short-changed $5."

"Let's see your statement," said my friend. "Dan," he called to the clerk inside, "let's see the order Jo signed for this cash advance."

The clerk soon produced it, and the manager showed it to Jo and asked if he didn't remember getting it.

"Yes, sir, I 'members it now," said Jo; "but dat man just told me his payroll was right, and he ain't never showed me nuthin'."

"Well, you be in the hole Monday and make that $5 back," said my friend.

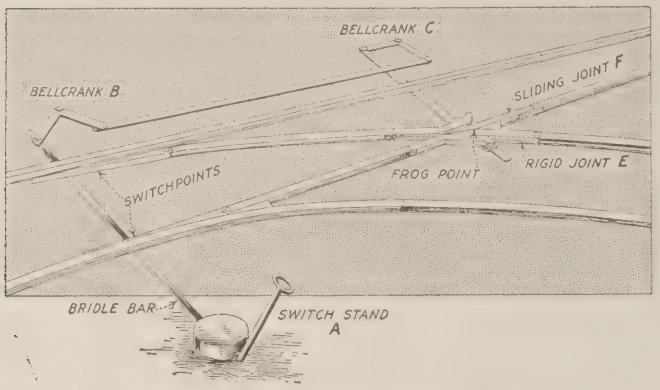
"Yes, sir, I sho' will," smiled Jo as he made for the paymaster.

"You're a good trouble adjuster," I said to my manager friend as we walked away.

"No," he replied, "it isn't that. I'm no better than Dan or any other mine clerk could be if they would only learn something I learned a good many years ago, and what, I fancy, a good many men fail to see."

"What's that?" I asked.

"Simply this: *It's the easiest thing in the world for every one else to feel that Jo Brown can't have a complaint that amounts to much; but Jo Brown can't understand why everybody else in the world can't see that his complaint is the biggest thing on the map.*



"And in this, Jo Brown is only human. I find I like my own opinions best. Don't you? So whenever I find a Jo Brown I first consider his viewpoint and adjust his troubles from that angle. He thinks I'm a wonder simply because I'm an exception and therefore something new to him, and his troubles are soon over."

I left my manager friend that day with his treatment of Jo Brown uppermost in my mind. I wish I could pass his viewpoint of individual troubles to every mine manager in the business; for don't you think it would pay if all of us—miners and managers—could learn to appreciate Jo Brown's point of view?

IDEAS AND SUGGESTIONS

Movable-Point Frog

At those mines and collieries where loose wheels are used on the mine cars, difficulty is sometimes experienced through the wheels climbing the frog at switches and derailing the car or trip. In such cases a guard rail at the frog is not always effective, since the loose wheels

DETAILS OF A MOVABLE-POINT FROG

sometimes have considerable play on the axles. To overcome this an auxiliary frog point is sometimes used. This may be placed either side up and on either side of the fixed-frog point to suit the throw of the switch

VIEW OF A MOVABLE POINT FROG INSTALLATION

points, and when so placed completely fills the space between the frog point and the adjacent rail.

To obviate this difficulty, George Thomas, outside superintendent at the Plymouth No. 5 breaker of the Delaware and Hudson Coal Co., has devised and installed a type of switch wherein the point of the frog moves from side to side in conjunction with the switch points. This frog needs no guard rail.

As may be seen in the accompanying drawing, this switch is not materially different from the ordinary type. Motion is transmitted from the ordinary switch stand *A* through a suitable elongated bridle bar to the bell crank *B;* thence through an adjustible tubular rod to the bell crank *C* and thence to the frog point *D*. The frog point is pivoted at *E*, while the opposite prong of the point is free to slide sufficiently at *F* in the fishplates attaching it to the rail to allow the point to move from side to side.

This switch has been in operation for some time and thus far has given entire satisfaction. It is not complicated and can be built at any ordinary mine shop.

Now Is the Time for Repairs

By N. H. Seaburg
Boston, Mass.

The public is being advised by the Fuel Administration to stock during the summer months as much coal as it can in order to insure against a repetition of last year's fuel famine. Although it is a well-known fact that the mines are not producing the necessary amount of coal that the current year demands, there is another feature of the problem that is being somewhat slighted, probably for the reason that there seems no immediate solution for it. This is transportation, a factor which is equally important with the mining of coal, in that no matter how much coal is produced it is of no value to the distant consumer unless it can be delivered to him.

The country depends upon the railroads to move the coal that is mined, either to tidewater or other destination, and as it is hoped this tonnage will be increased over last year's, it is evident that the railroads have been assigned a tremendous task. Taxed as they were the past winter to move that season's tonnage, they are nevertheless expected to move much more this year, with practically no addition to rolling stock or even repairs to present equipment.

The strain put upon the coal-carrying equipment last winter was unusually severe, and there has been no letup since then to allow of making the necessary repairs, except when there has been an actual breakdown. This, of course, is bad policy, and amounts to the avoidance of a temporary halt in the transportation of coal through inviting a serious tie-up, when there must come a general car and locomotive shortage. Our present course of action is plunging us headlong into such a contingency and it is folly to delude ourselves into the belief that we can tax our present rolling stock as we are doing without incurring disaster.

It is indeed time to call in the doctor. Looking after the present without thought of the future should not be the attitude of the Fuel Administration. Its desire to have the public stock up during the summer months is excellent, but to do so at the expense of the Nation's

transportation system is questionable expediency. The interdependence of production and distribution is so great that the breakdown of the one means the breakdown of the other. There is little wisdom in crippling, perhaps beyond repair, the entire rolling stock of the railroads in order to stock up coal during the next few months of the year. The trifling gain to be achieved thereby would be more than offset by the injury to the cars and locomotives this effort would possibly cause.

In order to secure the greatest efficiency from the present equipment, which is highly essential on account of the difficulty in obtaining new material, it would seem a matter of prudence to repair and overhaul immediately every defective car and locomotive in the Nation's transportation system, even though this may seriously hamper the movement of freight for a month or more. Cars and locomotives cannot be expected to last forever without attention. If repairs are neglected, there is only one alternative—the scrap heap.

Shall we wait until our equipment is ready to be scrapped before making repairs? Then, indeed, we are rushing headlong into a danger which cannot be adequately pictured. Let us not wait and call in the doctor when it is too late. Let us rather awake to our danger and take the necessary steps to remedy our ills, so that the doctor will not be required.

Of course, this will entail some inconvenience, but this is far preferable to attending a funeral. Optimism, beguiled by a false sense of patriotism, should not blind us to the great difficulties ahead which must be overcome.

Saving Materials—A Way to Victory

By NEILL HUTCHINGS
Mobile, Ala.

THIS is a war of resources. Germany will be defeated with materials. Coal, iron, steel and allied products will turn the scale of victory in our favor. Every business in America must come to realize that it can only be patriotic by using materials carefully. It is the same with the individual. In fact, "slackers" are already of two kinds: the person who won't fight and the person who won't give up the use of luxuries.

The demand for materials for war purposes is almost past all comprehension. The appetite of war for materials is voracious. If, as the editor of *Coal Age* recently set forth in an article on "War as an Industry" in the *Saturday Evening Post*, it required 9,000,000 tons of coal to produce and transport the million and a half tons of shells used at Verdun in a six-months' period, how can any patriotic coal miner or mine management fail to visualize the task ahead of the coal industry! It is no secret that the Government needs for steel for war purposes will consume the entire make of steel in this country. Neither is it a secret that it takes iron ore and coal to make steel. Every barrage fire laid down on the German lines in France has in it some of the coal mined by the very miner who reads these words.

Finally, the war will be carried into Germany. There will never be a stopping point this side of the Rhine once the scene is reversed and the Allies are pushing the Germans back. But the Rhine will never be crossed on German-made bridges. The materials for that crossing will come in large measure from the mines and mills of America. The road to Berlin must be paved with millions of tons of materials produced and saved in America for this job.

There's the real point. If everybody were permitted to use materials as they have been accustomed to, there might not be enough to pave that road to Berlin. So we have got to save as well as produce. Are you, Mr. Business Man of America, Mr. Mine Manager and Superintendent, using materials with an eye to the needs of your sons and comrades in France? Have you eliminated all the wasteful practices in your business since the war started in order there would be more oil, coal, foodstuffs, etc., for the man in France? Do you still grease your mine cars so that your tipple is caked with oil and ready to burn at the touch of a match, which means wasting the material it would take to replace it? Are you permitting rockfalls to bury good mine timbers, rails, ties, etc., when the right practice would avoid them. You say you are not—but are you sure? It's up to you to know.

Do you—whether you are the miner or the manager—do a lot of things without regard to the needs of your country for materials? If you do, you are getting dangerously close to "slacker" ground. In fact, the individual or the company that hasn't yet come to know that what one man wastes counts big in the present scheme of things is nothing short of a slacker.

Remember: If it takes a small forest to build a wooden ship, or the output of a good-sized mine for a month to build a steel vessel, can you fail to see what slack production or leaks in the use of material means?

Don't forget, too, you can waste material by simply being careless about it. Fire, breakage, improper handling and all the rest mean wasted material. There ought to be a fire inspector on top of every job of any size in this country right now, and an expert to show green men how to handle and use materials properly. Nothing should be wasted that might be saved. If you are a wise manager and a patriotic man, you will make a trip of inspection yourself to see that nothing in the way of materials is wasted and that everything that is humanly possible is done to increase your output.

Above all, keep in mind the road to victory. Remember it must be built of materials we make and save at home. Shall a single boy die in France because his countrymen—whether coal miners, mine managers or what-not—failed to make or save the material that would have saved him?

Let's pave the road to victory with the materials we can save from waste. Can any honest American want to do less? Let's carry on with the war by saving materials.

FIG. 1. NO. 6 PLANT OF THE MADISON COAL CORPORATION AT DIVERNON, ILLINOIS

Model Safety-First Coal Mine in Central Illinois

THE president of the Madison Coal Corporation of Illinois, A. J. Moorshead, has made a most careful analysis of the dangers attending those engaged in the mining and handling of coal preparatory to shipment. He also ascertained the percentage of the accidents in each class to the total number of accidents. This interesting information produced results, as it incited the official in question to action looking to the practical betterment of conditions in and around the mines of his company. Among others the No. 6 mine of the Madison Coal Corporation is literally bristling with safety devices—it is nearly as foolproof a plant as is met with in the coal fields.

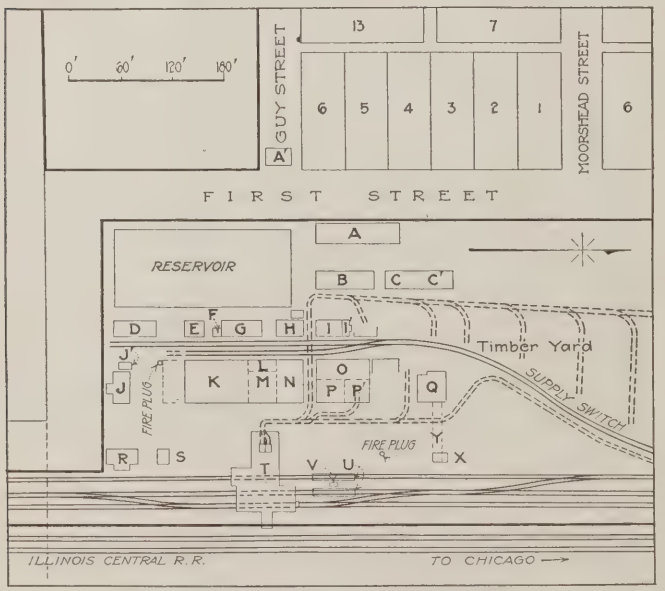


FIG. 2. PLAT OF SURFACE FEATURES OF NO. 6 PLANT OF MADISON COAL CORPORATION

The following buildings are noted: A, Washhouse; B, Lumber Warehouse; C, Cap-piece house; C^1, Masonry storehouse; D, Forage house; E, Oilhouse; F, Supply clerk's office; G, Supply house; H, Coke house; I, Lumber supply; I^1, Bosses' washhouse; J, Office; J^1, Wagon scale; K, Boiler house; L, Pump room; M, Hoisting-engine room; N, Generator room; O, Machine shop; P and P^1, Blacksmith shop; Q, Fan; R, Rescue station; S, Haulage-engine house; T, Tipple; U, Scales; V, Scale house; Y, Tunnel fan to air shaft; X, Air shaft.

Mine No. 6 of the Madison Coal Corporation is on the outskirts of the town of Divernon, Ill. It is in the Springfield district of Sangamon County, on the line of the Illinois Central R.R. In going about the plant and the town adjacent one is impressed with the neat and orderly appearance of the premises. This is in line with all well-regulated business; waste is avoided, workmen are apt to be more careful and efficient, and the appearance of a plant certainly counts for something—generally in dollars and cents.

A general view of the surface plant of the operation in question is shown in Fig. 1. A detail plat of mine and yard buildings is given in Fig. 2; the material of each building is concrete, brick or steel—fireproof construction throughout being employed in the main. The north side of the tipple is shown in Fig. 3 and the south view in Fig. 4. In Fig. 5 the longitudinal elevation of the tipple is given, on which are located the chutes, screens and other coal-handling machinery. The tipple steelwork was erected some time ago (in 1900) by the Kenwood Bridge Co., of Chicago, Ill. A straight three-track screening outfit was installed. A self-dumping cage, made by the Dunkin Foundry and Machine Co., of Alton, Ill., dumps the run-of-mine coal into a

weigh basket, or hopper, from which it goes to the shaking screens. Ordinarily, run-of-mine coal is shipped from this mine; but six sizes can be made with the combination of the shakers and the circular screen. The latter screen is over the bin shown at the south side of the tipple in Fig. 4. Near the dump an opening can be utilized in the main screen when wagon and boiler coal are desired. The wagon dump is shown at the base of the bin in Fig. 4, and the screenings from this dump go to the boilers. In the scale room at the tipple coal is weighed as each car is dumped, and coal is weighed again when loaded on railroad cars for shipment. These scales were made by the St. Louis Scale Co., of St. Louis, Mo. The Illinois Central R.R. uses run-of-mine coal from this plant and sometimes screenings are taken out for a pumping station in connection with the plant. If coal is to be re-screened it is elevated and run through the circular screen which makes the smaller sizes—1¼ in. down.

FIG. 3. NORTH VIEW OF NO. 6 TIPPLE AT DIVERNON

On the plat of the surface features, Fig. 2, is shown a reservoir which has been found entirely inadequate for the requirements of dry spells. Its capacity does not permit of the storage of sufficient water to carry the plant over seasons of drought. A large, new reservoir is being made just west of the old one to hold 12,000,000 gal. of water, at a depth of 11 to 12 ft. The creek nearby will supply water for the new reservoir, which will be filled and kept as a reserve supply.

West of the tipple is the boiler, engine and generator house. Steam is generated in eight 72-in. by 22-ft. boilers; six of these were furnished by Rhone & Sons, of St. Louis, Mo., and two by the Brownell Boiler Co., of Dayton, Ohio. The boilers are hand-fired. The 26 x 36-in. first-motion hoisting engine was made by the Litchfield Foundry and Machine Co., of Litchfield, Ill. The hoisting rope is 1⅜-in. steel and is stowed on two 8-ft. drums. The engine is equipped with a steam brake and steam reverse; also a Nicholson engine stop, manufactured by the Vulcan Iron Works, of Wilkes-Barre, Pennsylvania.

In connection with hoisting, mention should be made of the "humble hooks," an English device, of which the Macomber & White Rope Co., Kenosha, Wis., is the American agent. These hooks are locally termed "Johnny Bulls." One is kept as a reserve, and there has not been an overwind with serious consequences since they have been installed. However, the cage has been hung up several times, on which occasions the only practical damage done was a hole in the tipple roof, made by the end of the hoisting rope when it pulled over the sheave. The hooks consist of heavy steel plates and the device is about 2 ft. long and 8 in. or so wide. It is the connection between the rope socket and the cage chains, to which it is attached, by clevises. In case of an overwind, the humble hooks pass through a hole in a 1¼-in. horizontal steel plate; just enough clearance is allowed to pass the upper end of the hook; at the lower end a lug projects out at each side. The lugs are pivoted, so that as the lower ends are forced in by the plate the upper ends fly out, releasing the rope socket clevis. As the cage drops, the upper ends of the lugs settle on the horizontal plate and stop further downward movement of the cage. Back of the engine room are two 12 x 8 x 12-in. steam pumps made by the Hooker Steam Pump Co., of St.

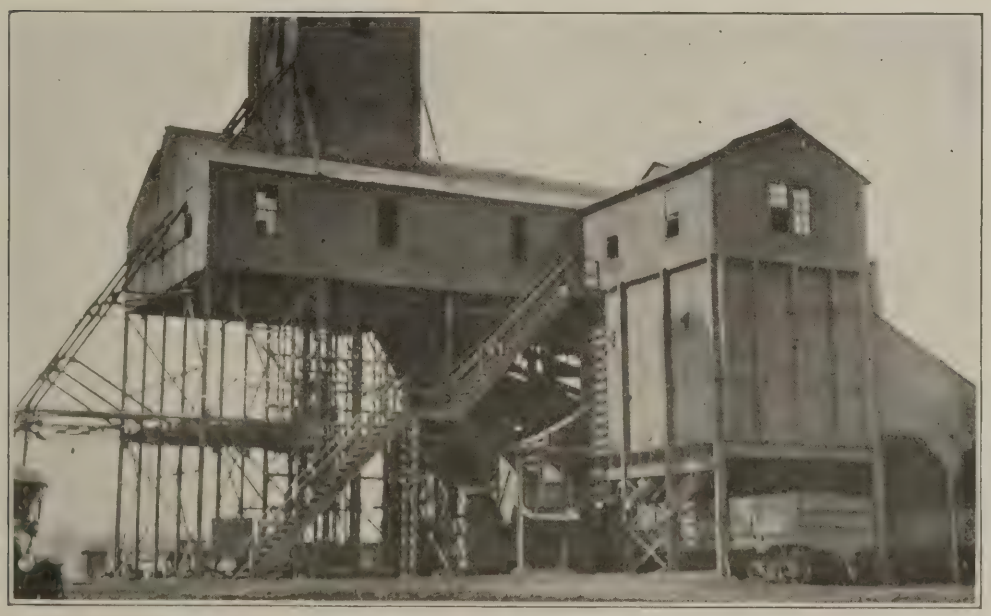

FIG. 4. SOUTH VIEW OF NO. 6 TIPPLE AT DIVERNON

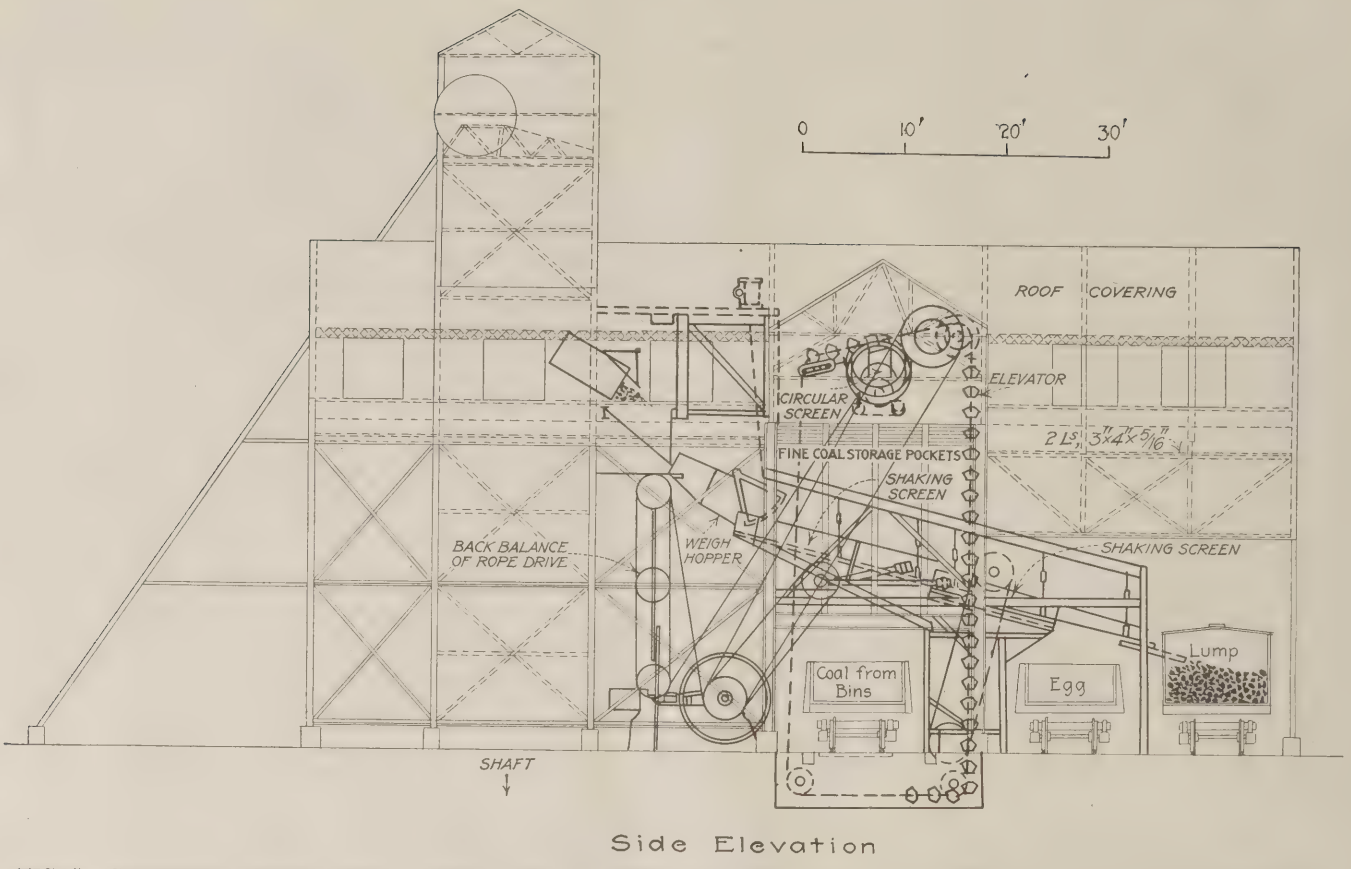

FIG. 5. SIDE ELEVATION OF NO. 6 TIPPLE OF MADISON COAL CORPORATION, SHOWING LOCATION OF MACHINERY

Louis, Mo. In this room there is also a Cochrane feed-water heater and purifier, made by the Harrison Safety Boiler Works, Philadelphia, Penn. One pump forces cold water into the heater and the other pumps from the heater to the boilers.

Adjoining the engine room on the north is the generator room, in which are three electrical units for furnishing current for power and lights. There is one 100-kw., 250-volt Western Electric Co. generator, one 175-kw., 250-volt General Electric Co. generator and one 100-kw., 220-volt General Electric Co. generator. All are direct-current machines and run by Skinner automatic engines. There is a four-panel switchboard in this room, one panel for each generator, and the fourth panel for the main circuit breaker and the switch for the main line down the shaft.

The machine shop at this plant handles all repair work at the mine, and some other jobs, such as making a lathe for turning wheels and a drill press for the local mine shop. The shop is equipped with a large lathe from J. W. Wright & Co., St. Louis, Mo., and one of medium size made by the Springfield Foundry Co.; a planer from W. C. Johnson & Sons Machinery Co., St. Louis, Mo., a radial drill, Niles Tool Works, Hamilton, Ohio, shear and punch, by New Doly Manufacturing Co., Jeanesville, Wis., shaper, from Smith & Mills Co., Cincinnati, Ohio, and a pipe die machine from Curtis & Curtis, Bridgeport, Conn. A pipe-threading and bolt-cutting machine has been ordered. At the forge in the blacksmith shop adjoining are three steam hammers which are useful in repointing bits for mining machines, among other purposes. A Jeffrey centrifugal 5 x 16-ft. fan ventilates the mine; it is run by a 22 x 24-in. engine made by the Ridgway Dynamo and Engine Co., of Ridgway, Penn. It is run at a normal speed of 90 r.p.m. The fan can be reversed and run exhaust if desired. In the haulage engine house near the tipple is the mechanism for operating the rope system which parallels the empty and loaded railroad tracks

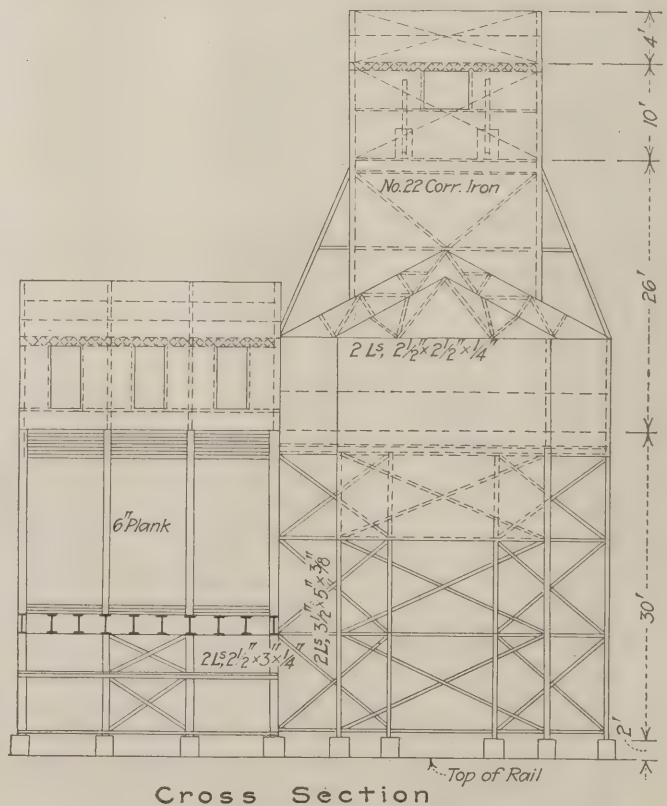

FIG. 5A. CROSS-SECTION OF NO. 6 TIPPLE

and which moves the empty and loaded railroad cars. Each end of the ¾-in. rope is attached to two drums respectively, which are driven by one shaft through friction. There are links on the haulage rope every 250 ft. which permit connection with cars by a short rope. The system is reversible; as the rope winds up on one drum it feeds out from the other.

The employees and their families are well taken care of by the Madison Coal Corporation, which believes that they should have homes and not shacks. A new town adjacent to the plant contains 100 houses which were built by the company at a cost of $1500 each, including a summer kitchen, outbuildings, fences, cistern and other improvements which add to the attractiveness of the town and act as an incentive to the men to keep their places in good shape. The camp at Glen Carbon, another plant of this company, is 30 years old, but the same conditions prevail as to neatness and order. The houses are kept in good repair, attractively painted, and probably are highly appreciated by their occupants.

The mine town at Divernon avoids monotony by having four different types of houses, no two of the same style being adjacent. This feature and the variety in the colors of the paint used on them lend attractiveness to the village. The houses are arranged in four rows, one of which is shown in Fig. 7. Note the neat division fences, the absence of a front fence, the row of shade trees along the street, other trees in the yards and the lawns at each home. Such a scene would do credit to some city suburbs. When the trees fill out in the yards, the village will be still more attractive.

All are four-room houses of the bungalow style and of the dimension and general arrangement shown in Fig. 6. The inside details are about the same for all four types. In the rear of each house is a 10 x 14-ft. summer kitchen and a cistern 6 ft. in diameter and 8 ft. deep. Each house has a lot 150 ft. deep by 50 ft. in width with a 20-ft. lawn in front. Running water is brought close to each house at the division fence, every other side fence having a hydrant which supplies the house on either side. The house occupied by J. H. Miller, the mine manager, is shown in Fig. 8. It is a commodious six-room dwelling 1½ stories in height. A large boarding house which accommodates 40 men has also been built by the company.

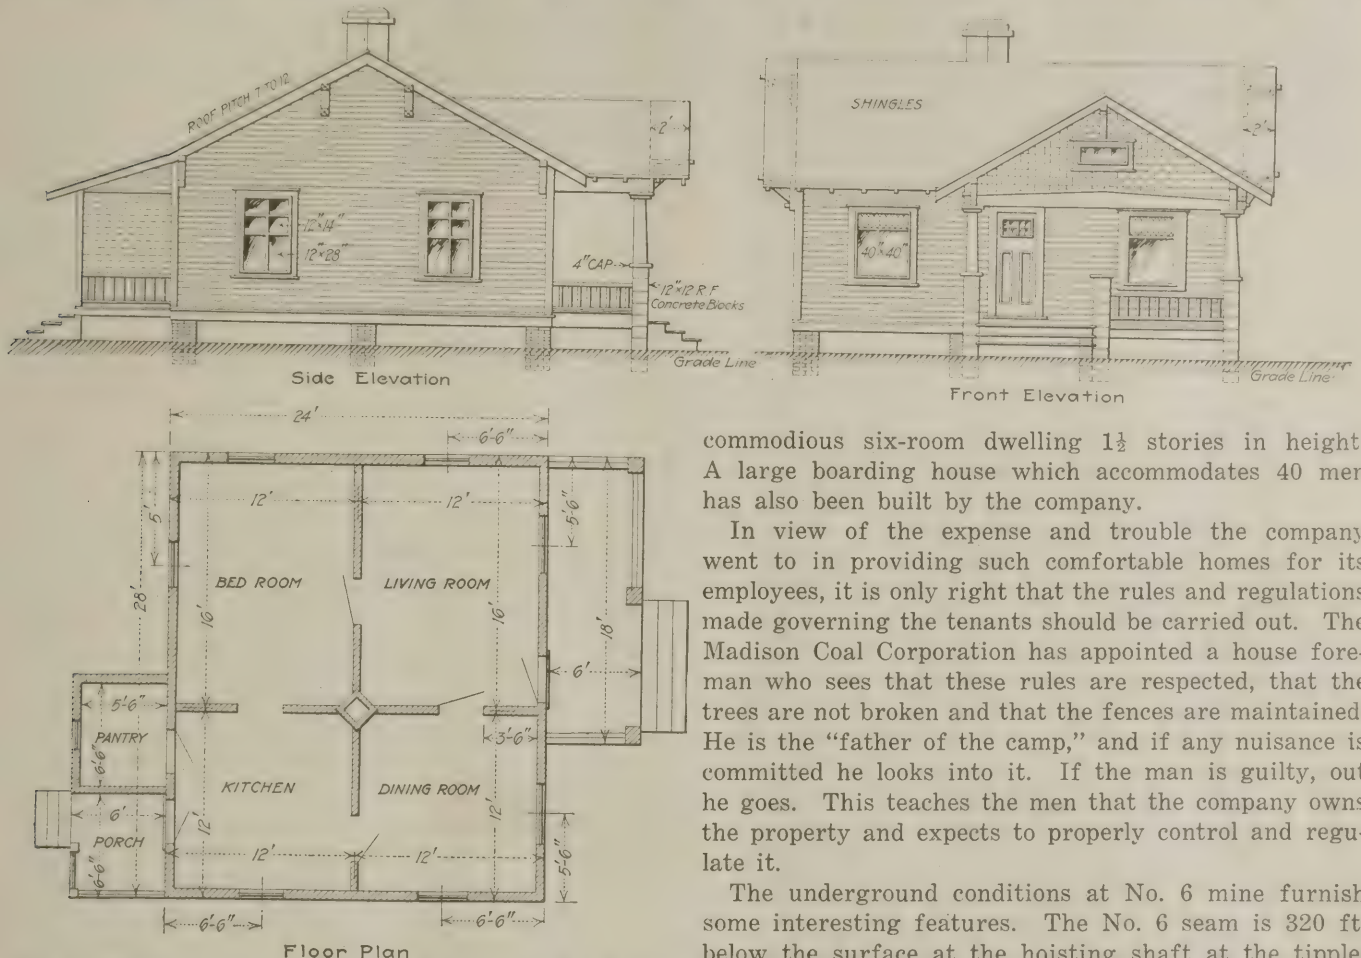

FIG. 6. ELEVATIONS AND PLAN OF ONE TYPE OF EMPLOYEES' HOUSES OF MADISON COAL CORPORATION'S NO. 6 PLANT

In view of the expense and trouble the company went to in providing such comfortable homes for its employees, it is only right that the rules and regulations made governing the tenants should be carried out. The Madison Coal Corporation has appointed a house foreman who sees that these rules are respected, that the trees are not broken and that the fences are maintained. He is the "father of the camp," and if any nuisance is committed he looks into it. If the man is guilty, out he goes. This teaches the men that the company owns the property and expects to properly control and regulate it.

The underground conditions at No. 6 mine furnish some interesting features. The No. 6 seam is 320 ft. below the surface at the hoisting shaft at the tipple, and averages 8 ft. in thickness. This is the bed which produces the greatest tonnage and is the one worked all through the central and southern coal-mining portions of Illinois. The method of mining employed here is the room-and-pillar combined with the panel system. The impurities in the seam include a blue band 2½ ft. from the bottom which runs about 1 in. in thickness. Sulphur bands and balls are also found throughout the coal. The top is generally a clod and black slate occurring from nothing to 8 ft. in thickness. It is full of seams. Above the slate is a solid limestone.

The slate weathers badly at certain times of the year and it is the custom here wherever practicable to leave up about 1 ft. of top coal as protection against this spalling of the top. Props are set with a coal top and crossbars are placed where the coal comes down, especially on entries. On haulageways, if the clod is not more than 2 ft. thick, it is taken down to the inside parting and the entry is timbered from here to the face. At

FIG. 7. EMPLOYEES HOUSES AT DIVERNON

this mine one prop is used for every 10 to 12 tons of coal mined.

No pillars are drawn and rooms are turned off on 60-ft. centers—30-ft. room and 30-ft. pillar. A barrier pillar of 20 ft. is left between the ends of rooms, and there is an entry barrier of 75 to 100 ft. At present one pair of main entries is being driven and eight pair of cross-entries. From the cross-entries, stub entries are driven of an average width of 15 ft.; the main and cross-entries are each about 12 ft. wide. The entries are run on centers, and the assistant mine manager runs the rooms with a compass. Two surveys of the workings are made during the year.

The method of mining employed at the No. 6 mine, in the main, is the one in vogue at a large number of Illinois operations. No attempt is made to extract more coal than can safely be removed without causing subsidence of surface. Also, all coal is taken out on the advance; when all the rooms in a panel are worked to the required distance, then the panel is finished. While it is expected that pillars have been correctly proportioned to opening, and will not fail in the service for which they were left, nevertheless the wisdom of the panel system has been abundantly justified in Illinois. In many instances barrier pillars have limited squeezes to the panel in which the trouble started. A force fan furnishing 130,000 cu.ft. of air per minute ventilates the mine, in which there are eight splits. The overcasts are of concrete and the stoppings are made of slate and old ties plastered with cement and sand. Three mine examiners cover the workings. They find gas occasionally, and the miners stay out of the places in question until the face bosses either brush out the gas or put up a curtain to deflect the air current which removes it. The main or hoisting shaft has two compartments. The air shaft is equipped with a stairway which is partitioned off from the portion used for ventilation. At the bottom of the main shaft is an automatic deflector arranged to be operated by the cage; this device tends to throw coal falling down the shaft away from the bottom men. As the cage approaches the landing, it engages a pawl and moves the deflector into position. Automatic caging devices are installed on the loaded tracks at the shaft bottom. Within a few hundred feet of the bottom of the shaft are a number of interesting features. Between the main and air shafts is an underground room fitted up as a rescue station to give first aid; in it is a first-aid cabinet. In the rear is a small room which is kept hot for special cases requiring such treatment. Nearby, at the air shaft, is a 35-hp. pump of General Electric Co. manufacture; it is figured for a head of 600 feet.

The main entries run east and west from the main shaft, and the tracks are graded so that the loaded cars run to the shaft and the empty ones away from it. At a short distance from the shaft, on the east side, one track is considerably lower than the other one paralleling it. As a safety precaution a pipe hand rail is in position between the two tracks, suspended from the top by brackets. Concrete has not been spared where needed on entries, traveling ways and rooms around and near the hoisting-shaft bottom. Conveniently accessible to the shaft is a waiting room for miners. Seats have been placed on both sides of a traveling way, the sides of which have concrete walls. Whitewash and electric lights contribute to the cheerfulness of the place.

FIG. 8. TYPE OF HOUSE OCCUPIED BY MINE MANAGER

Close to the shaft, also, are accommodations for the motive power for handling cars. A motor barn, with a 2-in. plank floor, has 16 separate switches so that any motor can be taken out without interfering with any other. The main haulage is done by five motors—one 15-ton Morgan Gardner, two 15-ton Jeffrey and two 12-ton Goodman locomotives. Main haulage includes four hauls of about 7000 ft. and five hauls of about 5000 ft. The 15-ton locomotives haul 25 to 30 car trips and prevented from getting together at the bottom. Mechanical gathering is done by four 5½-ton General Electric storage-battery locomotives; the Exide storage batteries used in these locomotives were made by the Electric Storage Battery Co., of Philadelphia, Penn. Additional gathering motors have been ordered.

About 40 mules assist in gathering cars at present, but these "hay burners" will be supplanted by storage-battery motors eventually. Considerable thought was

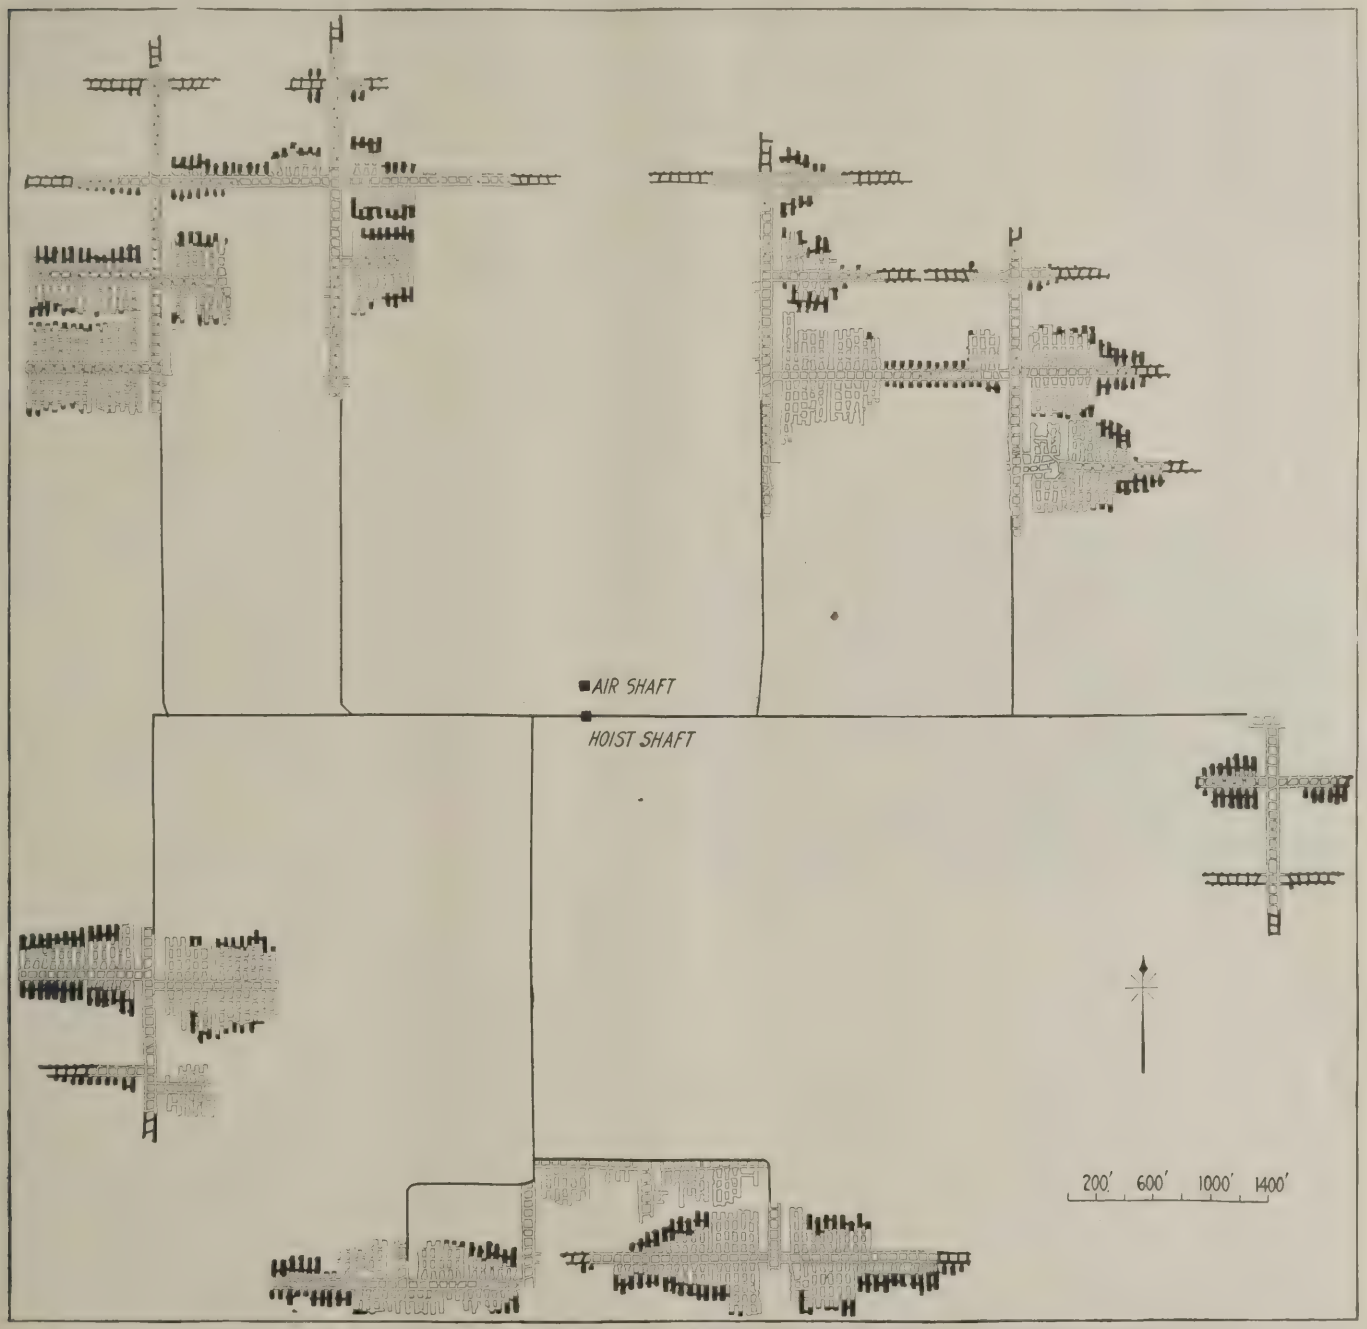

FIG. 9. MAP OF ACTIVE PORTIONS OF NO. 6 MINE OF MADISON COAL CORPORATION

Intermediate territory between the shafts and active portions worked out. The heavy lines leading from the hoist shaft to the active portions of the mine are main haulage roads; main partings are at ends of main haulage roads. Heavy black portions of workings show the last extensions made to mine map on May 5, 1918

the 12-ton motors 20 to 25 cars at a time. There are nine active partings altogether. On the mine map (Fig. 9) the parting is at the end of the main haulage in each case; the main haulage lines are indicated by heavy lines. All partings are lighted by electricity and also haulageways where mules work. On main-entry haulageways, where two or more motors travel, they are protected by a block signal system—also motors are thus given in planning the stable for the mules. Concrete floors, side walls, partitions and mangers are not only of substantial construction but fireproof as well. A sheet-iron feed box is fitted into each manger. The concrete partitions extend from the floor to the level of the top of the manger; above this level the partition consists of iron pipes. An automatic spray system runs the length of the stable both at the back and front of the stalls.

On the opposite side of the shaft from the motor barn is the machine shop; it is a room 18 x 120 ft. in dimension. It is equipped with two overhead cranes with a 2½-ton block. Motors and mining machines are repaired here, armatures wound, etc. The shop is about 375 ft. west of the main shaft.

Nineteen Goodman breast mining machines are available for undercutting at this mine; 14 machines are kept steadily at work, which gives ample opportunity for any necessary attention to the idle machines. The machines undercut to a depth of 7 ft. and 42 in. wide. A double shift is worked on undercutting and 25 cuts are made per shift by each machine, or an average of 2½ rooms. Bits generally have to be set every one to ten runs, but they have been changed four times in one run when the sulphur was particularly bad. The miners, or "loaders" as they are termed in this case, blow the coal and load it.

As this mine is dry and dusty, the water system covering the territory at and adjacent to the main shaft is an important safety precaution. A 2-in. water pipe with hose connections every 40 ft. connects with a water

FIG. 10. MINE RESCUE STATION

supply on the surface. A water car regularly sprinkles the main roads on Sundays, and the surplus work of this kind is done at night.

In order to know definitely who enter the mine and whether they leave it again, the following system has been adopted by the Madison Coal Corporation. Before a man goes down the shaft in the morning he leaves a "life check" with the man at the surface cage landing. When all the men have gone down, the checks are sent down and hung up on a board at the end of the miners' waiting room. The inside men get their checks at night and hand them in to the proper party at the bottom cage landing before they go out. If a daily record is kept of those going into and coming out of the mine, it may be valuable evidence on occasion. In some instances, in event of explosions or other mine disasters, it is desirable to have such information correct and quickly available. In normal times it might be a satisfactory arrangement to keep track of individual workers.

An automatic safety-gate device is installed at the main-shaft surface landing. It includes a lock at the gate operated magnetically; also, wires lead from the lock to contacts on the hoisting engine shaft, so arranged that the lock is only released when the cage is at the landing. Two red electric-light bulbs are mounted on the front wall of the engine room in plain sight of the engineer. These flash when the gates are raised at the landing. The engineer can release the lock at any time by a special switch.

Coming out of the mine at night the miners and other inside men resort to the wash-house before going to their homes. The No. 6 wash-house has 572 lockers in all and 30 sprays or showers. At present there are 650 employees at this plant, of which number 602 are inside men and 48 are on top. The various bosses have a separate wash-house with 18 lockers.

The mine is fortunate in having a rescue station on the ground; it is built of cement blocks and is shown in Fig. 10. The large main room in the center is utilized for first-aid work. The injured man is brought here for immediate treatment and the doctor is summoned. In the rear of this room are two small rooms which are used for storage of apparatus. To the left of the building is a bathroom and storage room for clothes. At the right of the building is a gas room in which sulphur is burned during practice times. It is equipped with ladders and the usual apparatus for providing exercise for crews training. The station has four sets of Draeger apparatus, oxygen tanks and other standard equipment.

The officials of the Madison Coal Corporation were most courteous in contributing interesting information and in every way assisting in the preparation of this article, for which favors *Coal Age* is sincerely indebted.

A. J. Moorshead is the president and general manager of the company, G. E. Leyman, general superintendent, and Anton Daenzer, district superintendent. At mine No. 6, Harry Baines is top foreman, J. H. Miller mine manager, and Thomas Bee electrician.

An Effective Recovery Plant

There has been recently erected at Sheffield, England, a plant for the recovery of metallic particles and other byproducts from furnace fumes. It was discovered about 1906 that by passing gases containing solid dust and minute liquid particles through various forms and types of electrodes, charged with 50,000 to 100,000 volts of current, these dust and liquid particles could be precipitated.

Since that time the inventors of the process, which is of American origin, have not only successfully recovered valuable materials from waste fumes, but have also got rid of smoke and the smoke nuisance. Metals such as zinc, silver, copper, lead and aluminum have been recovered besides coal-tar and other byproducts of commercial value.

The experiments made at Sheffield are yielding satisfactory results, and other firms in Britain are now beginning to install this type of equipment in an encouraging fashion. The British Government has made one installation. The process appears to provide a thoroughly efficient remedy for the smoke nuisance, but the treatment of ordinary carbon fumes is unlikely to prove a profitable proposition. For that reason the installation of the necessary equipment purely as a smoke-abatement device is scarcely within the realm of probability.

Life and Care of Hoisting Ropes

SYNOPSIS—*Hoisting ropes usually have a modulus of twelve to fourteen million pounds per square inch of wire section. The best Lang lay rope is probably that with six strands of seven wires; it is more flexible than the regular lay and will take shorter bends. Opinions differ as to when ropes should be removed. In the anthracite regions it is the practice to replace them as soon as the stretch is out of them. Ropes should be re-cut and re-coned once every three to six months to prevent undue recurrence of strain at certain points. Reversing of ropes, end for end, is likely to give a false sense of security. Interlocking, locked-coil and galvanized ropes are rarely used in hoisting.*

SOME notes from the discussion of M. H. Sigafoos' paper,[1] read before the mining section at the Sixth Annual Congress of the National Safety Council, are worthy of record here. In general the ropes used for hoisting purposes in the United States have a tensile strength of about 85 or 90 long tons per square inch. The practice among operators of late has been to favor the use of plow steel, which has a tensile strength ranging from 105 to 120 long tons per square inch, but many manufacturers prefer to avoid the use of that material as much as possible because it succumbs sooner to fatigue when wound around a drum, the higher carbon content of the steel being responsible for its more rapid depreciation. Reverse bending, over the sheave and under the drum, injures high-carbon steel much more rapidly than it does low-carbon steel.

Modulus Should Not Be Assumed Too High

The modulus of 28,000,000 lb. per square inch referred to by H. C. Behr, in his discussion, applied to a square bar. In a wire rope a much different condition has to be considered, as the rope consists of separate wires which work upon each other when the rope passes around a drum or over a sheave, and the compression of the inner wires will take up some of the bending stress—that is, will reduce the modulus. In figuring out bending stresses in ropes, a modulus ranging from about 12,000,000 to 14,000,000 lb. per square inch is used. In using 29,000,000, a bending stress close to the ultimate breaking strain of the rope is obtained, which is not good practice. The wires in a 6-strand, 19-wire rope occupy about 50 per cent. of the area of the cross-section of the rope itself, which will reduce the modulus to some extent. If the 29,500,000-lb. modulus is used in figuring out the bending strength of the $\frac{5}{8}$-in. rope, the ultimate breaking strain of the rope is almost bound to be reached.

About 120 long tons is the highest tensile strength adopted for the material used in flat rope. In the lacing or threading of such ropes a soft wire must be used. This wire accomplishes a twofold purpose: It makes a neater job where the thread is turned back and laced through the different ropes, and it prevents inside abrasion of the wires in the rope itself. The soft annealed wire used as a lacing gets all the abrasion and the strands themselves get little.

Comparative data regarding the length of service given by ropes of regular and Lang lay types, operating under similar conditions, show that at two or three mines where $1\frac{1}{8}$- and $1\frac{1}{4}$-in. ropes are used, the average service of a regular lay rope has been about 24 months. Afterward the Lang lay rope was installed at the mines, and the average service, working under practically identical conditions, has been over 30 months. In one instance the Lang lay rope that was put on gave 34 months' service, as against an average of 24 months of the regular lay. The mines worked every day, and their tonnage outputs were practically the same per day. For this reason the tonnage hoisted in one year may be regarded as about equal to that of the next.

Wires in Lang Lay Not Laid Tightly

Because of the manner in which the strand is constructed the wires in a Lang lay rope are not laid so tightly as the regular lay. The wearing surface of the wires is much greater, and the wires will stand shorter bends without breaking than will those in a regular-lay rope. The rope is more flexible, and for some purposes gives better service than the regular-lay type. Also, Lang lay rope is less likely to kink, as it will tend to spring out and lay flat. It should be used with both ends fastened firmly, one end to the drum and the other having a closed, and not a swivel, socket. In the early history of Lang lay rope, particularly in the United States, the ropes were quite "twisty"; but now they are made so that they will lay as inert as the regular lay rope. After being in service a short while, they do not give any trouble. A Lang lay rope of 6-strand, 19-wire construction working on a clam-shell digger ran 90 days, as against 25 days of service rendered by a rope of the regular lay, the quality of steel being the same in both.

The Lang lay is undoubtedly the best lay for a hoisting rope, and the best type of Lang lay is a rope with six strands of seven wires in a strand; provided, however, the size of sheaves and the diameter of drums and all other conditions under which it has to work are adapted to a 6 x 7 rope.

The New Jersey Zinc Co. is using such a 6 x 7 rope with good success. The best basis of comparison is not the length of time that a rope has been installed, but the number of foot-tons of work it has performed, because one rope may be lying idle a greater proportion of time than another.

A 6 x 7 rope is more compact than a 6 x 19. The greater number of wires there are in a rope, the greater chance there is for the softening or opening of the strands; and this seems to apply more especially to the Lang lay rope, because the strands and wires are twisted in the same direction, whereas in the regular lay they are twisted in opposite directions. The wires are not so tight in a 6 x 17 or 6 x 19 as they are in a 6 x 7 rope.

[1]Published in "Coal Age," Vol. 12, pp. 928-931, issue of Dec. 1, 1917.

A 1-in., 1⅛-in. or 1¼-in. rope of 6 x 7 construction, with plow-steel wires, is a rather stiff rope, whereas the 6 x 15 or 6 x 17 construction, although not so tight as a regular-lay rope, is less likely to open up or "bird-cage." There is one advantage in the 6 x 19 construction. When a number of the outer wires are broken, there is still a good factor of safety left in the core of the strands, or in the inner wires of the rope, which, in a majority of cases, in 6 x 19 rope constitutes a section having about 40 per cent. of the breaking strain of the rope.

Remove Ropes When Stretch Is Out

And now as to the proper time to remove and renew a rope: There is a large coal company in the western part of Pennsylvania that uses ropes 1¾ in. and 2 in. in diameter for the purpose of hoisting men, and this company does not remove its rope until the rope shows 50 broken wires in any one foot. There are many people who, not being well acquainted with the construction and breaking strain of ropes, would regard a rope with 50 broken wires in any one foot as dangerous for use in hoisting men, but the Pennsylvania company to which reference is made has never had an accident, and it has found that the rope when tested, after that number of wires has broken, still possesses a large margin of safety. The inspectors on one occasion condemned a rope having these evidences of failure, but the manufacturer claimed that it was still safe. It was thoroughly tested, and it was found that it still retained about 60 per cent. of the original breaking strain.

In the anthracite region operators believe that a good rope is the best insurance of hoisting safety they can have. It is still a question as to when a rope has rendered its service and when it should be removed. A certain company in the anthracite region takes the rope off when the stretch is out, but if the stretch is not out in two years, the rope is removed without regard to that fact. All ropes at these mines are re-coned and re-cut every six months regardless of broken wires. It is an excellent rule to follow. If any broken wires are discovered or reported, that rope comes off at once.

Utility of Interlocking Ropes

Interlocking ropes have been tried for shaft sinking, with good results, and they are all right for a small load, such as a bucket, and they give good service. One rope that was used in sinking a deep shaft has to date been in use between six and seven years, and it is still in good condition. It is re-coned every six months. The time to take off a rope depends on the nature of its operation and the condition of the rope. Operators differ in their opinions on this matter.

About twelve years ago in the anthracite region a rope broke and dropped 10 men to the bottom of a shaft, killing all of them. The rope had been in operation, according to record, about nine years, and mine officials did not know how much longer. A sample of the rope about 8 ft. back from the fracture was taken and every wire of it tested. The wires in the rope were tested about 3 ft. from the fracture, after they had already been subjected to a breaking strain, and it was found that a tensile pull of 35 tons was required in order to break them.

The engineer claimed that the rope broke while the cage was being lowered, and that he did not know that the rope was broken until the end of it came into the engine room. The engineer was coming to a stop when the rope parted; he knew something had happened, but did not know just what. The men on the rope were supposed to stop at the level, and they were about at that point when the rope broke. The cage had no counterbalance, being a single-hoisting man cage, and was lowered by jerks.

One of the last jerks was at the level, and it is thought that this tug on the rope was the cause of its failure. The rope, no doubt, was able to take care of the load it was supposed to handle, and there must have been an undue strain put upon it; but whatever may have been the cause it was not brought out at the inquest. If the balance of the rope could stand 35 tons after it had already been broken, there must have been more strain than that put on it when it broke. It was pretty well rusted, it is true, but nevertheless, as has been shown, it required considerable strain to break it at a point only 3 ft. from the point of fracture.

The rated capacity of this 1¼-in. rope was 47 tons. Of course, there might have been a much larger amount of corrosion at the break, but that is not probable. It was not known whether the rope was ever dressed or lubricated.

Re-Cone to Change Points of Recurring Stress

It broke somewhere about 150 ft. above the cage, and there may have been some relation between the position of the break and the position the rope occupied in the sheave when the cage was at the landing. The lower end of the rope was always under tension, as the cage was left hanging with the brake on the drum. When the rope broke, it was at a point coming right under the drum, which was wound with an underbend.

Ropes should preferably be re-cut and re-coned every three months. When three or four feet of rope are removed from the drum end, those spots in the rope where the cage stops have caused permanent damage are shifted and the strain is removed to other parts of the rope.

Reversing a rope will not much increase safety, because most of the breakages have been in the lower end of the rope, showing that it is the lower and not the upper end that is subjected to the greater strain. A writer on the subject has said that in view of results the rope should be tapered the other way. For moderate depths that may be all right, as there is a great margin of safety for a small depth. When the depth becomes great such procedure is dangerous, and care must be taken in regard to the size of the rope, as it is one of the factors of safety.

In an instance where two interlocking ropes were used, one of the ropes ran perfectly, but the other rope "bird-caged,"—that is, opened up—an incident that caused the operators to abandon the interlocking type. Some companies make a practice of reversing the rope. When they have occasion to take the ropes off they frequently change them end for end, on the theory that this practice prevents special strains from continuously acting on any one point in the rope; but this undesirable condition is satisfactorily taken care of by re-cutting and re-coning the end of the rope.

Galvanized hoisting ropes have been little used in this country, as the galvanizing chips off readily in passing over sheaves and drums, and it is then of little or no value. Such ropes are used along the river front in New York City for hoisting on lighters, and here they are more successful. The majority of such ropes as are now in use have been imported. American manufacturers are making few galvanized ropes for hoisting purposes. Galvanizing has some effect on the actual bending strain of the wire itself. The loss in strength varies from 7½ to 10 per cent., according to the size of the wire. Lock coils are rarely used for hoisting purposes, but are popular for tramways and cableways because of the great wearing surface and the readiness with which they are gripped by the over-running carriage.

Moral Value of Fuel Administering

By J. Crow Taylor
Louisville, Ky.

While sitting in at a conference some time ago between a committee of coal men representing about 40 city dealers and a newly appointed committee on fuel administration which had been named by the state fuel administrator, I went through the sensation of passing from a critical and cynical mood to a feeling of appreciation of the work being done. The final realization was that what is seemingly farcical in this work is in reality excellent in its effect.

The administration committee and the coal committee quizzed each other back and forth in a manner suggestive of efforts at bargain driving on both sides. The coal men wanted to know how much in the way of margin the administration committee had a mind to allow the retail dealers. On the other hand, the chairman of the administration committee confessed that the first question he had planned to ask of the coal men was what margin they desired.

Finally a representative of the Federal Trade Commission who was present and who had participated in the adjustment of retail prices in a number of cities was appealed to for data on the subject, and by reference to his notes information was obtainable with which the two committees might readily have come to an understanding inside of an hour's time, and the matter would have been done and over with.

Moreover, the state fuel administrator by conferring with this member of the Federal Trade Commission or with any well informed man could in a few minutes have set the margin allowance for most of the retailers in the state without any further trouble or ceremony. Instead he had not only named an imposing committee for the city, which was the metropolis of the state, but had named committees for every county in the commonwealth. There are about 120 counties in the state and with from three to four members on each committee, it will easily be understood that their selection and appointment became quite an imposing task, calling for much detail and requiring considerable time and work.

Moreover, the committee appointed to administer the city fuel affairs got up an elaborate questionnaire which was mailed out to the trade. This took several hours' work with the coöperation of the coal committee to even formulate the questions, and has perhaps involved the burning of considerable midnight oil among the coal men in order to comply with the request for information. The trade is fairly familiar with these questionnaires. The amount of work involved seems stupendous, especially in view of the fact that the final result would not in any case bring about any appreciable change in coal prices.

It was the thought of all this that brought the critical cynical feeling. Then another thought came, that of the moral effect, the weight all of this would have in satisfying and establishing public sentiment. The coal trade has suffered in morale, or rather it has suffered in its standing in the public mind because of the increased prices and because of tirades of abuse appearing in the news and editorial columns of the daily papers.

I recalled while this meeting was going on, that following the first conference at Washington between a committee of coal operators and the Government authorities, one of the local papers had railed at the high prices named and had finally termed this meeting a conspiracy rather than a conference. It was perhaps this persistent attitude on the part of some papers that resulted in a succeeding order of lower prices, which later had to be increased again after a thorough examination to satisfy public clamor.

I began to understand why so much elaborate procedure instead of being looked upon as farcical (because an understanding and agreement could have been reached in a few minutes) actually became a momentous matter, of importance in satisfying the public mind that the coal dealers were not robbing them but were serving them fairly and only getting a reasonable profit.

If the committee of coal men and the administration committee had, for example, got together and in a few minutes adjusted the matter of local retail prices, which I am satisfied they could have done, loss of time and much detailed work would have been avoided, work that from a cold business standpoint would seem unnecessary. Yet the necessity for this work is plain if one but views it in the right light—it serves to satisfy the public that it is getting a square deal.

After committees of reputable business men, having the full confidence and respect of the community, go thoroughly into the details of the business and report upon the results, then there can no longer be a question remaining in the public mind of hold-up or conspiracy or unfair dealing. The skirts of the coal men are cleared beyond a question of doubt, and the moral value of this "administering" becomes easily apparent. Moreover, it is a value of considerable moment.

There can no longer be the usual outcry on the part of newspapers, whose editors lacking definite information are naturally clamoring for public welfare—men who assume that because prices are high the people are being held up.

So if one feels inclined to criticize at times and become impatient over the formality, elaborate ceremonies and the mass of detailed work involved in administering fuel, he should stop for a minute and think the matter over. There is a moral value that weighs much, and the coal trade today stands in need of a greater measure of public approval. In the final analysis it will be found that the fuel administering will prove a benefit to the coal dealers as well as a protection to the public.

Changing from Isolated to Central Station Power

By FRANK HUSKINSON
Lafayette, Colo.

SYNOPSIS—*It was decided to change from isolated station steam-electric power to energy purchased from a central station. After all preparations were completed the shift was made in a few hours without mishap and without a single calculation being found in error.*

At Sugarite, New Mexico, the St. Louis Rocky Mountain & Pacific Co. operates two mines, with an average daily production of 1000 tons of mine-run coal. The village, tipple, shops and power plant are located in the bottom of Chicorica canyon, with the mines on each side some distance up the mountain. The trips of coal are lowered to the tipple by gravity, a double-drum and heavy steel cables being used on the inclines. The loaded trip pulls the empty cars up. The trips of coal land on the tipple from the mine on opposite sides, the tipple being built across the canyon. Each side of the tipple has its own dump, but the chutes converge, delivering the coal to the railroad

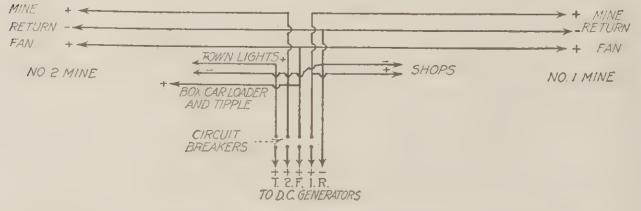

FIG. 1. DIAGRAM OF ORIGINAL POWER HOUSE CONNECTIONS

cars. The trips are hauled from inside the mines to the top of the inclines by electric locomotives.

The steam-electric generating plant located at the tipple furnished direct current at a potential of 500 volts, for the operation of the mine locomotives, ventilating fans, mining machines, pumps, tipple equipment, shops and town lighting system. The power plant equipment consisted of three marine-type boilers and two Ridgway simple, four-valve engines belted to the generators. The switchboard consisted of two feeder panels each with two separate circuits and two generator panels.

The arrangement of all feeder lines leaving the power house before the change to central station power was made is shown in Fig. 1. These consisted of three 4-0 bare copper wires to each mine, and two No. 4 weatherproof wires for the town lighting system. The fans for the mines were on the same circuit. The town lighting system was so arranged as to have two 260-volt lamps in series. The houses for the most part were of four rooms each and this made it necessary to have at least two lamps burning instead of one.

It was decided to put in central station power and have all outside machinery operated by alternating current. Direct current would thus be used only for the underground equipment. At the time of making the change the mines were working full force and every other Sunday, so that it was necessary to arrange to

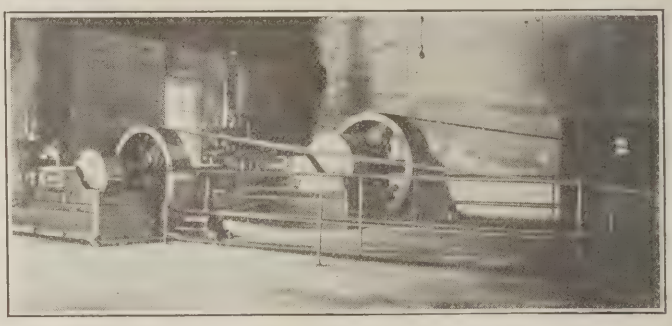

FIG. 2. POWER HOUSE ENGINES BELTED TO GENERATORS

make the change with the least amount of delay possible.

Fig. 2 shows the steam engines in the power plant. Directly in front of these engines the foundations were put in for the large synchronous motors that were to take the place of the engines for driving the generators. A 200- and a 100-kv.-a., 2200-volt, three-phase synchronous motor was placed directly in front of the engines with the pulleys lined up with those of the generators, as shown in Fig. 3. This arrangement did not interfere with the operation of the engines or generators.

The addition of three more panels to the switchboard was made for handling the alternating current—a panel for each synchronous motor and a feeder panel with two three-phase circuits on it. In order to make room for the equipment at the rear of the switchboard it was found necessary to move the original four panels forward a distance of more than 2 ft. This was done without interrupting service, and the three additional panels were then put in and all wiring completed. The three new panels were put in line with the original four, making the seven-panel board which is shown in Fig. 4.

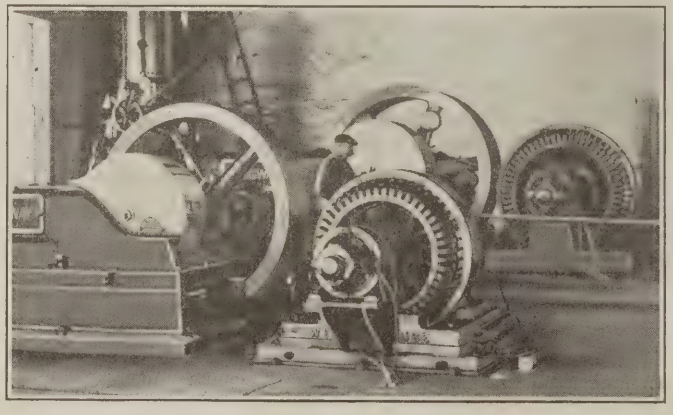

FIG. 3. MOTORS REPLACING ENGINES FOR DRIVING GENERATORS

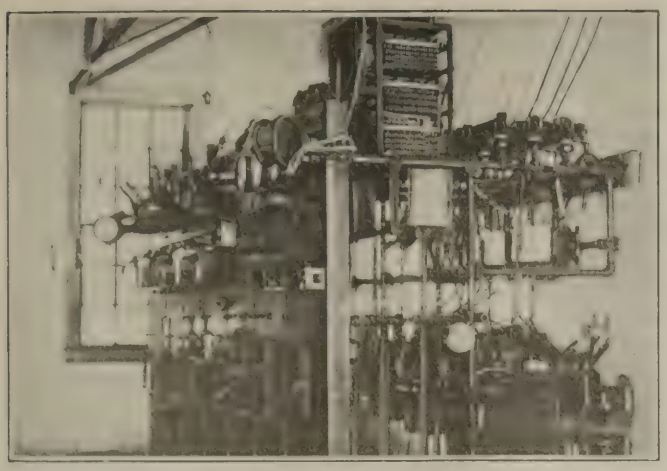

FIG. 4. SWITCHBOARD IN THE SUBSTATION

The three 4-0 bare copper feed wires to each mine were lowered to new cross arms placed on the poles 4 ft. below the top cross arms. Then three No. 6 bare copper wires were put in on the top cross arms from the power plant to each mine fan. A 15-hp., 2200-volt, three-phase induction motor was wired and made ready to be quickly slipped into the place of the old direct-current motor, and arranged so as to use the same belt. This was done at each fan, also a ½-kv.-a. transformer was installed at each fan, reducing the 2200 volts to 110/220 volts for lighting service.

The tipple equipment was run by a 15-hp., direct-current motor. A 20-hp., 2200-volt, three-phase induction motor was wired and made ready to be quickly put in its place, using the same belt. The main well pump was operated by a 15-hp., direct-current motor and also the shops. A duplicate of the fan motors was wired and made ready to be quickly put in, utilizing the same belts, etc.

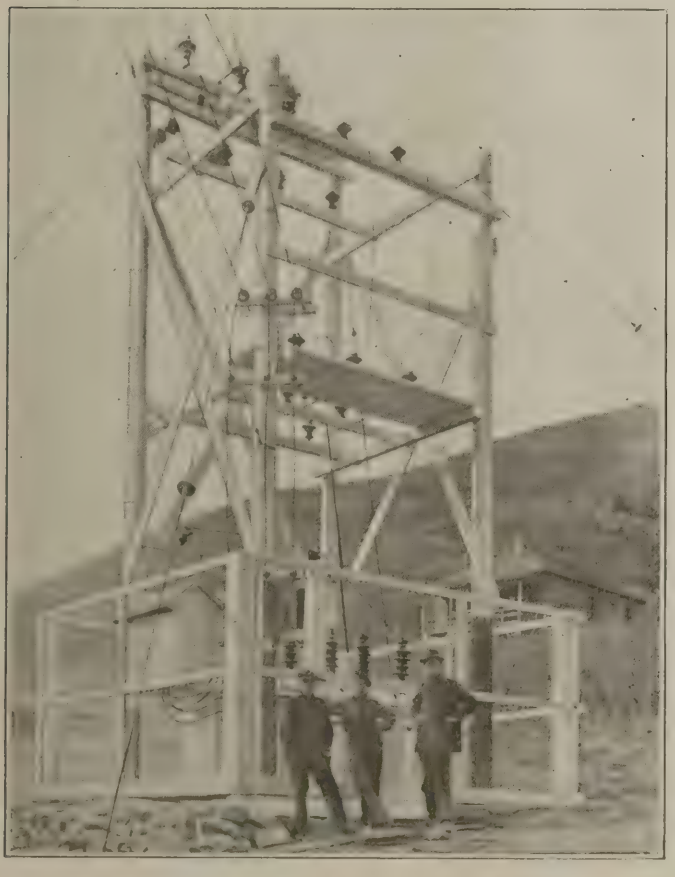

FIG. 5. OUTDOOR TRANSFORMING STATION

A third wire was run with the town lighting wires and five transformers were installed and wired up at different locations in the village and at the shops, reducing the 2200 volts to 110/220 volts for the lighting systems.

The central station power was received from Trinidad, Colo., a distance of about 35 miles. This power was delivered at the transformer tower at a potential of 44,000 volts, but was here stepped down to 2300 volts. The transformer tower was of the outdoor type and is shown in Fig. 5. This tower is only about 100 yd. from the power house. After all the new feeder lines and circuits had been installed the arrangement of lines was as shown in Fig. 6.

When all was in readiness for the change the mine was closed down at noon on Saturday, and by 7 o'clock that evening the generators, mine fans, tipple, shops and town lighting system were working on central station power. The entire system of house lights had to be changed from series to multiple wiring. This was done in three days. For temporary service one lamp socket in each series was plugged with a fuse and this allowed the use of the other socket.

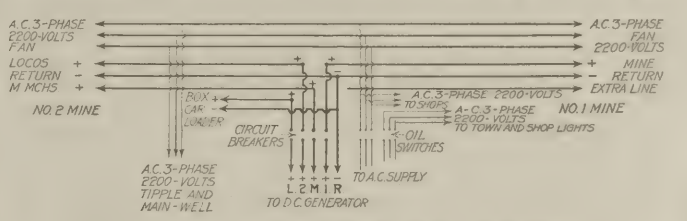

FIG. 6. DIAGRAM OF COMPLETED ELECTRICAL CONNECTIONS

The new installations were a success, and the operation of the substation now only requires one man where before it required the services of three high-priced men as well as the part time of several others. The substation is operated only during the day, as the fans, lights, shops, etc., do not depend for their current on the operation of the substation.

It will be noticed in Fig. 6 that the original direct-current fan breaker and switch were utilized, as was also the extra 4-0 copper feed line to No. 2 mine as a separate feeder line for the mining machines, thereby taking this load off of the feeder line for the mine locomotives. The circuit breaker and switch that had been on the town lighting circuit was utilized to advantage by placing it on the box car loader motor circuit. This was the only direct-current motor left in use outside. For various reasons it was decided to leave this motor in operation rather than change to an alternating-current machine. No mining machines were in operation at the No. 1 mine, so that there is now in place an extra 4-0 feed line to this point. It was decided to leave this line up for future use.

The change from isolated to central station power was successfully made without delay or accident. The use of induction motors on the mine-fan drives eliminates much of the trouble always experienced with the direct-current type of motor.

The change from a series system of lights at a high voltage to the standard 110/220-volt, multiple system is a decided improvement.

Northwest Needs Man Power

By CHARLES P. NORTON
Seattle, Wash.

SYNOPSIS — *The mines of the Pacific Northwest require more men in order to operate to capacity, and only by operating to a maximum will a local fuel famine be averted next winter. Living conditions in this region are excellent and opportunities for promotion many. Interrupted operation can be avoided by an extension of market. This would be particularly advantageous to the small mine.*

SHALL the country have a coal shortage next fall and winter, with all of its consequent suffering and delay to war work? Last winter the Pacific Northwest was the only section that did not suffer. Having just completed an investigation of conditions, I can forecast now what is liable to happen during the coming winter, even in the favored Pacific Northwest. This is a warning that should be voiced with vigor.

There is certain to be a shortage of coal in all markets. This will include household fuel, as well as steam coals, even if the output of the mines is maintained at the highest rate possible. In the Pacific Northwest, where conditions are most favorable, the maximum production cannot be reached unless at least 1000 additional laborers are found.

In all the mines of this region during June there was a shortage of men. The demand was great, the laborers were few, and men were leaving the mines every day —drifting into the cities and the shipyards. The mines of the Northwest were running June 15 at 75 per cent. of capacity. This was an improvement over the previous month, when the man power was about 60 per cent. The smaller mine owners are the ones who need the greatest encouragement from the Government in the way of enlarging the market, because, when the market becomes slack, the larger concerns with efficient and well organized sales organizations get the lion's share of the available business. The small mine is restricted, as a rule, in the possession of available capital, and cannot readily resume maximum operation after having suffered a slack period.

The percentage of lump or household coal produced is small, averaging 20 per cent. perhaps, of the total output. The remainder is used for steam coal and industrial purposes. If work slackens the mines can not produce household coals any faster than they can dispose of the 80 per cent. of finer (steam) coals. A good demand for household coals would make no appreciable difference.

What remedies can be applied? First, the market should be enlarged. A coal shortage exists all the time to the eastward. Therefore, coal should be kept moving east from the western district.

Harvesting and its demands upon man power will not affect the coal-mining labor supply to any marked extent, because few men of the mines go into the fields. The nationalities now represented at the mines are, in the order of the numbers employed, Italians, Swedes, Austrians, Slavs, Finns, Welsh and American.

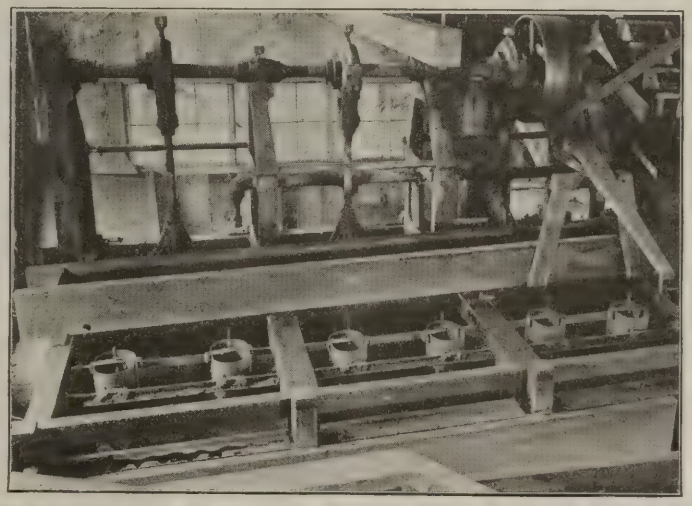
Working conditions in the Northwest are good. The mines are well ventilated, the air underground being as good as it is above, while the working places are cool and comfortable. At all the mines the men with families can rent comfortable cottages, with large yards on which grass has been sown; and that may be kept up for $7 the month, plus 50c. for water (which is of the purest) and 50c. for electric light. At the company stores provisions and necessities, including desirable delicacies, are sold at just enough above wholesale cost to pay the expense of operating the store. Here

many commodities are offered at prices less than those demanded at even the largest stores of the metropolis. Government food regulation may change all this, but the *a priori* facts are as stated.

Wages at the mines are satisfactory. Underground miners get $5.89 a day; laborers $5.20; outside laborers $4.65. The boy supply in June was adequate. Outside boys get $3.40; underground boys $4 to $4.10.

The miners may work on a contract basis, and some who do so earn as much as $300 a month. They pay $2.50 to $3.50 per ton for the best lump house coal—less than it costs to take it from the mine.

The latest equipment, to reduce necessary man power, has made possible the firing of boilers by a greatly reduced force at one of the mines. Waste coal is handled by three men, where before there were twelve. The work has been coördinated also and simplified.



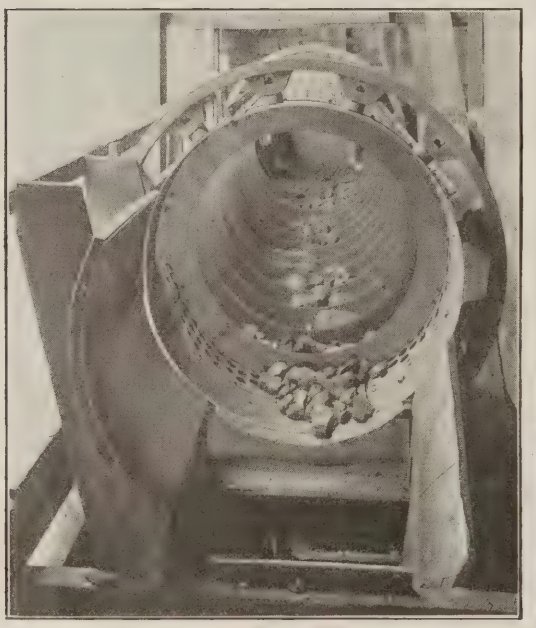
On account of slack production, coal cannot be produced and delivered any cheaper in summer than in winter. This might be done if production were full, but this is never the case in summer. The coal mines are dependent upon some one railroad line, as a rule, to deliver their output to market. In winter the rain and snowstorms impede the railroads and delivery of coal is uncertain. Teams and trucks cannot handle it.

Community welfare work at the mines is progressive. A welfare nurse has served admirably during the last three years. She started first to do her work with the school children, teaching cleanliness and sanitation. The children's teeth were examined and general work was done without cost. Small fees were paid by those who could afford it and who preferred to do so. Eyes were examined and glasses were supplied. Physicians in Seattle generously donated their services, or accepted small fees from those who desired to pay. This beneficent work started before the war, and during the slack market period, when the men were working half time and the foreigners were sending their surplus money to the "old country," so that they had a narrow margin above actual living expenses.

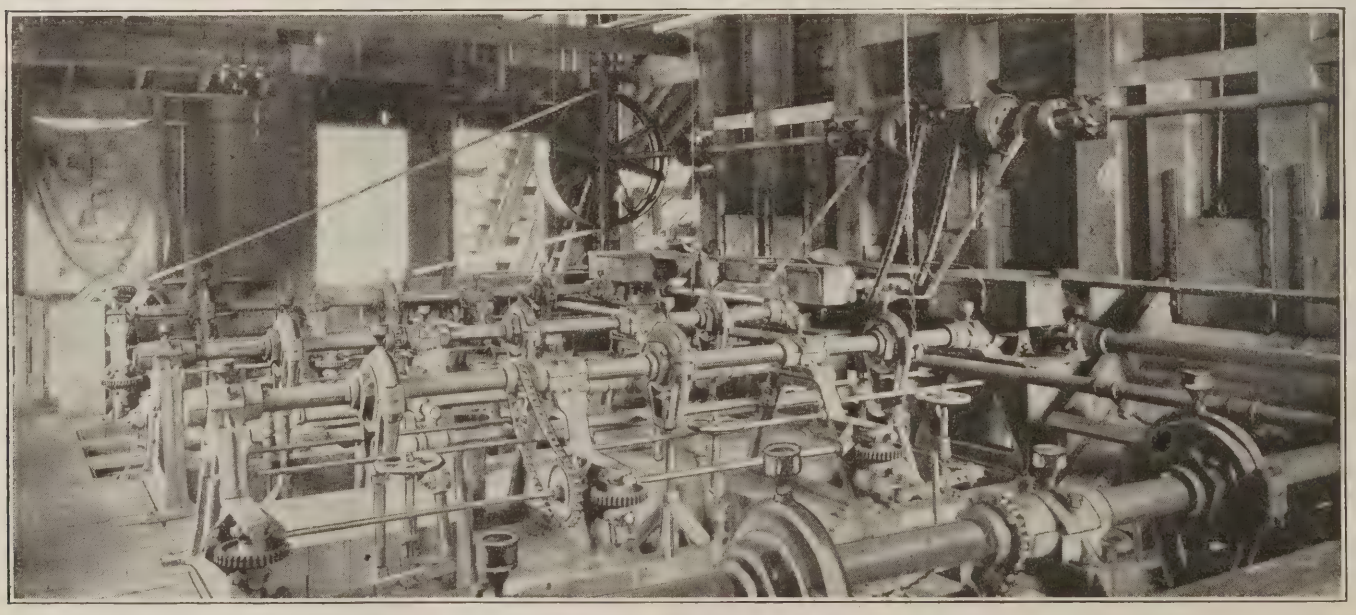
A model cottage was built at Black Diamond—the Seattle coal center—to show the miners how to establish a comfortable home, easily within their income. Women and children met frequently in the cottage, to learn scientific methods of housekeeping, cooking and sewing. This work has spread to all the camps and, in some way, reaches into the daily lives of all employees.

Social gatherings are held regularly at the mines and athletics is encouraged. The Black Diamond soccer team, for example, is noted for its championship performances in the cup tourneys of Seattle. Most of the coal-mining towns have baseball parks and also picnic and amusement grounds. Some places, especially Franklin and Coal Creek, have excellent bands. Practically all of the married miners have war gardens.

The coal-mining communities of the Pacific Northwest were among the first to inaugurate the practice of contributing regularly to the Red Cross. All the miners regularly give 1 per cent. of their wages, while the officials give 1½ per cent. In the third Liberty Loan, Black Diamond challenged all other towns of its size in America to equal its subscription. Its allotment was $6000 but its cash subscription was $63,650. The thrift stamp campaign also is well organized and the miners are continually increasing their investments. At each mine in the Pacific Northwest there is a committee of protection, to safeguard against treasonable acts of aliens. These organizations are formed exclusively of the employees, who constantly exercise the strictest surveillance over everything.



VARIOUS TYPES OF PREPARATION EQUIPMENT IN USE IN THE PACIFIC NORTHWEST



STREET IN A NORTHWEST MINING TOWN

REVOLVING SCREEN FOR SIZING COAL

TIPPLE AT A BRITISH COLUMBIA MINE

A BATTERY OF JIGS IN A PACIFIC NORTHWEST COAL TIPPLE

Opportunities for the men to advance their positions at the mines are excellent indeed. There is always a demand for experienced men who can qualify as foremen, superintendents, firebosses, etc. For example, a few years ago a certain employee of the Pacific Coast Coal Co. was driving a mule 12 hours a day for a wage of $1.80. He is now a superintendent. A chainman, who saw his first coal mine with the same company, a few years ago, is now a vice-president in charge of mining and general operations. There are many similar examples. Merit here comes to the top, and there is always room at the higher levels. In fact a majority of the officials of the Pacific Coast Coal Co. started at the bottom as miners or laborers, and a majority of the executives and foremen are men from the ranks.

The whole Northwest is now being combed, by a unique personal method, to find experienced men for the mines. One man, for example, having an extended personal acquaintance with miners, devotes his entire time to looking them up and inquiring for others. He frequents the hotels and amusement places and every miner whom he meets tells him how to locate others. This system is producing good results and man power is being somewhat augmented.

In these mines most employees can save at least 50 per cent. of their wages. Many of them are putting away more. The aggregate saving is thus enormous. The wash-houses at the mines, installed by the companies, become the property of the employees through the payment of a nominal sum monthly to cover interest and depreciation. The houses are equipped with shower baths and baskets for clothing.

The hospital association service, controlled by the men, costs $1 per month for each worker, and they employ their own physicians, who attend the miners and their families.

At least 500 more miners, preferably men with families, are wanted in the Pacific Northwest in order to secure maximum operations during the summer, fall and winter. If they are obtained, there will be no local shortage, and with maximum operation there will be a large surplus of coal for the Eastern markets.

On account of Seattle's importance in ship production for the Emergency Fleet Corporation, it is desirable that every effort be made to prevent a shortage of coal. In addition to ships the 1200 industrial plants at the Seaport of Success are now on a war efficiency basis and will be working night and day from now till the end of the war. Even after the close of hostilities they will be kept going full blast for years to supply local demands and those of Alaska, Siberia and the Orient.

Plant of Conemaugh Smokeless Coal Co.

By Charles Martin
Smokeless, Penn.

The Conemaugh Smokeless Coal Co. has made many modern improvements recently at its plant at Robindale, Penn. This village is located about 8 miles west of Johnstown, on the main line of the Pennsylvania R.R. and directly across the river from the town of Seward, with which it is connected by a swinging bridge.

The town is laid out with avenues paralleling the railroad and streets running at right angles thereto. A large plot near the center of the town has been left open and will be used as a playground and amusement park. The streets are graded and provided with tile sewers, while each street intersection is illuminated by an electric light.

The houses are of modern construction, being built of tile. Four- and six-room bungalows, five-room double and six-room single houses have been built. All are electrically lighted and provided with running water.

The town water supply is derived from a mountain stream. From this stream the water is pumped to a tank at the works that has an elevation of about 70 ft. This gives ample pressure everywhere in the town, but the water mains are also connected to centrifugal pumps at the mine, so that these can be used in case of an emergency, such as a fire.

SURFACE PLANT OF THE CONEMAUGH SMOKELESS COAL CO. AT ROBINDALE, PENN., AND A VIEW OF ONE OF THE STREETS

The coal is reached both by shaft and slope. The mine is electrically equipped throughout and the coal undercut by means of Sullivan shortwall machines. It is hauled to the shaft bottom by electric locomotives and hoisted on self-dumping cages. At the top of the tipple it is discharged upon a conveyor that carries it to the railroad cars.

A new 9 x 4½-ft. double-inlet reversible Sirocco fan, driven by a 205-hp. McEwen engine, to which it is direct-connected through the medium of a Frankie coupling, has recently been installed. This machine is capable of producing 200,000 cu.ft. of air against a 4-in. water gage. At present, however, it will be necessary for this fan to operate only at 82 r.p.m., at which speed it will produce 57,000 cu.ft. of air per minute.

Lunge gives a list of over 200 compounds which have been found or may reasonably be presumed to exist in coal-tar. In contrast with gaseous hydrocarbons those which are liquid and solid contain a much larger number of carbon atoms in the molecule and consequently deposit more carbon when they are cracked.—*Bureau of Mines Bulletin No. 135.*

Who's Who In Coal Mining

F. E. Herriman

F. E. Herriman, who was recently appointed to the new position of Coal Traffic Manager of the New York Central, began railroad service in 1874 as clerk to the superintendent of the Cincinnati, Sandusky & Cleveland, and served consecutively as secretary to the general manager, assistant to the president, and purchasing agent of that road, and coal and lumber agent of the Chesapeake, Ohio & Southwestern, at Louisville, Ky. In 1885 he was made General Freight and Passenger Agent of the Beech Creek, where he remained for 14 years. He then came to the New York Central as division coal agent of the Beech Creek district, and in 1901 was made General Coal Agent of this road and of the West Shore, where he remained until Oct. 1, 1905. He was also General Coal Agent of the Boston & Albany and other New York Central lines. Since the acquisition by the New York Central of the great Beech Creek coal properties and the railroad extensions into that bituminous coal region, Mr. Herriman has had charge of the commercial development. The problem was not the simple one of mining coal and selling it. In his relations with the other coal carriers, as well as with the users of coal, his work was probably as difficult and delicate as any that comes to a traffic officer. His was the duty of "butting in" with a new supply and a new line, and of course his instructions were to get a fair share of the business.

F. E. HERRIMAN

He continued as Coal Traffic Manager of the New York Central lines east of Buffalo until he was invited in September of last year (after 33 years' service as a traffic official of the New York Central lines) to join the staff of President A. H. Smith as the active head of the coal development policies of the New York Central lines. On June 19 Mr. Herriman was appointed vice president of the Clearfield Bituminous Coal Corporation.

Vancouver Island Production in May

The coal produced by the Vancouver Island (B. C.) mines during the month of May totalled 143,379 tons. This is 4718 tons less than was produced in April, which is accounted for by the May holidays. The tonnage produced by the various collieries was as follows:

	Tons
Canadian Western Fuel Co., Nanaimo colliery	63,807
Canadian Collieries (D) Ltd., Comox colliery	50,163
Canadian Collieries (D) Ltd., Extension colliery	19,781
Pacific Coast Coal Mines, Ltd., South Wellington	7,660
Nanoose Collieries, Ltd., Nanoose colliery	1,968
Total	143,379

The coal produced by Vancouver Island collieries for the five months up to and including May, 1918, totalled 717,266 tons, as follows:

	Tons
Canadian Western Fuel Co., Nanaimo colliery	328,299
Canadian Collieries (D) Ltd., Comox colliery	232,255
Canadian Collieries (D) Ltd., Extension colliery	97,781
Pacific Coast Coal Mines, Ltd., South Wellington	42,764
Nanoose Collieries, Ltd., Nanoose collieries	16,167
Total	717,266

In spite of the fact that the Jingle Pot Mine, Nanaimo, has been closed all year; that Nos. 1 and 2 slopes of the South Wellington colliery of the Pacific Coast Coal Mines have been abandoned; that No. 4, Extension colliery, of the Canadian Collieries (D), Ltd., also has been abandoned; that No. 6 Mine, Comox colliery, Canadian Collieries (D), Ltd., has been closed; and that some of the other mines have been put on single shift because of lack of labor, the tonnage of the Island mines has been maintained to last year's standard, within a few thousand tons. To date the Western Fuel Co. has made a gain over last year's tonnage of 60,000 tons and the Nanoose collieries of 9786 tons.

New Plant for Connellsville Region

A corporation known as the Rainey-Wood Coke Co. has been organized by the W. J. Rainey interests, operating coal mines and coke works in the Connellsville region, and the Alan Wood Iron and Steel Co., with blast furnaces and steel works at Swedeland, Penn., for the purpose of constructing a large byproduct coke plant of 330 ovens at Swedeland, Penn. The coal for this plant will be furnished by the W. J. Rainey mines in the Connellsville region. Work has been started on the first unit of 110 of these ovens, and it is expected to have the plant in operation within fourteen months.

This first installation will supply coke, gas and tar to the Alan Wood Iron and Steel Co. and will have sufficient additional capacity to furnish foundry coke for the Eastern market. A complete byproduct recovery plant will also be constructed for the purpose of furnishing sulphate of ammonia and toluol to the United States Government.

It is proposed to install the remaining units at the earliest possible date, in order to insure a continued coke supply for the independent blast furnaces in the Schuylkill and Lehigh Valleys.

After the soot has once been formed it is difficult to burn it in the atmosphere of the furnace. This fact has been observed by many investigators, and some of the early writers on combustion even considered soot as noncombustible.—*Bureau of Mines Bulletin No. 135.*

Alleges Great Profits Were Made by Many Coal Operators

Nothing short of a sensation was caused in Washington by the report of the Federal Trade Commission dealing with the profits of various industries. The commission finds that the bulk of the coal production has been marketed at large margins under the Government's prices. After reviewing the situation in the flour-milling industry, in which large profits were made, the commission says:

The situation in coal gives still another angle of view to the same problem. Maximum prices were fixed by territorial divisions. Many of the coal producers have not taken the maximum, but due to the fact that in a given field there is a very wide range in the cost of the coal produced in that field, it follows that certain low-cost producers have made very large margins under the system of governmental fixed prices for the field. Many high-cost producers have made small margins. The bulk of the production of course enjoys the large margin. Information on the return on the investment, now being collated, will reveal the exact amount of profit. Percentages of profit worked upon investment will obviously be very large in the case of low-cost companies.

The experience with steel, flour and coal shows that a high stimulating fixed price, while stabilizing an ascending market, produces an economic situation which is fraught with hardship to the consuming public and with ultimate peril to the high-cost companies through increasing the power of their low-cost competitors.

Continuing, the report has the following to say with regard to coal:

In connection with the distribution of coal it may be pointed out that prior to the official regulation of jobbers' and of retailers' margins in August, 1917, there was evidence that many of the margins were unduly high when compared to the pre-war margins. Details can be found in the Report of the Federal Trade Commission on Anthracite and Bituminous Coal, June 20, 1917. Since the regulation was established most of the jobbers' transactions have been carried on within the fixed margin, and whenever violations have been detected the jobbers have been forced to refund the overcharges. It should be understood that jobbers' and retailers' margins do not represent net profits alone, but also include all expenses incurred by them from the time coal is purchased until it is sold.

Generally speaking, the bituminous coal operators in 1917 had very much larger margins than in previous years. While in 1916 the margins (what operators actually received for coal sold over f.o.b. mine cost) may be regarded in some cases as lower than normal, yet the margins of 1917 were often two or three times the normal return. In the figures for 1916 and 1917, mentioned below, return on investment must be covered in margins shown. The increase of margins is illustrated by an examination of the returns for 1916 and 1917 of 23 typical bituminous coal companies in the central Pennsylvania field. The average margin of these companies in 1916 was 20c. per ton, and in 1917 was 90c. The highest margin for any company of the 23 companies in 1917 was $1.85. The corresponding margin for this company in 1916 was 41c. Similarly, the lowest margin for any of these companies in 1917 was 27c., the corresponding margin for the same company in 1916 being 13 cents.

Maximum coal prices f.o.b. mines were authoritatively fixed Aug. 21-23, 1917, by executive order, and subsequently modified by the Fuel Administration. Contracts made before that time were not invalidated. In some fields as high as 90 per cent. of possible production was sold under contract prices. While some contracts were below legal maximum price, probably much the greater part of the coal sold under contract went at prices substantially in excess of legal maximum prices fixed for current sales.

April realizations contain relatively little coal sold on contracts made prior to Aug. 21, since most such contracts expired Apr. 1, 1918. Sample reports for April operations, covering 12,619,274 tons actually mined in West Virginia, Pennsylvania, Ohio, Indiana, Illinois, and Kentucky, show an average margin between claimed f.o.b. mine cost and actual realization from sales of about 54c., as against a pre-war margin of an average of 10 to 15 cents.

In anthracite the average receipts per ton, including all sizes, during the year 1914 (13 companies, producing 79 per cent. of the total tonnage in 1916), were $2.86 per ton. The average receipts per ton of anthracite, including all sizes, allowing for later obligatory summer discounts on prepared sizes, during the period January-March, 1918 (six companies, producing 50 per cent. of the tonnage in 1916), were $4.26 per ton. The average labor cost increase per ton since 1914 was $0.76, and if this is deducted from the 1918 average receipts per ton an increase of $0.64 per ton (or 22 per cent.) in average receipts is indicated without allowance for increased cost of supplies and general expense.

In Charge of Clean Coal Inspectors

Inspectors charged with examinations to determine that the clean-coal regulations of the Fuel Administration are being carried out have been placed under the immediate direction of J. M. Roan. Mr. Roan's headquarters will be at Columbus, Ohio.

To Save Considerable Coal by Economy in Industrial Power Plants

Fully 20,000,000 tons of coal will be saved this year, the Fuel Administration expects, as an outcome of savings which are being effected at power plants. There are 250,000 industrial power plants in the country. At many of these, the amount of waste is considerable. Every power plant east of the Mississippi River is to be visited by an inspector and given a rating based on the thoroughness with which the owner of the plant carries out the conservation recommendation. The plan is based

on the use of the present equipment without the installation of fuel-saving apparatus.

Administrative engineers will be in direct charge of this work. Thomas R. Brown, of Pittsburgh, will direct the conservation program in western Pennsylvania. George R. Henderson, of Philadelphia, will be in charge in eastern Pennsylvania. The campaign in the State of New York will be directed by Edward N. Trump, while W. R. C. Corson, of Hartford, will be the engineer administering the work in New England. Henderson W. Knott, of New York, will manage the field force from headquarters in Washington.

Price of Lump Cannel Coal Increased

On securing a permit from the Fuel Administration, lump cannel coal may be sold at $1 per ton in advance of the run-of-mine price of bituminous coal in the same district. An additional charge of 50c. is permitted if it is loaded in box-cars.

New Ohio Coal Prices Announced

Price revisions for Ohio were announced the latter part of last week and were distributed by the Southern Ohio Coal Exchange. As the new prices were made effective at 7 a.m., June 29, the changes were made at short notice. The most noteworthy readjustment made was that of naming counties and townships in the making of prices. The coal is not classified solely as of thick- and thin-vein, as in the former price list.

The counties of Hocking and Athens, and the south half of the township of Monroe, in Perry County, is defined as the thick-vein field, and the new prices are: Mine-run, $2.55; prepared sizes, $2.80; slack, $2.30.

Prices for Bailey Run, or No. 7 seam, which is defined as thin-vein, are: Mine-run, $2.95; prepared sizes, $3.20; screenings, $2.60. In Guernsey and Muskingum Counties, which is also classed as thin-vein, the prices are: Mine-run, $2.70; prepared sizes, $2.95; slack, $2.45.

In Meigs County, which is known as the Pomeroy Bend field, the prices are: Mine-run, $2.80; prepared sizes, $3.05; screenings, $2.55.

Jackson prices are reduced about 15c. on the ton to the following: Mine-run, $3.45; prepared sizes, $3.70; screenings, $3.30.

Prices in eastern Ohio, or Pittsburgh No. 8 seam, are unchanged.

Weekly Production Statistics

Production figures for the week ended June 22 are as follows: Bituminous coal, 12,016,000 tons; anthracite forwardings, 41,170 cars; beehive coke, 604,000 tons; byproduct coke, 489,542 tons. With the exception of byproduct coke, each of the totals is a decrease, as compared with the accomplishments of the week preceding.

While the decrease in the production of bituminous coal was 5 per cent., as compared with that of the week preceding, the output was still safely above 12,000,000 tons. The fact that that figure has been exceeded for three consecutive weeks has caused great encouragement at the Fuel Administration. The total production for the last twelve weeks has been 137,705,000 tons. The production for the week ended June 22 was 60 per cent. greater than that during the corresponding week of 1917.

The decrease in anthracite shipments was 1.9 per cent., as compared with the week preceding, but is above the average number of cars forwarded weekly.

Shortage of labor was the only important factor interfering with the production of beehive coke, during the week ended June 22. Owing to the inability to secure yard labor, it is estimated that the production of 106,000 tons of beehive coke was lost. Cars could be had in ample quantity at practically every oven. Byproduct ovens were operated at practically 90 per cent. of maximum capacity. Necessary repairs to plants was the chief limiting factor, to which was added some loss of production, due to labor trouble.

Figures referred to in the foregoing are estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Needless Illumination To Be Cut Out

Failure on the part of nearly every city and town in the country to prevent a waste of electricity has made necessary new action on the part of the Fuel Administration to save the coal which is being used for needless illumination. This action is taken, Dr. Garfield says, because "the country needs now—and for the whole period of the war will need—more coal than it can possibly produce and transport."

Profits Made by Coal Companies Exaggerated

Of the 2698 corporations engaged in mining coal during the year ended Dec. 31, 1916, only 1833 were conducted with a profit. This fact was brought out when the Treasury Department made public its compilation of income-tax returns for 1916. The disclosures of this report are held to be the best indication that the conclusions of the Federal State Trade Commission with regard to profits of coal-mining companies are exaggerated.

Brief Washington Notes

R. C. Norfleet, of Winston-Salem, has been named state fuel administrator for North Carolina.

The United States Fuel Administration has taken direct charge of fuel requirements for the District of Columbia.

Joseph H. Frantz, of Columbus, has been appointed fuel administrator for Ohio. He is vice president of the Columbus Iron and Steel Company.

Twenty-five additional inspectors have been appointed by the Fuel Administration to guard against the shipment of coal for bunkering purposes which is not up to standard.

Back up those who are offering their all—buy War Savings Stamps.

When you buy War Savings Stamps you do not give—you receive.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Already restrained as to the prices at which they sell their coal, the operators are now to be restrained as to the wages they shall pay. This restriction they are quite willing to approve; in fact, it seems to have been first advocated by certain of them. Central Pennsylvania appears to have had more than her share of fly-by-night mines which were ready to pay all manner of bonuses and ready to give all kinds of prizes. No one objects to anything which will encourage production, but the action of bonuses and prizes was not so marked apparently in the stimulation of output as in the increase of turnover. The men were always being coaxed from the employ of the mines paying the regular wage scale to enter some other mine where a lordly bonus added to the earning.

Central Pennsylvanians have always been keen competitors. They formerly competed bitterly as to sales and railroad cars; now their competition is for men. In either case the energy of their business methods results in making their industry unprofitable. The drift of men from mine to mine makes it hard for the railroad to apportion cars equitably, because the capacity of a mine depends on its working forces, and where men are drifting around, no one on the railroad can tell how many cars any mine should have. Moreover, when men are shifting back and forth with their families, there is a minimum of output and in the long run no one is the richer.

NAY AUG IS GOING TO TRY THE NINE-HOUR DAY

The anthracite region's difficulties are but little changed, though the energy which the operators are exhibiting in "Win the War" propaganda promises success. The Nay Aug Coal Co., a small company at Dunmore, in the Scranton district, has induced its men to work 9 hours.

In the Lansford district many men are refusing to sign production pledges. They say it requires of them too uncompromising a promise to work whenever physically able, but their contract already demands this and nothing less than this. They cannot strike now without violating binding obligations. But this new pledge being signed personally, not collectively and by delegate, is more solemn than the wage agreement, even though it is not balanced by any return pledge on the part of the operator. The mine workers, therefore, balk at signing it. It is no time for such a decision as they will soon find if they persist in working irregularly.

In Illinois, Belleville and Taylorville have been chosen two of the subdistrict headquarters. Next year's subdistrict convention in the Belleville district goes to Collinsville. A labor temple will be built in Belleville after the war and every subdistrict will probably have a similar building to house its activities.

CHARGED WITH THREATENING TO BLOW UP MINE

Dominick Coma, of Edwardsville, Ill., is under arrest, accused of threatening to blow up a mine at Troy, Ill. He is also said to have interfered with the draft. It is stated that he drew the pay checks of two miners who disappeared just before the time at which they were required to register for the draft.

Because Senator L. V. Sherman has denounced the labor disturbances in and around Springfield as unpatriotic, the mine workers of that district to the number of 12,000 resolved recently that "by his tactics of stirring up class hatred he is rendering aid and comfort to the enemy" and should be "interned during the war."

The operators of this country have always been opposed to propaganda. Nothing has been harder than to arouse them to the necessity for an expression of their views as to the way in which their employees should meet the industrial conditions. But at last in a fuller measure they are beginning to realize their leadership.

When they come to present their views to their men, perhaps those views will be somewhat modified and amended and that perhaps will not be at all unfortunate. It is well to be obliged to study the reactions of others. It sometimes enables one to see the other man's point of view, which will be found not entirely devoid of reason.

In the Southwest the publicity campaign has taken the form of issuing the minutes of a conference relating to the production of clean coal in large quantity. Perhaps the mine workers will wade through this cumbrous document and learn that the nation and not merely the operator is calling on him for clean coal. But the Southwestern mine worker must be a studious fellow if he will do more than glance at the lengthy pamphlet with its fine type, copiously signed as are the resolutions in it, on behalf of the union, the operators, the fuel administrators and the coal inspectors.

HOLD A CLEAN-COAL CONFERENCE IN SOUTHWEST

The conference referred to met on June 17 at Kansas City and was attended by the Southwestern Interstate Coal Operators' Association, the Oklahoma Coal Operators' Association and the Iowa Coal Operators' Association, the presidents of the union in District 13, Iowa; District 25, Missouri, and the vice presidents of the union in District 14, Kansas, and District 25, Missouri. H. N. Taylor was present as district representative for Production Zone 17, with Charles Means, who is general manager of the Inspection Department of the United States Fuel Administration.

A patriotic poster issued by the Southwestern Interstate Coal Operators' Association tells the story regarding the need for more coal in words that cannot fail to appeal.

It is interesting to notice that mine workers in Illinois are now striking to compel the employment of a woman at a mine job. On the other hand, a few days ago the anthracite miners were threatening to strike to prevent the employment of women, and they could not be pacified till the women were ousted.

But neither operator nor mine worker dare be satirical about this. The story could be told in another way. The operator in Illinois who refuses to employ this woman and would rather have a strike of his men than engage her is acting in a manner almost exactly contrary to the operating company in the anthracite region that put on several women and tried to make the mine workers permit of their employment.

Some special reasons made the mine workers favor her and doubtless special reasons may make her employment undesirable to the operator. But on the face of the situation as presented it is not possible to declare either mine workers or operators the more unjustified in their contradictory stand, but this should be added, that a strike, especially a strike to disturb the present status, is not now justifiable.

Will Not Collect Death Benefits

The Susquehanna Collieries Co., with many other coal corporations in the anthracite region, has a matter of dispute with its employees that should be settled without delay if steady production is to be maintained. In the issue of June 15 the difficulty of the Lehigh & Wilkes-Barre Coal Co. in the matter of funerals was discussed. The Susquehanna company has a somewhat similar trouble. Three men were killed in a cave-in of the Short Mountain colliery, one of the Susquehanna operations, on June 17. On June

20 and 21, 1000 men employed at that colliery refused to work, declaring that such work on the day of the funeral of a victim of the operation of the mine was against the provisions of their local union.

It appears that the Susquehanna Coal Co. at the request of the mine workers' union agreed that whenever one of its men was killed it would deduct 25 per cent. from the wage, for a single day, of every mine worker employed at the plant. After the company was required by law to compensate the mine worker's family whenever an accident occurred, this seemed an unnecessary provision. The argument of the company was that the men could make any private collections they saw fit, but the Susquehanna Coal Co. did not feel that it was right to compel men to pay a compensation to people who were already well protected by law.

This is the attitude of the Susquehanna Collieries Co., which has recently succeeded the Susquehanna Coal Co. The funeral of two of the three victims occurred on June 20. The third was buried on the day following. The employees of the colliery observed both days as a holiday, declaring that only in this manner would the company suffer them to show their sympathy with the bereaved. About 4000 tons of coal would have been mined in the two days had the miners worked steadily. It must be understood that these funeral strikes begin and end on the day of interment of the unfortunate mine worker involved.

Which Men Aid Their Country Most?

Loyalty demonstrations still occur from time to time in the Illinois field. In Edwardsville, where a jury acquitted the lynchers of Robert Paul Prager, German enemy alien, 35 men went the other night to the home of Jacob Gent, a coal miner. This man's loyalty had been brought into question because he wrote to Governor Lowden denying the alleged disloyalty of the Rev. J. D. Metzler, a Catholic priest, who had been driven out of the town. He was made to swear his loyalty and kiss an American flag, which was then erected in front of his home.

Now that the railroads are giving a better car supply, the wonderful efficiency and patriotism of some miners and companies is being attested by the large earnings some of the miners are now making. It may be added that such efficiency and patriotism is not only creditable to those exhibiting it, but pays big dividends to the efficient and patriotic. Among all the miners of large production in Illinois George Weiss, of Freeburg, in St. Clair County, claims the first place. In his last pay envelope was $240. It was the earnings for only two weeks' work, eight hours a day. During that time two half days of time were lost. The previous record for two weeks' work in the Illinois field is said to have been $198. Men who quietly occupy themselves in mining coal do more for their country than those who run around hounding men like Prager and Gent against whom no charges can be substantiated.

Banning Bonuses and Overpayments

A meeting of the coal operators of the District of Central Pennsylvania, was held at Washington, D. C., on June 26. It was called to consider a remedy for the evils growing out of the so-called "bonus system." The following resolution was unanimously adopted:

"Whereas, it has been brought to our attention by the Fuel Administration that many coal operators are granting bonuses and other inducements for labor, thereby causing unrest, unusual labor turnover, and interfering with the maximum production of coal;

"Resolved: That we recommend that the Fuel Administration close down those coal mines in central Pennsylvania, as being wasteful and too uneconomic to operate during the present war, where the wage rates or conditions offered exceed the rates and conditions in effect under the Washington Agreement, as applied to the Central Pennsylvania field, or decisions of the U. S. Fuel Administration thereunder.

"That a board of five members be constituted by the Association of Bituminous Coal Operators of Central Pennsylvania, which shall determine in each case, after hearing the statement of the operator, whether he is operating wasteful and uneconomic mines such as are above described. The findings and recommendations of this board are to be subject to appeal to the Fuel Administration by any aggrieved party."

This arrangement having the approval of both the Association of Bituminous Coal Operators of Central Pennsylvania and the Central Pennsylvania Coal Producers Association, was naturally regarded by the United States Fuel Administration as a practically unanimous request from the coal industry in central Pennsylvania. The Fuel Administrator approved of the proposal but ordered that the board should have nine members, five to be nominated by the Association of Bituminous Coal Operators of Central Pennsylvania and approved by the Fuel Administrator and four others, consisting of the Presidents and Secretaries of the Association of Bituminous Coal Operators of Central Pennsylvania and approved by the Fuel Administrator and four Association.

The authors of the resolution proposed that a penalty be provided for those violating the Washington agreement, but this did not satisfy the Fuel Administration.

Peoria Subdistrict Organized

Subdistrict No. 2, District No. 12, United Mine Workers of America, has been organized at Peoria. The new subdistrict includes Peoria, Tazewell, Fulton, McDonough, Rock Island and Mercer Counties, as well as the mines at Sparland, Ill. W. E. Sherwood, of Canton, was elected president; M. Gallagher, of Hanna City, vice president; and W. H. Thrush, of Hanna City, secretary and treasurer. The compensation of the president and secretary-treasurer was fixed at $2035 and expenses per annum. The compensation of the vice president was placed at $6.50 per day when actually on duty. The headquarters will be at either Peoria or Canton. The new subdistrict was organized in a blaze of patriotic fervor and a determination to produce coal for the nation in greater quantities than ever before.

Illinois Miners To Mine More

President Frank Farrington, of the Illinois miners, speaking at the district convention at Springfield, said that the shortage of coal next winter would be more keenly felt than last winter, and that it was the duty of the miners to work every day so as to mitigate the famine which is sure to come. "Five million men will soon be fighting in France under the American flag," he said. "Many of these will never come back. Many will return crippled for life. How can a man who has not done his full share associate with the men who have given so much for their country? Can a man who refuses to do an honest day's work look these men in the face?"

The Springfield district convention adopted a resolution imposing a fine of $25 upon any miner who fails to drive a 12-ft. room neck a full 12 ft. wide. It was decided to lodge a protest with state mining officials against the high prices now being paid by miners for blasting fuses. It is said that though the fuse is expensive it is nevertheless faulty and dangerous. The state officials will be requested to take the matter up with the National Government.

In Illinois Union Backs Minerettes

Chivalry and patriotism are being invoked by 600 miners employed by the Chicago, Wilmington & Franklin Coal Co. at Thayer, Ill., to justify a strike which has continued two weeks and which officers of the United Mine Workers of America have been unable to settle. The demand of the men is that a woman with two children, whose husband has gone into the army, shall be given the job of the weighman at the mine, William Shutt, who was called to the colors two weeks ago.

When Shutt went away the war widow, who lives at Virden, was an applicant for the vacancy, and the miners favored her application. But the company employed Frank

Riva. The top men immediately filed an objection and were backed up by the diggers. Demand was made upon the company for the removal of Riva and the appointment of the woman. The company refused to give her the place and the men quit work. In the two weeks since they threw down their tools they have worked only 10 hours.

On Friday of the first week of the shutdown state officials of the union visited Thayer and prevailed upon the men to return to work. They worked five hours that day and five hours the next day, which was the day of election of union officials, and for this reason was a short working day. By Monday morning the effect of the officials' arguments had evaporated, and the men have continued to absent themselves from the mine. A Canadian army recruiting officer who happened to be in the neighborhood tried his hand as a peacemaker, but had no success. Pressure has been brought to bear upon Riva to resign, but he refuses. He is said to have been threatened. Many of the miners, pending a settlement of the dispute, have been helping in the harvest fields.

Missouri Miners Make Demands

Missouri is not much of a coal-mining state. The coal mines of that commonwealth are farther away from the river towns of Missouri than are the mines of Illinois. As the river towns include St. Louis, it is easy to see how sadly the Missouri mines are left in the cold. The refineries of the eastern part of the state are far closer to Illinois mines than to Missouri mines, and the Joplin lead and zinc district is almost equally remote from both Missouri and Illinois fields. However, Kansas City and St. Joseph are notably nearer the Missouri fields than those of the rival state.

The Missouri mines thus have a considerable handicap, which might not be decisive if the coal were purer and thicker. Unfortunately, the seams are quite usually thin and not exceptionally clean. As a result the mining field of Missouri has not been a regular and important producer.

The mine workers in the Fulton district, Callaway County, are demanding such large increases in wages that the operators are unable to pay the increase unless they can increase the selling price. This they are unable to do without Government permission. They are quite willing to have the Government take over the mines if it can be induced to do so. The miners are now getting $1.62½ a ton (6½c. a bushel) for open rooms and $1.87½ a ton (7½c. a bushel) for corner rooms. They demand $2 and $2.25 a ton (8c. and 9c. a bushel) respectively. For day work the mine workers are getting $3.25 a day. They demand $4.50. For room turning they want an increase from $7 to $10, and an extra payment in rooms where it takes two men to push out cars. The operators will have a meeting in a few days with County Fuel Administrator Harry Atkinson, who adjusted the wage controversy last year. There are eight mines in the district.

Judging by the comparatively low day wages, the digging of coal in the Fulton district mines must be accompanied with many difficulties or otherwise the miners would make many times as large a wage as the day men.

New Light on Production Problem

One can trust the union to look upon the production problem from a different angle to the operator, but it is well to see the union point of view. It is apt to be not entirely unjustified. While urging the mine workers to work on the Fourth of July, work being the best kind of patriotic demonstration, President J. R. Kennamer and Secretary J. L. Clemo are sending to every local union a questionnaire.

The first question is one which an operator might ask: "How many days or hours were lost during the week on account of miners lying idle?" After this come a lot of questions which show that there are joints in the armor of the coal operator. He might well be asked to consider them. Bunching the questions together they run: "How many days or hours were lost during the week; (2) on account of miners having no timber for their places? (3) on account of bad air? (4) on account of water? (5) for lack of switches or track? (6) on account of the coal not having been cut in time for the loader by machine cutters? (7) from lack of railroad cars? (8) by reason of the necessity for handling coal two or three times before loading? and (9) by waiting for mine cars to be placed?"

Other questions inquire: "How many men were sent home every day in the week on account of grievances with officials of the company? What is the average car turn per miner per day? How many cars could be loaded per day by each miner if the company would keep a square turn and supply an ample number of cars?"

There are two sides to the mine-car question. Give the miners all the cars they can load as soon as they can load them and they will load what they want of them and go home. Consequently, there is no disposition to create "rush-hour" conditions by excessive equipment of cars, mules, locomotives and what not, nor by the employment of large numbers of drivers and motormen so that the work of the day can be done in the early part of the morning.

If the men would work hard for eight hours a day, the operator would be repaid in buying enough cars and equipment to give every man a turn equal to his utmost capacity. But they will not do so, and when an operator has sufficient equipment to bring out in a full day what the men are willing to load he is not disposed to buy more. The length of day having been shortened in Alabama, and equipment being exceedingly expensive and hard to obtain, the probabilities are that the equipment supply is somewhat inadequate. In fact, at most mines if the men show a disposition to do their utmost the equipment, which is only attuned to ordinary industrial effort, fails to respond to the great demands made on it.

How They Do It in Pascagoula, Miss.—The shopworkers of Pascagoula, Miss., give one day's pay for four months in aid of the Red Cross. Edmon J. Lane, chairman of the Red Cross Fund, says to Chairman Hurley, of the United States Shipping Board, in a telegram, "They are the finest bunch of generous, patriotic, true American citizens a community ever boasted and we are proud of them. These same shipworkers were responsible for our county making five times oversubscription on third Liberty bonds.

Must Seek Unskilled Labor from Government—The United States Employment Service has now been greatly developed and separated from the Immigration Service. After Aug. 1 the Employment Service will be the authorized medium through which to obtain unskilled labor, though men applying for work at a plant may be engaged. On June 17 the President solemnly urged "all employers engaged in war to refrain after Aug. 1, 1918 from recruiting unskilled labor in any manner except through this central agency."

Employes of Two Companies Get Favorable Wage Decision—On June 17 Charles P. Neil, the umpire of the conciliation board decided in favor of the men at the Clinton colliery of the Delaware & Hudson Co., awarding them an increase in their wage of 7 per cent. instead of the 3 per cent. that had been paid them under the company's interpretation of the last contract. The footmen at the Packer No. 3 colliery of the Lehigh Valley Coal Co., near Shenandoah, also received a favorable verdict, men receiving 27c. per hour being awarded 32c. by the umpire.

Mining Pays a Young Man Far Better Than Teaching—School teachers and high-school graduates are recorded to be entering the mines in Harrison County, West Virginia, which forms the southern half of the Fairmont field centering around Clarksburg. A score of teachers are already at work in the Fairmont district. Some of the younger men have been compelled to enter the mines by the pressure of the regulations against idleness, both Federal and local. The wages earned are large now that work is reasonably steady. One Syrian miner made $148.39 in two weeks, yet there was one day of lost time in that period. Many miners are making from $126 to $140 every two weeks.

EDITORIALS

Foreigners Expect Hardships; Why Not Disappoint Them?

THE laboring man of Europe comes here from a picturesque little village. It may not be sanitary, nor comfortable, nor commodious, but it is almost sure to be pretty and homelike. The men who come to our mines from foreign countries are mostly farmers, not miners or city dwellers. Their homes are embowered in the verdure of trees and gardens, with many a quaint and artistic adornment.

They come here to make money, and make it quick, and go home. They do not worry much about where they live or where they work. They are quite generally not intending to become naturalized when they arrive in America. Citizenship is quite rarely what these farmers expect to seek when they come here.

What do we do with them? We fall in with their ideas. We give them a chance to make money, lots of it. We house them as they are quite willing for a time to be housed. But home was never like this, and eventually they go back to the pretty home they left.

They take a lot of American ways with them. They wear American clothes and show by their new modes of life and democratic self-recognition that America has left its impress on them. They cause more foreigners to try their fortunes in America. These come, not intending to stay, though many ultimately make it their home. Perhaps we work out our destiny in this way as well as if we kept every foreigner who entered our ports. These homegoers send us recruits; they preach our gospel of equality, and they start weaving kindly fairy tales about us, as people quite generally do about the lands where they spent their earlier years.

But if we really want to keep them, naturalize them and rivet them to the soil, we must give them comfortable homes and beautiful surroundings and not merely such a house as they will accept as their temporary barracks.

They are like us. They like beauty just as much as we do, though most of them are not voluble in the expression of it, and many not overcareful in its preservation. Art in all its many forms is at least as indigenous to Europe as it is here. The people of Europe are more imaginative and impressionable than we are. Yet we think they will call a barracks home, and living in a squalid village will learn to become magniloquent about America. We all know it can't be done.

The America they know is the America they live in. The nation they know is not the nation expressed in ideals, but the nation expressed in the living conditions with which their lives are environed. The foreigner has no reason to complain. He came for money and he gets it. But though this is true, it is equally true that too often he has no reason to stay when the money is made. He wishes to spend his last days in a smiling environment, so he goes where nature smiles, and where he has friends who welcome him. He can hardly be blamed. He leaves without rancor, but he leaves nevertheless.

Do we want to hold him here? If we do, we must let him see something in America that will appeal to his inner temperament. He is more apt to talk about money than anything else, but is there nothing else he thinks about? Most of us find it hard to express the finer motives that actuate our lives. How much harder it is for the man who, not speaking our language, lacks even the vehicle of that expression.

Fair and Unfair Taxation

THE PUBLIC is being brought by Congress to favor reasonable principles in its treatment of war industries. The disposition of Congress is not to single out for taxation the profits of war industries, but to put the burden on all excess profit from whatsoever industry obtained. A jeweler or platinum jobber who makes a large profit by keeping platinum on hand while the price soars is just as much entitled, and in fact far more entitled to pay a tax than the manufacturer who is making something in platinum that will serve our war interests.

The reply is, of course, that the manufacturer of useless things is going to be put out of business or restricted in his operations—after a while. Meantime he is allowed to go on his way almost unmolested, and there is a disposition with some to subject him to a taxation lighter than that put upon the man on whom the burden of war preparation falls.

We have recognized by our large pay to shipworkers the necessity and even the justice of allowing a generous reward to those who give up their regular occupations and tear themselves from their homes to engage in a war industry. We acknowledge that without this reward men would go on working at their old jobs around their own homes. The change to a new job in a new town involves expense and risk for which we are willing to pay them, for which, indeed, we must pay them, unless conscription of labor is to be resorted to.

Sometimes we cannot see that capital is equally entitled with labor to be rewarded for effectual service in war industry. But if we can not apply to capital what we apply to labor, we may, at least, concede that it is entitled not to be penalized for its support of the war.

The Federal Trade Commission has been investigating the production of essentials and found that some persons are making big profits in the manufacture of war necessities. It must be remembered that the Commission did not inquire into the production of nonessentials, but if it had it would have found that large profits were made in this work also. The natural result is to direct the public indignation against the industries thus exposed and leave the others, the less honorable businesses, free of censure.

It is like the attitude we take to the idler. Never having worked, we accept his idleness as a natural condition; but of the worker we demand that he shall come to work at the hour and for the time designated. We have learned to rely on him, and we turn on him uncompromisingly when he shows a disposition to be as undependable as the idler. It was as a reaction to this report that the war-industries tax was advocated. Reflection shows that the worker industries should, at least, have equal treatment with idler industries and pay no larger proportion of their receipts to the state.

A straight excess-profits tax applicable to all industries, essential and nonessential, does not penalize the manufacturer of war-worthy materials, nor does an income tax. Of all imposts, the income tax is the most equitable, while a tax on the income from luxuries is the most directly effective in putting us on a war basis. No one has ever been able to bring any other reasonable charge against the imposition of an income tax except its ease of evasion, and it would seem that with the freedom with which the Federal Government now investigates all business it should be easily possible to check all statements of income so as to remove the solitary objection to providing an extension to this form of impost.

However, it must be remembered that even the income tax makes no allowance for depletions of capital. All losses must be borne by the individual without relief from taxation. He does not pay on the real increment of his fortune, but on the increment only of his profitable investments. If the gain on the latter is not far greater than the loss on the others, he will inevitably lose heavily should the income-tax rate be made prohibitively high.

Standardization of Mine Statistics

UNDER THIS title the Bureau of Mines has published a bulletin of forms for the gathering of mine statistics. The tables were prepared with the purpose of reducing the complications resulting from the division of authority between the Bureau of Mines, the state inspectional forces and the state workmen's compensation boards. All these various authorities desired reports on accidents and equipment.

All were apt to view the matter from a slightly different angle, and that fact made the collection of data laborious for the state and Federal authorities and even more trying for the owner and his agents at the mines. Albert H. Fay's knowledge of the industry and of the science of statistics and the recognized ability of the members associated with him in the committee on standard forms appeared likely to assure us that the task to which they applied themselves would be carefully and adequately performed. Unfortunately, the upshot was that the excellent forms prepared by Mr. Fay for accident statistics were considerably modified, not at all for the better.

It appears from the "First Report of Injury to Employee" that the superintendent or manager of the mine is asked to state of all accidents whether they occurred in the mine or on surface and also what were the mining methods in use. It would be interesting to know more than this; for instance, whether the accident occurred at the face, in some part of the room away from the face, or in the entry, or slope. Mr. Fay has been collecting that information and surely he has been fully justified. We might reasonably desire to have the form ask what the person injured was doing or presumably doing at the time of his death or injury—undercutting by hand or by compressed air or electric machine, timbering, loading, brushing, walking or resting—for accidents from falls of roof have a direct relation to the kind of work being performed. Thirdly, it would be interesting to know whether the operation was on the advance or in the skipping or the drawing of pillars, or again in longwall. For some reasons, which we cannot divine but which are possibly more or less imperative, many of the matters so interesting and suggestive in both the Pennsylvania and Illinois reports and in the reports prepared by Mr. Fay are omitted in the schedule that the committee on standard forms now presents.

In the name of mercy we have wished that the example of Great Britain might have been followed and some record have been kept of the fatalities of the mining stock. The industry is unfortunately not any too kind to the mine mule. These poor animals are allowed to stumble along in a dark mine without a light, with cars on the road and all kinds of bad traveling conditions, including open ditches and slippery planks, stepping over high ties on a run and lifting their feet with difficulty out of morasses of mud. Their treatment is none too creditable to the hearts of their masters, and something should be done to make their woes and ill treatment a matter of record, especially as many of their accidents jeopardize not only their own lives but the lives of their drivers and of passers by in the narrow and winding mine roadways.

As for the table on power-plant equipment given in the bulletin, the classification of boilers into cylindrical and tubular is insufficiently complete and seems a relic of earlier conditions and older statistical tables. If we cannot have names of boilers and must be general in our listings, and such generalizations have their advantages, let us list the boilers as flueless, nontubular boilers, fire-tube boilers, water-tube boilers and then let us have some divisions based on the method of firing—by hand, by automatic stoker, or with powdered fuel. It would be well also to obtain some information regarding the use of ropes for haulage. It seems incongruous to ask about the number of horses and mules engaged and to inquire about the number of locomotives of four principal types—gasoline, steam, compressed-air and electric—and then ask no questions as to the number of hoists in shafts, entry and room haulage. Furthermore, the trolley locomotive should be differentiated from the storage-battery locomotive, the reel locomotive and the combined battery-and-trolley locomotive.

The cylindrical boiler, or flueless nontubular boiler, is an obsolete type. Bold and enterprising explorers in the anthracite region, it is said, can surprise such rare birds in covey, when the game wardens are not watching, but we understand that in no other coal regions have these early fuel wasters been able to resist the progress of industry and perpetuate their existence. In justice to the anthracite region, it must be admitted that the cylindrical boilers are only stand-bys to be used in emergencies when floods make the draft on the standard colliery equipment more than usually heavy.

DEPARTMENT OF HUMAN INTEREST

Kansas Has School for Mine Workers

Night courses, especially adapted to the needs of bituminous coal mine workers in the Pittsburg (Kan.) coal fields, have during the past fall and winter brought to these men a technical knowledge of mining methods which will, it is hoped, result in the greatest output of coal with the least waste of life, machinery and effort.

These courses have been given in classes of from 25 to 50 men to a class in various cities and towns throughout this field. The instruction has been given by Prof. J. A. Yates, head of the Department of Physical Sciences, and Prof. J. A. G. Shirk, head of the Department of Mathematics of the Kansas State Manual Training Normal School at Pittsburg.

The courses have been arranged so as to give the mine worker just the instruction necessary to more fully develop the art of scientific mining. Many of the men are miners of long experience, yet they have performed their work with little understanding of the principles of scientific mining, which include the study of gases, the causes of spontaneous combustion, ventilation, the causes of explosions, haulage, the analysis of air, humidity and various other subjects of real value in lessening the probability of explosions with their consequent loss of life.

This instruction has been given by Professor Yates, who met his classes at stated times in the various towns in the vicinity of Pittsburg, where large mines and strip pits are located. The courses are not exclusively limited to actual coal mining, but include a thorough study of machinery in and around the mine, comprising steam engineering in all its branches, fuel economy, draft control, boiler construction, safety appliances, lubricants, cable tests, safety catches, signals, valve setting and other important phases of efficient engineering. Professor Shirk gave this instruction, meeting his classes each week.

When the present war made imperative the greatest possible production in all lines of industry, President W. A. Brandenburg, of the Kansas State Manual Training Normal, determined that the school should be made of the greatest possible value to the nation in the crisis. He felt this could best be done by giving laboring men a scientific knowledge of their work. Being located in the heart of a large coal field, it was at once evident that this object could in no way be better accomplished than by offering special courses for miners, stationary engineers and firemen, thus enabling them to maintain a maximum production of coal with the least waste.

In consequence of this determination the following cities and towns in the coal field were visited and miners' night classes organized: Mulberry, Arma, Ringo and Scammon. The school being centrally located offered an excellent place for such classes, and many miners and engineers have evinced much interest in the movement. In consequence of the training the Kansas field is becoming a greater asset to the nation at war. Professor Yates' courses are planned to develop a habit of coördinating the work of brain and hand, thereby improving working conditions in the mine, insuring better health to the miners, and making the miner's lot a happier one. The courses also give information which if utilized will reduce the number of accidents in the mines.

Miners and engineers of many nationalities and of varying ages have enrolled in these courses. After a day spent in the mines at laborious work, it is no small effort for these men to spend an evening in study, but so eager are they to become of the greatest value to the nation in this present war crisis that attendance during the term now drawing to a close has caused President Brandenburg, Professor Yates, and Professor Shirk to plan already for a still greater, wider and successful effort in this line during the coming school year.

A CLASS OF MINE WORKERS AT RINGO, KANS., WHO ARE STUDYING THE MYSTERIES OF THEIR EMPLOYMENT
They believe that the art of mining needs study as much as the art of farming or of any other industry

Contributed 508 Tons in One Month to Beat the Hun

An Ohio Miner of American Birth loads 508 Tons of Entry Coal in Month of May

In 22 Working Days of 8 Hours. Coal only 3 feet 8 inches high and Entry 15 feet wide.

Ed Blagg, a loader in No. 1 mine of the Buckeye Coal and Railway Co., San Toy, Ohio, averaged 23 tons per day during the whole month of May, working every day he had a chance. This is about 3 tons for every working hour or one ton every 20 minutes.

Blagg is of draft age, and he is ready any time to be called; meanwhile he intends to help in the war by mining all the coal he can. He is 27 years old, married and has one child. He is of American ancestry, being born and raised near Ironton, Ohio. He has contributed liberally to the Red Cross and Y. M. C. A. and bought $100 of War Savings Stamps.

Joe Swagda is his nearest rival. He loaded 462 tons in May and has subscribed liberally to all war activities. The miners of San Toy have already bought $21,000 worth of War Savings Stamps.

Discussion by Readers

Carbide vs. Electric Mine Lamps

Letter No. 1—I have read with interest the article "Electric Lamps in Nongaseous Mines," *Coal Age*, Feb. 2, p. 239, by George H. Deike. As this article has evidently been prepared and submitted in the interest of electric mine lamps, in disparagement of the popular carbide lamps, I am led to offer a few comments in justification of what I claim is an ideal lamp for use in nongaseous mines.

In the first place, would not the ordinary precaution of testing for gas by a protected safety lamp of an approved type have prevented the gas explosions mentioned as occurring in the Cleveland water tunnel, the Michigan copper mine and the salt workings near Ithaca, N. Y.? If, as Mr. Deike states, the presence of gas may be looked for in such operations, it would appear readily possible to detect it and guard against such accidents by an ordinary fireboss test with any approved safety lamp.

Of the eleven points of advantage claimed by Mr. Deike for the electric lamp, with the exception of the first two, every one may be claimed for the carbide lamp with equal or even greater force. As an offset to those two, may be set forth the detection by the flame of the carbide lamp of an atmosphere deficient in oxygen content, which is obviously impossible with the electric bulb; and fatalities due to this cause have not been unknown.

Advantage and Safety of the Carbide Lamp

With regard to fires caused by open lights, Mr. Deike has failed to differentiate between the carbide flame, with its tiny pencil of burning gas, and the old-fashioned oil torch, with its large wavering flame, falling sparks and burning wicking. Tests made by one of the largest anthracite companies some years ago on what may be termed the relative "zone of inflammability," as between oil and carbide lamps, thoroughly established the great difference between them, and caused the recommendation of the latter as an eminently safe illuminant, with reference to fire risk.

Referring to the extinction of lamps by air currents, Mr. Deike is possibly not aware that the development of the art has produced an attachment for carbide lamps, which will hold the flame in the strongest air current met with under working conditions. Relighting devices have also been perfected that make the relighting of the lamp very simple and quickly accomplished.

A similar criticism may be made of Mr. Deike's conclusion regarding the time lost in adjustment and regulation of lamps. While his statement may be correct as to conditions of a few years ago, improvement in manufacture has now reached a point where the carbide lamp is practically self-regulating; and, with ordinary care, may be depended on to give a satisfactory working light, with little or no adjustment.

On the question of operating cost, Mr. Deike's figures are not altogether convincing. He has complacently pigeon-holed the two interesting items of first cost and depreciation; and has assumed a minimum figure for carbide (again classing it with oil) of from 6 to 7c. per shift. I can offer as against this an actual cost for carbide of 2½c. per eight-hour shift, based on figures submitted to me by a leading anthracite company.

In conclusion, let me say that I have no desire to urge the use of carbide lamps in any mine where there is the slightest doubt of their safety. It has been my practice for years, in cases of this kind, to recommend the use of electric and safety lamps, but in reading Mr. Deike's article I feel that he has done scant justice to the real merits of the carbide lamp, in its own particular and well-recognized field; and I wish definitely to enter my protest to some of his conclusions.

Scranton, Penn. Francis H. Coffin.

Surveying and Mapping

Letter No. 7—In discussing this subject in *Coal Age*, not long since, little or no mention was made in respect to the character of mine maps. The mine map is the chief and generally the only means of recording the information relating to the shape, extent and condition of the workings underground. Notwithstanding this fact, it is too often neglected.

Most states require that an accurate survey shall be made and platted to a given scale, at stated times, so as to insure a complete record of the excavations made beneath the surface being always available for future reference. Such a record has often proved of the utmost importance, both in respect to surface damages that sometimes ensue, and as affording an accurate knowledge of the proximity of old and abandoned workings, in the development of adjoining properties.

The Complete Mine Map

For completeness of information, the mine map should show fully the surface plant and should include the boundary lines of all properties owned or leased by the company, the location of such physical features as lakes and water courses, together with all surface improvemnts, such as railroads, highways and buildings. The surface plant should be laid out in detail and show the tipple and various buildings, supply yards, reservoirs, pipe lines and drains, together with the location of the mine openings and the outcrop, if any, of the coal.

The underground workings or mine plan may be drawn on a separate sheet; but this is frequently combined and drawn on the same sheet with the surface plan, which enables a closer inspection and reference to be made in determining the relation of the underground workings to the surface features. The under-

ground plan is a projection on a horizontal plane. The plan should show the mine openings, shafts, slopes or drifts, and all airways, roads and passageways in the mine, together with all pumprooms, enginerooms, stables, tool shanties and other openings driven in the seam, besides the many working places in the mine.

The plan should also show the location of all faults and other disturbances or irregularities of the seam, together with information regarding the dip or pitch of the seam, thickness of the coal and the advance of the working face from year to year, as determined by each successive survey. The position of all drillholes should be marked on the map together with the depth of the hole, or the elevation of the seam at that point, and the thickness of the coal. This will enable the work of development to be carried forward intelligently.

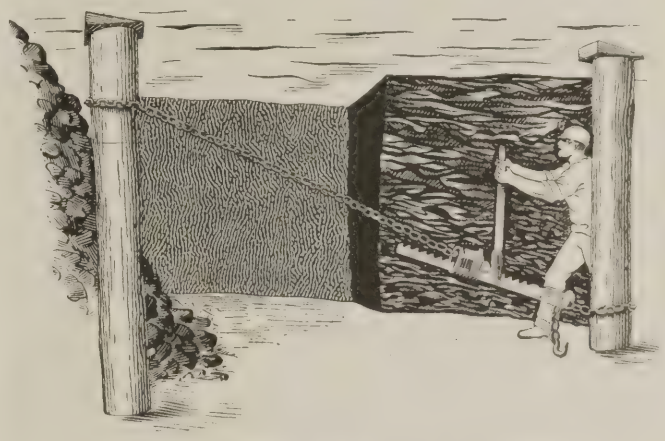
Additional Information on Mine Maps

In addition to the surface and underground plans, there are often required longitudinal and transverse sections. The former may be either a vertical section or one lying in the plane of the dip. The latter is usually platted on a plane at right angles to the former. Certain geological data relating to the changes of dip and strike are important in the future development of the mine, particularly when contiguous seams are worked at the same time or through the same opening. All plans should be made, as far as practicable, on the same scale, which will facilitate their reading. The ground plan should show fully the direction of the ventilating current. Complete mine plans are of the greatest importance in case of an explosion or other mine disaster.

In the case of a mine explosion or serious disaster, many of the rescuers who flock to the mine to offer their aid are wholly unacquainted with the underground workings and the ventilation of the mine. It is on such occasions that the need of an accurate map showing all the underground features, including the ventilating current, doors, stoppings, air bridges, etc., is absolutely essential in order to cope efficiently with the disaster. All mine maps should be dated and signed by the engineer or surveyor who took and plotted the notes and who is responsible for their correctness.

Golden, Colo. Fred L. Services.

Pillar Workings



Letter No. 1—Like many other mine officials confronted with the problem of safe pillar drawing, I have given much attention to this feature of coal mining. The numerous references made to this class of work, in *Coal Age*, and particularly the letter of W. H. Noone, which appeared in last week's issue, June 29, p. 1210, tempt me to give a few of my own impressions regarding the recovery of timber in pillar workings.

The records for the year 1915 show 934 fatalities inside the mines of Pennsylvania. Of these 527 occurred in the anthracite and 407 in the bituminous region. Of the 407 lives lost in bituminous mines, 78 were due to falls in pillar workings, which is a large percentage considering the comparatively small number of men employed in that work. In his classification of mine accidents, Mr. Noone makes no direct mention of those that occur in the drawing back of pillars, although he probably includes these under the head of "falls of rock and coal."

Recovering timber by hand with the aid of an ax or sledge is dangerous work, in spite of every precaution that may be taken by experienced men. It seems strange that with the adoption of mechanical appliances, in practically every branch of mining work, the custom still prevails of knocking out posts with a hammer or ax and taking the chance of being caught under the fall of roof that is liable to follow.

As a safety measure in the drawing of timber, a mine official is often instructed to supervise the work, although it is generally the case that the men in his charge are as practical as himself. For this reason, the measure adopted can hardly be considered as a safety measure. A real safety measure would be the adoption of a mechanical post puller that would enable the men performing the work to stand beyond the danger zone while thus engaged.

One of the most practical devices of this nature is the Sylvester device, sometimes called the "Sylat post puller." The accompanying figure illustrates the practical use of this device, in the drawing of timber in

DRAWING TIMBER IN PILLAR WORKINGS

pillar workings. By its use, the man performing the work is protected against any possible fall of roof, and accident from this cause is avoided.

It is a theory of mine that a number of roof falls occur, particularly in pillar workings where there is apparently no actuating cause, and that these may be due to a vibration set up by a vibrating sound that is properly attuned. The boulder that falls from the roof may be large and weigh, say 100 tons and yet have been so balanced that it required but a vibration to throw it out of poise.

The singing of a man with a powerful voice has been known to break a fragile vase. The same singer, by the vibration set up by his voice, caused a glass of water to spill. It seems to me that it is not impossible that such innocent causes may act to produce a fall of roof in the mine, in certain instances.

In pillar workings, when the coal has been taken out, the roof naturally rests on the timbers and is often in a balanced condition that requires but a slight cause to make it fall. There are many vibrating causes occurring in the working of a mine, and this condition alone emphasizes the need of adopting a device or method that would place the workmen out of harm's way when drawing timber.

In studying over this question, under varying conditions, it has occurred to me that when the pillars are mined with a shortwall machine it is possible to make use of the feed-line of that machine for drawing timber. The feed-line is of ample strength to withstand a hard pull, as it is ⅜ in. in diameter. Also, since it is generally 40 ft. long, there will be no difficulty in reaching any timbers that it is desired to pull and still keep the machine in a safe place.

After fastening the line to the timber to be drawn, the machine could be moved back along the track, by its own propelling power, and this will generally result in pulling out the timber. However, should the timber resist the movement of the machine and cause the wheels to slip on the rails, it is possible to brace the machine and apply the power to the feed-drum. But this will only happen when the timber is so banked with slate as to give it greater resistance to the pull. It often happens that when a post is knocked out by hand it is covered up and lost by the fall. This cannot occur ordinarily when the post is drawn by any mechanical device such as I have described.

———, Penn. ROBERT LITTLEHALES.

Mine-Rescue Work

Letter No. 1—When is a man brave and when is he foolhardy in the face of danger, and what is the dividing line; or is that a matter of individual judgment? I am led to ask these questions after reading the incident cited at the close of Fred B. Hicks' letter on "First Aid to the Uninjured," *Coal Age*, June 1, p. 1029, when 13 men lost their lives in a fruitless attempt to recover the bodies of two of their comrades killed by an explosion in the mine workings.

We have had, in the history of mining, many sad catastrophes and, no doubt, will have more in the future; but the saddest of all is the fate of many heroic rescuers who sometimes, without precaution, rush to the aid of their less fortunate fellow workers.

Lessons Taught by Previous Mine Disasters

Speaking for myself, the lesson of taking many precautions in attempting rescue work was learned at the terrible Harwick mine disaster, which occurred at Cheswick, Penn., Jan. 25, 1904, and resulted in the loss of 178 lives. Immediately following that explosion the mine fan was repaired and an exploring party went down in a hoisting bucket, as the cages had been blown out of the shaft by the force of the blast. The rescuers followed the air into the mine, but in their eagerness to reach any men who might have survived the explosion, they failed to notice one place where the air was short-circuited. As a result, the leader of the party, who was my first engineering employer, lost his life in the afterdamp into which they plunged.

Who that is interested in coal mining fails to recall the sad result of the brave attempts made to rescue the unfortunate men trapped in the Cherry mine, in Illinois, when a fire occurred in that mine, at noon, Nov. 13, 1909, and 259 lives were sacrificed as a result? Volunteering for rescue work, a party of trained, professional men, and miners who worked on the night shift, were lowered to the first level and succeeded in saving many half-suffocated miners.

Before long, however, the shaft bottom became untenable by reason of the great heat and the rescuers were forced to get on the cage to be hoisted to the surface. My information is that, through a misunderstanding in the signals given, the cage was hoisted but a few feet above the bottom, where the men were burned to death.

At the Port Royal disaster of June 10, 1901, Port Royal, Penn., a party of 15 rescuers lost their lives in a venturesome and vain attempt to recover the bodies of four men who had been sent into the mine that night to do some bratticing. The men continued to advance, notwithstanding they had been warned of the conditions existing at the place by others who had attempted the rescue and were forced to return.

Origin of the "Safety First" Slogan

Most of our large mine disasters might have been prevented had their methods of operating been changed and certain precautionary measures employed. I recall a terrible explosion that occurred in the early nineties, whereby one of the largest coal-producing companies in the country learned a lesson that resulted in the adoption of the slogan "Safety the first consideration." Safety rules and regulations were posted and enforced in all their plants.

The company operated scores of the deepest and most gaseous mines in the bituminous coal fields, and were pioneers in the great safety-first campaign that followed. The record of that company since is absolutely clean and free from disasters, and the rules and methods they adopted at that time are the foundation of our present state and insurance regulations.

Rescuers Lose Lives in Recent Disasters

At Villa, W. Va., May 20, this year, a fire occurred in the mine of the Mill Creek Cannel Coal Co., costing the lives of 14 men. In the attempt to rescue the men entrapped in the mine, seven of the rescuers were overcome by the fumes and gases of the fire and were, with difficulty, resuscitated. An item regarding this fire appears in *Coal Age*, June 1, p. 1033, and a fuller account of the disaster is given in the same journal, June 15, p. 1106.

Only a few days ago, a series of terrific explosions extending over a period of five hours ruined a high-explosive manufacturing plant a mile and a half from here and caused a death list of between 100 and 200 men, many of whom were rescuers. Three of our men living in that vicinity assisted in the work of rescue.

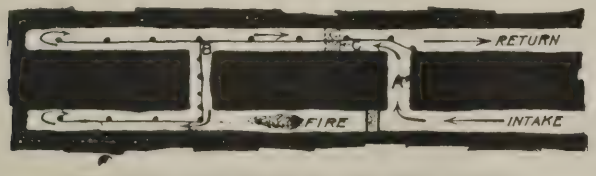
Hurrying to the scene, I assisted in removing possibly 30 badly maimed and injured men to the nearest physicians. The plant lay in a deep valley and covered about 15 acres. In our work we were partially protected by a projecting spur of the hills from the force of following explosions, which killed many of the rescuers who were less fortunate.

While thus engaged, two terrific explosions occurred about 10 min. apart, throwing flaming acids hundreds of feet into the air. Having finished our work in that vicinity and being informed that there were thousands of pounds of the highest known explosives that would shortly be reached by the fire, we left the place and an hour later this last heavy explosion occurred, killing many rescuers, among whom was one of our

own employees who had volunteered but two minutes before the blast occurred.

Miners, as a class, are noted for their bravery in the face of danger and are often assigned to the most important work on such occasions. It frequently happens that the best judgment of rescuers is biased by the wails of women and children whose loved ones are in danger. To enter a mine ahead of the air is nearly always fatal, as a second explosion may often occur when fresh air is forced into the workings and mixes with the accumulations of heated gases, or forces fresh gases over a fire smoldering in the debris.

While breathing apparatus can often be employed with advantage when exploring a mine ahead of the air, or in fighting mine fires, it is generally the case that where the mine air is sufficiently foul to require the use of breathing apparatus it is too foul to support life, and there is little hope of rescuing men by this means.



Artificial resuscitating appliances also have their uses. If I am correctly informed, however, a number of deaths have occurred within the last few years from respiratory diseases, after such resuscitation. While we should always desire brave men for rescue work, they must not be foolhardy, but take every precaution to avoid unnecessary danger. J. S. GELSTON.

Noblestown, Penn.

Sealing Off Fire on Intake

Letter No. 1—Permit me to refer to the inquiry of "Ancora," *Coal Age*, June 22, p. 1173, regarding the sealing off of a fire on the intake side of a pair of headings. The inquiry assumes there are no rooms on these headings and that only a small quantity of gas is generated, making safety lamps unnecessary, and asks for the proper order of building stoppings to seal off the fire.

The danger encountered in performing this work arises from three causes: (1) The formation of an explosive mixture of marsh gas and air at the face

STOPPING OFF FIRE ON INTAKE AIRWAY

of the heading. (2) The generation of carbon monoxide in the region of the fire when the supply of air has been limited or cut off by the building of a stopping. (3) The ill-effects experienced by the workmen in the return airway, due to the gases generated by the fire.

In discussing this question, let me say that my experience has taught me that there is more danger to workmen required to work on the return airway after the supply of air to the fire has been partially cut off. The limited air supply results in the production of carbon monoxide, which is extremely poisonous.

I remember, on one occasion some years ago, that it was necessary to repair a couple of stoppings, which had been built to seal off a fire and were leaking. The men doing the work were quickly seized with violent headaches and palpitation of the heart. On another occasion, we were able to put out a fire that was not sealed off but had a plentiful supply of air and the workmen suffered no ill-effects from the gases generated.

BUILDING THE STOPPINGS

With this explanation, I want to outline my method of proceeding to seal off this fire. Referring to the accompanying figure, I would open up the stopping at *A* sufficiently to short-circuit a portion of the air, before starting to build the first stopping on the intake, which should be placed as near as practicable to the fire. At the same time, starting from the outby rib of that crosscut, on the return side, I would extend a line of brattice up the return airway toward the face. Carrying sufficient fresh air with me, I would extend this brattice through the inby crosscut at *B* and carry it up to the face of the intake heading, as shown in the figure.

If necessary, I would do the same on the return heading, so as to avoid any accumulation of gas at the faces of these headings. The smoke and gases from the fire would pass out on the return side of the brattice. In the meantime, the building of the stopping on the intake has proceeded. When that is finished all of the air will be short-circuited at *A* and carried by the brattice to the face of each heading.

The stopping on the return heading is now started at *C*. As work on this stopping progresses and nears completion, a portion of the air can be short-circuited at *A* and permitted to pass out of the mine on the return airway. It should not be difficult to build a stopping on the return with a canvas brattice running up the entry in the manner indicated. A piece of pipe should be built into each of these stoppings and provided with a valve or plug to permit the air to be tested, from time to time, to ascertain the progress made in the extinction of the fire. When building the brattice, frequent tests must be made of the air on the return side.

Thomas, W. Va. W. H. NOONE.

Interpreting Mining Laws

Letter No. 4—Referring to the interesting question raised by Charles Martin, *Coal Age*, June 8, p. 1080, I understand the meaning of the Pennsylvania Bituminous Mine Law to be that crosscuts, in room pillars, shall not exceed 35 yd. or be less than 16 yd. as stated in Art. 9, Sec. 3; while the same law, in Art. 6, Sec. 4, permits a distance of 200 ft. between crosscuts, in entry pillars.

Although the law does not so state, specifically, it is my opinion that the latter provision has reference to nongaseous mines only. Likewise, I believe that the longer distance of 35 yd., in room pillars, applies to nongaseous mines only, while a shorter distance, not less than 16 yd., refers to gaseous mines.

The specifying of shorter and longer distances, depending on the condition of the mine with respect to gas, makes possible a great saving in yardage on the entries, as well as the strengthening of the pillars in both rooms and entries, when the conditions permit the driving of crosscuts further apart as described by law.

It would seem to me that this is the proper interpretation of the law and that most practical mining men

would take this to be the intention of the law makers. The mine foreman is able to determine when the crosscuts can be driven at a greater distance and when this distance must be decreased in order to keep the face of the heading clear of gas, and this is left wholly to his judgment.

Referring to the question asking at what point the air current should be termed "return air," in the meaning of the law, Art. 9, sec. 1, reads, "The return air from each split where from 70 to 90 persons are employed shall be conducted by an overcast or an undercast into the return airway, which shall lead to the main outlet."

I take this to refer to the last crosscut in each split or section of the mine. From the mouth of the split, the air current is conducted through the workings on the intake airway and, on reaching the last crosscut, passes into the return. From this point until it reaches the overcast and is conducted by the main return airway out of the mine, the current is called the "return air."

In closing, permit me to say that 200 ft. is too far apart to drive crosscuts, without the use of a brattice to conduct the air to the face of the heading. Such a distance is too far for men to work ahead of the air. The brattice should extend to within 20 or 30 ft. of the face of the heading. These are important questions in mine ventilation, and I hope to see them fully discussed.

Worley, Ky. OSCAR JONES.

Letter No. 5—The recent discussion that followed the inquiry regarding the provisions of the Bituminous Mine Law of Pennsylvania, in respect to ventilation, which appeared in *Coal Age*, June 8, p. 1080, interested me greatly. This discussion showed the need of clearly understanding the meaning of the law, to do which one must read carefully the entire statute bearing on the points in question.

Referring to the question regarding the distance apart of driving breakthroughs in room and entry pillars, it is true that Art. 9, sec. 3, provides a maximum distance of 35 yd. and a minimum distance of 16 yd., in all room pillars, and makes no mention of entry pillars. In the same connection, attention was drawn to the reading of Art. 6, sec. 4, which states, "said entries shall be separated by pillars of coal of sufficient strength, and shall not be driven more than 200 ft. beyond the last cut-through, except for exploratory purposes."

Let us look, for a moment, however, at Art. 4, sec. 2, the second paragraph of which reads, in part, as follows: "He shall also see that proper cut-throughs are made in the pillars of all rooms and of all entries, in accordance with sec. 3 of Art. 9 of this act, and that they are closed when necessary so that the ventilating current can be conducted in sufficient quantity through the last cut-through to the face of each room and entry by means of check doors."

It is clear that the reading of this section makes the provision of Art. 9, sec. 3, to which we have just referred and which is here particularly mentioned, apply to both room and entry pillars, notwithstanding the fact that entry pillars are not mentioned in that section of the law.

In my opinion, the Bituminous Mine Law of Pennsylvania does not permit breakthroughs in entry pillars to be driven 200 ft. apart, except in the special instance to which reference is made in Art. 6, sec. 4. In order to understand this reference, it is necessary to read the entire section. In doing so, we find that this section refers to the driving of the main entries, from the first and second openings, in new, gaseous and nongaseous mines, providing further for mines opened as nongaseous but in which gas has appeared later.

LAW REGARDING MAIN ENTRIES

This section of the law provides for the driving of at least four main entries, two of which shall lead from the main opening and two from the second opening, into the body of the mine, in all mines generating gas in sufficient quantity to be detected by an approved safety lamp. In mines where locked safety lamps are used exclusively and a large acreage is to be developed, requiring a length of 5000 ft. or more on the main entry, this section prescribes the driving of at least five entries, two connecting with the main opening and two with the second opening, while the fifth entry is to be used as a travelingway.

The law is very specific and provides, likewise, in nongaseous mines, for at least two main entries, one leading from the main opening and the other from the second opening, into the body of the mine; except where a large acreage is to be developed, requiring a length of 5000 ft. or more on the main entries, in which case the law specifies that three such entries must be driven, one for use as a travelingway only.

Following this reference, the section states "Said entries shall be separated by pillars of coal of sufficient strength, and shall not be driven more than 200 ft. beyond the last cut-through, except for exploratory purposes." I understand this to refer to the thickness of coal that must be left as a barrier against a possible accumulation of gas or water beyond these headings, since the law provides (Art. 4, sec. 2) that no rooms shall be turned in advance of the last cut-through, thus insuring a solid pillar of coal beyond that point to the head of the main entries, except as the latter are extended for exploratory purposes.

WHAT CONSTITUTES A "RETURN AIRWAY"

The question of what constitutes a return airway should present no difficulty to the practical mining man. In regard to the gob section, mentioned in the inquiry to which I have referred, and lying between two live sections ventilated by a single current, such an arrangement would seem to be contrary to the reading of Art. 9, sec. 1, which requires the ventilation to be conducted through the entries and to all working places "in sufficient quantities to dilute, carry off and render harmless the smoke and dangerous gases generated therein, to such an extent that all working places and traveling roads shall be in a safe and healthy condition for the persons working and traveling therein."

It would not be possible to comply with the law were the ventilating current permitted to pass through a gob section and be then conducted into live workings. In such a case, the ventilation should be so arranged, by the building of an overcast, that the current after passing through the gob section would be conducted immediately into the return airway and pass out of the mine.

Leckrone, Penn. M. H. G.

INQUIRIES OF GENERAL INTEREST

Overcome on Reaching Fresh Air

An instance of men being overcome on their return to fresh air, after inhaling bad air in their working places for a considerable period, was brought to my attention sometime since. It has caused me much thoughtful reflection and I have often wondered if my conclusion in regard to the cause is correct. The facts as they were told me are as follows:

In a certain mine in this state, the men working in one section found the air in their places rather heavy one morning when starting for work. Owing to a door having been left open during the night, the ventilating current had been cut off from that section and the air was bad. Closing the door, the men proceeded to their work; but it was not long before they began to realize that something was wrong. There was a growing feeling of depression and all decided to quit work and go home, which they did without further delay.

Reaching the fresh air that was traveling on the main intake airway, the men were quickly overcome and fell unconscious in the entry. Here they laid for a short time when consciousness again returned and they were revived by breathing the pure air passing.

Studying over these facts as they were told to me, I concluded that the men were overcome by breathing a small percentage of carbon monoxide, which I assumed had accumulated in their working places. I understand that the symptoms resulting from carbon monoxide poisoning are somewhat as follows: tendency to dizziness, palpitation of the heart, shortness of breath, drowsiness, weakness of the limbs and final loss of consciousness. Later, conversation with the men convinced me that they had experienced all of these symptoms. Still, I am not confident that this is the real cause of the loss of consciousness when the men reached fresh air, and I shall appreciate being better informed on the matter.

Springfield, Ill. ASSISTANT SUPERINTENDENT.

There is no ground for supposing that the men, in this case, were overcome by breathing carbon monoxide. Had such been the case, they would have fallen unconscious in their places and not been able to reach fresh air. The occurrence may be explained as follows:

The cutting off of the circulation in that section of the mine, by the setting open of the door the night before, caused an accumulation of blackdamp in the working places. Shortly after starting to work, the men felt a dizziness and shortness of breath and very wisely decided to withdraw from the place.

Experiments have shown that there is an automatic regulation in the process of breathing air containing small percentages of carbon dioxide, whereby the percentage of this gas remaining in the lungs is maintained practically constant, averaging about 5.6 per cent. The breathing of air containing a greater proportion of this gas automatically causes a deeper inhalation followed by panting, due to the effort made to throw off the excess of gas from the lungs. The labored breathing causes palpitation of the heart and a rush of blood to the head, producing dizziness.

In this condition and with their lungs holding an excess of carbon dioxide, these men reached fresh air. But, the result of inhaling pure air when the lungs are partly filled with gas is to cause a temporary suspension of breathing and a state of coma or insensibility follows. The effect, however, is only temporary and in a short time the action of breathing is resumed.

This condition has often been observed upon bringing men who have been exposed to gas, to the surface. The victims will frequently lapse into unconsciousness in the cool, pure air, and this we assume was the case in the instance mentioned by this correspondent. Similar instances can probably be cited by readers of *Coal Age* in their varied experiences in coal mining.

Travel of Electric Current

Kindly explain the manner in which a current of electricity travels in a wire conductor. Does the current flow over the surface or through the wire; and, if both, does the same quantity pass through the wire as over its surface?

Benham, Ky. STUDENT.

This is a mooted question, in regard to which electricians have held different opinions. Formerly, many were led to believe that an electric current flowed over the surface of a conductor rather than through its body. We believe the prevailing opinion, at the present time, is that it is more probable that the entire body of the conductor is permeated with the current to a greater or less extent, but in what proportion it is impossible to state.

Referring to tables giving permissible capacities of wires of different diameters and of like material, as established by underwriters, it appears that the allowable current capacity of insulated wire conductors (which is an index of the heating of the wire by the passage of the current) varies as the square root of the cube of the diameter of the wire. For example, a wire having twice the diameter of another wire has a permissible current capacity of $\sqrt{2^3} = \sqrt{8} = 2.8$ times the capacity of the second wire.

While the connection between the size of a wire conductor and the heating caused by the current passing through it is not simple, the observed relation here expressed would seem to suggest that the mass of the wire is involved or concerned in the passage of the current. This relation does not appear to support the idea that the current flows over the surface of the conductor only.

Coal Age will be glad to have some of its readers who are expert electricians throw any new light on this subject that experimental investigation may afford.

EXAMINATION QUESTIONS

British Columbia Examination, First Class, May 14, 1918

(Selected Questions)

Ques.—Under what conditions may afterdamp become explosive?

Ans.—The afterdamp of a mine explosion may, and often does, contain unburned marsh gas, which becomes explosive on the addition of fresh air. The afterdamp may also contain sufficient quantities of carbon monoxide and fine dust floating in the air to render it explosive in the presence of fresh air. On this account great caution is needed when an exploring party enters the mine after an explosion has occurred therein.

Ques.—At the same temperature and pressure, which is the heavier, dry air or the same volume of air fully saturated with moisture?

Ans.—Air containing moisture is always lighter than dry air, bulk for bulk or volume for volume, because the density of the water vapor in the air is less than that of the air itself. The weight of water vapor is about five-eighths of that of the same volume of dry air, at the same temperature and pressure.

Ques.—With a barometric pressure of 30 in. and a temperature of 60 deg. F., (a) what effect would be produced on a given volume of air if the barometer should fall to 29.5 in.? (b) What change in temperature would be required to maintain a constant volume of air under this fall of barometer?

Ans.—(a) Assuming a constant temperature, a fall of barometer from 30 in. to 29.5 in. would cause an expansion in the volume of a given weight of air. In other words, for a constant temperature, the volume ratio is equal to the inverse pressure ratio. Hence, in this case, the ratio of increase in volume would be 30 : 29.5 = 1.017. That is to say, 1000 vol. of air at 30 in. barometer would be increased to 1017 vol. when the barometer falls to 29.5 in., temperature constant.

(b) In order to maintain a constant volume in a given weight of air, the absolute temperature of the air must vary as the barometric pressure. In other words, the absolute-temperature ratio must equal the barometric ratio, which gives, in this case, calling the required temperature x,

$$\frac{460 + x}{460 + 60} = \frac{29.5}{30}; \text{ or } \frac{460 + x}{520} = 0.983$$

$$x = 520 \times 0.983 - 460 = 51+ \text{ deg. F.}$$

That is to say, to maintain a constant volume in a given weight of air when the barometer drops from 30 in. to 29.5 in., the temperature must drop from 60 deg. to 51+ deg.

Ques.—If a certain pressure produces 20,000 cu.ft. of air per min., in an airway 6 ft. in diameter, what quantity of air will the same pressure produce in an airway 12 ft. in diameter, assuming the airways have equal lengths?

Ans.—In the ventilation of circular airways, for the same pressure, the volume of air in circulation varies as the square root of the fifth power of the diameter of the airway. In other words, the volume ratio is equal to the square root of the fifth power of the diameter ratio, which gives, in this case,

$$\frac{x}{20{,}000} = \sqrt{\left(\frac{12}{6}\right)^5} = \sqrt{2^5} = \sqrt{32} = 5.657$$

$$x = 20{,}000 \times 5.657 = 113{,}140 \textit{ cu.ft. per min.}$$

Ques.—The total rubbing surface of a square airway being 160,000 sq.ft., the length of the airway 5000 ft., and the quantity passing 80,000 cu.ft., find the velocity of the air current in feet per minute.

Ans.—The perimeter of this airway is 160,000 ÷ 5000 = 32 ft. Since the airway is square in section, the length of each side is 32 ÷ 4 = 8 ft.; and the sectional area is therefore 8 × 8 = 64 sq.ft. The velocity of the air, in this case, is, then, 80,000 ÷ 64 = 1250 ft. per minute.

Ques.—Explain the meaning of the term "manometrical efficiency," as used in fan ventilation, in estimating the efficiency of a fan.

Ans.—Manometrical efficiency is an expression indicating the ratio of the effective pressure due to the action of the fan, to the theoretical pressure or head of air column derived from the formula, $h = u^2/g$. The term has no practical value in estimating the efficiency of a fan, for the reason that the pressure a fan will create is determined by the resisting power of the mine. For this reason, the efficiency of the fan estimated on this basis will vary when operating on different mines.

Ques.—What must be the sectional area of a square airway that is required to pass 50,000 cu.ft. of air per minute under a 1-in. water gage, the length of the airway, including the return, being 1 mile?

Ans.—The airway being square, the length d of one side is calculated thus,

$$d = \sqrt[5]{\frac{4klq^2}{p}} = \sqrt[5]{\frac{4 \times 0.00000002 \times 5280 \times 50{,}000^2}{5.2}} = 11.5 ft.$$

The sectional area of this airway is therefore 11.5^2 = 132+ sq.ft.

Ques.—If the ventilating machine was permanently disabled by an explosion of firedamp, what temporary means would you employ to restore ventilation in the mine?

Ans.—At all gaseous mines, provision should be made for such an emergency, by the installation of a second fan that can be brought into immediate use should occasion demand. However, in the absence of such extra equipment and temporary repairs being impossible, it will be necessary to improvise some means for producing circulation of air in the mine. The means most effective and convenient is a steam jet placed in the upcast shaft. A fire basket hung in the shaft would be dangerous.

COAL AND COKE NEWS

Harrisburg, Penn.

According to figures compiled by the Central Pennsylvania Coal Producers Association, coal production in the central district is steadily increasing. The total for the month of June will not be far from 4,500,000 tons, making June the banner month of the present year. Production is still curtailed to some extent by car shortage, but not seriously.

The production for the week ending June 15 set a record, as 1,166,752 tons were turned out. The week ending June 8 was not far behind, with 1,166,494 tons, while the week ending June 15 showed a production of 901,839 tons.

The loss in production for the week ending June 15, because of inability to obtain cars, was 38,933 tons, while the loss for the week ending June 8 was 16,465 tons; for the week ending June 1 it was 14,359. Cars are equitably distributed among the producers, and thus none derives an advantage at the expense of the others, and the labor problem is in a fair way of being permanently solved.

It has been agreed among the miners and producers that production in the soft coal fields can be increased without resorting to either conscription of labor or lengthening of the working day. The miners are making good wages and there is little dissatisfaction.

The famous barrier pillar between New Boston and Mill Creek collieries, which contains half a million tons of coal, is to be mined. Court was informed during the week that the litigation which has been in progress twelve years to maintain this great pillar is ended.

The trouble began when the late John Curran, mine inspector of the 18th anthracite district, got an injunction against the coal companies to prevent the removal of the pillar, as otherwise the lives of the miners would be endangered by the sudden inrush of water. But both colleries are now being operated as one colliery, and State Mine Inspector E. G. Evans has informed the Schuylkill County court that under the present methods proposed continuance of the pillar is unnecessary.

About 150 representative coal operators of the central Pennsylvania district, meeting at Washington on June 27, recommended that the Fuel Administration close down any mine persisting in the practice of paying miners a bonus or otherwise violating the Washington wage agreement or the regulations of the Fuel Administration.

The action of the operators was taken on the warning of fuel officials that the bonus system threatens to unsettle the labor situation throughout the bituminous field. A resolution was adopted providing for a board of five members, composed of members of the association of bituminous coal operators of the central Pennsylvania field, which will be charged with the task of trying offending operators. Its findings will be subject to appeal to the Fuel Administration.

The membership of the board will be determined by a vote of the operators, and letters have been sent out through the central field asking for suggestions.

Fairmont, W. Va.

Last week proved to be another good week for the Fairmont district, with cars plentiful for loading. On last Tuesday, with 1754 cars in the Fairmont region, not a mine of the 174 reporting was shut down because of any lack of cars. It is stated by Fairmont operators that the good car supply in the region has been so well maintained that miners who have been following other occupations are returning to work in the mines. Still greater results are expected as the plans of the Fuel Administration, the United Mine Workers, the National Coal Association and the Central West Virginia Association are matured.

Much interest has been manifested in southern West Virginia in the proposal contained in the bill of Senator James Hamilton Lewis, to purchase 125,000 acres of coal land in West Virginia with a view to operating mines for the purpose of supplying the Army and Navy with coal, and to purchase the Virginian Ry. property. Of course, if the railways in the state, it is pointed out, are owned by the Government, the state will lose the taxes now paid by the Virginian Ry., and any other railways which the Government might acquire, and of course the additional tax burden would have to be met by the individual taxpayer. For that reason the purchase of the Virginian does not strike a responsive chord.

Charleston, W. Va.

That with fair transportation facilities the mines of the state are able to speed up production was demonstrated in the coal fields of Kanawha during the week ending June 22, when the total output was increased over 20,000 tons, the total net tons for the week ending June 15 having been 171,000 tons and for the week ending June 22, 193,885 tons, the increase being made possible simply because more cars were furnished and because the miners put in more time in the mine, as shown by the fact that the total number of hours worked was 7176—an amount much in excess of the time usually put in by miners. The hours lost due to car shortage were reduced from 2190 hours to 709 hours. On the other hand, the hours lost because of labor shortage jumped from 151 to 585 and further loss of time was caused by power shortage. Between June 1 and June 26 33,820 loads were delivered from the Kanawha district, 33,533 empties being received.

Even as mines in the Kanawha district on the C. & O. side of the Kanawha River had a plentiful supply of cars, so mines on the opposite side of the river reached by the K. & M. Ry. also enjoyed an excellent run of cars and were enabled to maintain their output. The supply this week is proving to be unusually good on both the K. & M. and in other parts of the district, averaging between 75 and 95 per cent.

New River mines were turning out coal this week at a rate which indicated an unabated determination to reach the apex of coal production if possible, and although the mines in the New River district have had to contend with power shortage at intervals during the last month, the companies operating in that district have managed to keep production up to a reasonable mark, especially since the Virginian has begun to furnish more cars.

Duquoin, Ill.

The firm of Dowell & La Font, of Duquoin, Ill., recently negotiated deals for land for the Union Colliery Co. and the E. G. Scott Co. The former coal company is opening up a new plant about five miles south of Duquoin. Other deals were in the interest of the Paradise & Franklin County Coal Co. and a stripping proposition for the Hamilton Coal and Mercantile Co., of Weir, Kan. A deal is just now being closed with the J. R. Coon Co., of Pittsburg, Kan. This company is one of the big stripping concerns of Kansas. Geo. W. Dowell, the senior member, of the firm of Dowell & La Font, is the chairman of the executive committee of the Perry County Council of Defense.

The E. G. Scott Co. proposition is the only stripping in this section of the state. The company controls about 150 acres of land on which there is a 6-ft. seam of coal. The overburden runs from 18 to 35 ft., including a little blue shale in places of an average thickness of 2 feet.

A Bucyrus shovel with a 90-ft. boom and 8 cu.yd. dipper has made the first cut, or box pit, and everything is in readiness for shipping coal. The steam shovel graded a track into the pit of 1.5 per cent. for 2300 ft. Railroad cars will be taken into the stripping and coal will be loaded into them by a small steam shovel. Shipments of coal will be made this month.

Terre Haute, Ind.

Car shortage is blamed for the decrease in total output for coal in the State of Indiana for the week ended June 22. A car shortage of 13.33 per cent. resulted in a loss of production of 142,520 tons by Indiana coal mines, according to reports to the district representatives of the Federal Fuel Administration. As a consequence there were hoisted during the week 588,211 tons as against 621,500 tons during the previous week. The car shortage was greater than it has been during any of the recent weeks. There was a loss of production of 3.24 per cent. because of labor trouble, and a loss of 5.88 because of mine disability. The greatest car shortage was on the Pennsylvania system, which lacked 30.33 per cent. of a full car supply. The shortage on the Chicago & Eastern Illinois R.R. was 11.11 per cent., and on the Chicago, Terre Haute & Southeastern 8.23 per cent.

Victoria, B. C.

No. 3 Mine, Crow's Nest Pass Collieries, in which an explosion causing the death of 34 miners occurred on Apr. 5, 1917, has been opened to the face after 14 months of unremitting work. When the inquest took place a few weeks after the accident only 22 bodies had been recovered. All are now accounted for, the majority having been found as the level was cleared and the last four about 10 days ago, when the face was reached. It is thought likely that the inquest will be reopened, the verdict returned last April having been that "death was caused by an explosion, but from the evidence adduced the jury is unable to assign the primary cause." It is claimed by those who have held that the explanation of the disaster would be found when the scene at the most remote working place could be surveyed, that the position in which the last four bodies was discovered to an extent bears out their contention. The evidence, however, seems to be conflicting. The men practically died at their posts. In each case their posture was such as would indicate that they had had some warning and had instinctively tried to shield their heads with their hands. One of their safety lamps was broken, and it is argued that this may have happened prior to the outbreak and be responsible for it. George Wilkinson, Chief Inspector of Mines, has left Victoria to make a careful examination of the mine and of the additional evidence secured.

PENNSYLVANIA

Anthracite

Inkerman—Announcement was made on June 29 of the closing down of No. 7 shaft of the Pennsylvania Coal Co. to make repairs and widening of the shaft, which will enable the company to use the standard-size mine car. The shaft is also to be sunk from the present Pittston vein to the Red Ash vein, a distance of 242 ft. While the rockwork in the shaft is progressing extensive inside improvements will also be made. It is estimated the improvements will take several months. The plans include a new steel tower and new first-motion engines. About 250 men employed at No. 7 will be given employment at No. 4 colliery.

Delano—The Hollywood colliery of Pardee Bros. & Co., Inc., abandoned 30 years ago as worked out, will be reopened this summer because of the great demand for fuel. A shaft cutting lower veins, deemed inaccessible in the 80s, has been driven, and tunnels are now being run to get out the coal. A complete electric equipment will furnish power. Work for several hundred miners will be furnished and the tonnage of the Pardee colleries will be materially increased.

Bituminous

Butler—The first coal-stripping operation in this county was put in operation July 1 when the first shipments were made from the pits of the Daylight Coal Mining Co. at Wahlville, near here. It is located on the Knauff farm in Forward township. The new operation is equipped with modern machinery throughout, with special means of preparing and cleaning the coal. The production at the start will be about 500 tons per day and will be shipped over the Buffalo, Rochester & Pittsburgh Ry. The general office of the company is at Indiana, Penn.

Punxsutawney—The former operations of John McCleavy & Co. near here, which were sold recently to Thomas A. Furniss, of this city, are in full operation again pending a temporary shutdown while many improvements were made to the mine. The new

mine, which was opened in the upper vein, is producing a high-grade coal. Shipments are made over the Punxsutawney branch of the Pennsylvania Railroad.

Republic—A contract has been let by the Thompson-Connellsville Coke Co. for the erection of 20 miners' houses here.

Connellsville—The Dawson-Connellsville Fuel Co. of this city will develop a tract of 100 acres of coal land near Fairmont, W. Va. The coal is the Sewickley vein. Frank A. Tarr, S. D. Henry and G. E. Moore are among the prominent Connellsville men interested in the new company.

Aultman—The Jefferson and Clearfield Coal and Iron Co. is building two new houses for its mine officials here. They are modern in every respect and are located near "the old farm house" near the company office. When completed they will be occupied by the superintendent and assistant superintendent.

Heshbon—A. J. Carnahan, Sr., has sold his coal lands near this place to "Square Deal" Campbell, a famous politician of Indiana County. Mr. Campbell, together with some New England capitalists, has formed a company and a drift has been opened in the "B" Miller vein. A railroad siding will be built up Palmer Creek from the Black Lick branch of the Pennsylvania R. R. to the new operations. The company will be known as the Square Deal Sulphurless Coal and Coke Company.

Johnstown—Colleges and historical associations in the bituminous region of Pennsylvania are petitioning for an unusual relic of the early days of mining, found in a pool in an abandoned working where it had lain submerged for many years. It is a coal car, 73 to 75 years old, which looks like a toy when compared to the cars of today. It is now in the possession of M. J. Bracken, general manager of the Inland Coal Co. The wagon is only about 2 ft. long and 18 in. deep, and would hold about five ordinary buckets of coal. It is constructed of wood. The wheels and axles are of wood. Over the wheels are tin "mud guards."

WEST VIRGINIA

Charleston—The Elkland Coal Co. of which C. L. Voglesang is general manager, having completed its plant on the Coal & Coke Ry., is now mining and shipping coal.

Crown Hill—A number of new houses will be built by the Crown Hill Coal Co. at Crown Hill for its miners.

Mahon—A number of new mining machines are being installed in the mines of the Eagle Byproducts Coal Co. at Mahan, on Paint Creek.

Thurmond—Operations will soon be resumed by the Stone Cliff Coal Co. which was forced to shut down its mine at Stone Cliff about two weeks ago when the monitor ran away, killing two men and injuring others. The incline and tipple were damaged, but repairs on them have been nearly completed. During the enforced idleness of the Stone Cliff mine Chesapeake & Ohio engines have been coaling at the Newlyn mine.

The Elkhorn Collieries plan to award a contract in the near future for the construction of 30 miners' houses at the headwaters of Colly Creek. The same company a little later will build 100 miners' houses on Thornton Creek.

Beckley—Within a few weeks the Piney Fire Creek Coal Co. expects to be shipping coal from mines it is just opening near here.

Charleston—The newly organized Boone County Coal Corporation has purchased the holdings of the Coal Valley Mining Co., on Coal River. The deal was consummated by Col. Quinn Morton, president of the latter company, and W. J. Clothier, of Philadelphia, representing the Boone County Coal Corporation. The sale includes the Sylvia mine in Logan County, which is a drift mine with a 5 ft. seam, employing 70 men. The price paid is said to be $250,000.

Welch—The Earlston Coal Co., with principal office and chief works at Kermit, Mingo County, has been organized by D. W. Farquharson and others of McDowell County. The company has a large acreage of coal on the Kentucky side of Tug River which it proposes to develop, but the chief works of the company, including tipple, power house and other buildings, will be on the West Virginia side of the river. The company has been capitalized at $200,000.

The Venture Coal Company, recently incorporated with a capital of $50,000, will develop coal lands in Upshur County. Those chiefly interested in the company are A. J. McDaniel, Oscar Cochran, Henry King, Charles R. Atha and J. D. Victor, of Worthington.

Bluefield—At a meeting of the directors of the Bradshaw Coal Co., held here last week, it was decided to enlarge the facilities of the plant located on the Dry Fork line near English and to operate the company's mines on a larger scale, officers being authorized to proceed with improvements necessary to bring the output of the operation up to capacity.

Clarksburg—A syndicate of Johnstown (Penn.) coal men has purchased the plant and coal lands of the Trainor Coal Co. of Salem, located near Monongah, the price being about $80,000. J. W. Preston acted as trustee for the syndicate.

Fairmont—Fairmont men are interested in a new company—the Dawson Connellsville Fuel Co.—recently incorporated in this state with a capital stock of $120,000 to operate mines on the West Fork River opposite White Day on the Baltimore & Ohio, where the company owns 100 acres of Sewickley coal. The mine will be equipped with electrically driven machinery. A conveyor will also be erected.

OHIO

Shawnee—The Buckeye Coal and Railway Co., of Columbus, started loading July 1 from the old Buckingham mine, located on the Zanesville & Western about midway between Shawnee and Corning. The mine was one of the large operations of the Sunday Creek Coal Co. 23 years ago, when it was abandoned because of much acreage on which a minimum royalty was required. Several weeks ago it was decided to reopen the operation and the water, which has filled the mine for 23 years, was pumped out. It was found that the ties were in excellent shape but the steel rails were mostly rotted. The mine has now been electrically equipped and has been put in first-class condition. The seam is 10 ft. thick, of which 6 ft. is the ordinary No. 7 vein and the remainder a sort of splint which was not mined up to the time of the abandonment of the mine.

KENTUCKY

Madisonville—The Hopkins County Realty Co. has leased to the Sunset Coal Co. the mining rights to the McPherson tract, containing about 125 acres of coal land, and also the coal under two tracts of land at Elk Creek.

It is understood that W. D. Coil, of the Coil Coal Co., has leased from the Hopkins County Realty Co. the No. 9 seam under 750 acres of land, and that Mr. Coil, who is mayor of the city, will install a shaft mine, loading out on the Louisville & Nashville tracks.

Carrollton—The Beattyville Coal Co., operating mines at Beattyville, and boats and barges on the Kentucky River, has purchased from Oscar Barrett, of Cincinnati, the property of the Frankfort Elevator Coal Co., on the river-front at Frankfort, and plans to handle coal from the Kentucky River mines through this plant.

Hazard—The Blue Diamond Coal Co. recently established a new record for the district when 40 cars of coal were loaded out in one day by its double tipple, which has just been completed at White Oak, on First Creek.

The Montgomery Creek Coal Co., recently capitalized at $100,000, plans installation of plant on Montgomery creek, of Carr's Fork, where a spur track is now being laid. J. W. Reedy and G. W. Smith are the principal backers of the company.

INDIANA

Indianapolis—Production of coal by Indiana mines reached a high figure for the week ended June 15. Reports to the district representative of the Federal Fuel Administration showed that there were hoisted during this period 621,501 tons as against 621,436 during the preceding week. This production was accomplished in spite of a car shortage of 11.16 per cent. as against 7.23 per cent. for the preceding week, the difference in ratio being accomplished through increased efficiency of the mines and through a considerable decrease in the amount of labor trouble which caused a loss of only 1.76 per cent. of time as against 2.93 per cent. for the preceding week. With a 100 per cent. car supply the Indiana production would have been more than 700,000 tons. The greater part of last week's production was mine-run coal, with which the domestic demand is being supplied to a considerable extent. Production of lump coal is being delayed by the sluggishness of the market for screenings.

ILLINOIS

Moro—George Prescott, of Centralia, has organized and incorporated the Moro Coal and Mining Co. to revive the coal-mining industry in the Moro district. Prescott is president of the company and the other officers are Stanley Kolwolkowski, vice president; Thomas M. Kekich, secretary, and Fred F. Reinhardt, treasurer. All except Reinhardt are practical coal men. Reinhardt is a banker at Sandoval, Ill. The company has taken over the George Kabel mine and will install modern equipment, including power machines, steam hoisting engines and an 8-ft. power exhaust fan. About 400 acres of additional coal land adjacent to the shaft has been acquired, and more is being negotiated for. A 6-ft. vein underlies the district, with a percentage of 64 per cent. fixed carbon. Business men will erect homes for the miners and sell them on easy payments. The company will have its headquarters at Alton.

Galesburg—The Cripple Creek Mining Co. has opened a new coal mine at Bryant, Ill., and represents that the vein is No. 5, of the Illinois series, which is extensively mined over the coal section of the state and is counted as a good coal. The company has had some tests made which are satisfactory. The coal is clean and burns well. The prospect now is that the plant will be ready to ship coal by July 15. The name given to the new coal is Carbon Lump.

KANSAS

Baxter Springs—The O. B. Ross Mining Co. has been organized to mine coal in the newly discovered coal field near here, and Superintendent O. B. Rose is now putting down a shaft on the J. McSherry farm, which is west of Baxter Springs. The coal, which is 5 ft. thick, is found at a depth of 52 ft. In one borehole coal was struck at a depth of 180 ft., mixed with zinc. Baxter Springs is in the heart of the Oklahoma-Kansas zinc mining field.

Personals

Ernest Hutton, well known in the mining circles of Fairmont, W. Va., has recently become identified with the Jeffrey Manufacturing Co. of Columbus, Ohio, manufacturer of coal-mining machinery equipment, and will represent it in the Fairmont territory.

A. Niedermeyer, for many years connected with the Worthington Pump and Machinery Corporation, most recently as works manager of the Snow-Holly Works of that corporation, at Buffalo, N. Y., resigned on May 31 to devote his entire time to enterprises of his own.

A. B. Cole has been appointed assistant to the manager, Department of Publicity, of the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn., to succeed M. C. Turpin, who has accepted a position in the Ordnance Department at Washington, D. C. Mr. Cole will have charge of the editorial work, including the preparation of literature, and supplying information to the press.

Polyphase Induction Motors. General Electric Co., Schenectady, N. Y. Bulletin No. 41302A. Pp. 12; 8 x 10½ in.; illustrated. Gives the construction details of company's 15 to 200-hp., Type KT, Form B, induction motor.

Leyner Shank and Bit Punch—I-R Type. Ingersoll-Rand Co., New York, N. Y Form 4039. Pp. 4; 6 x 9 in.; illustrated. Describes Leyner shank and bit punch for punching out holes in bits and shanks of hollow drill steel.

Form 901. Ingersoll-Rand Co., New York, N. Y. Four-page flyer showing the complete line of "Little David" pneumatic tools. Tables of sizes and capacities are given and illustrations show all the tools and their applications.

Blueprint Machinery and Drafting Room Supplies. C. F. Pease Co., Chicago, Ill. Catalog B. Pp. 272; 6 x 9½ in.; illustrated. This is an exceptionally well-prepared catalog, bound in hard covers, and excellently illustrated. For easy reference the book has been divided into seven classifications, an index affording easy guidance to one seeking details and prices on drafting-room supplies.

Industrial News

Danville, Va.—The Southern Railway Co. is considering the construction of a new coal chute at its local plant to cost about $30,000.

Newark, N. J.—The Edison Storage Battery Co. has established a new sales office in Kansas City, Mo., appointing Benjamin F. Eyer as resident manager.

Chicago, Ill.—W. H. Callan, general manager plants, and W. P. Pressinger, general manager sales, of the Chicago Pneumatic Tool Co., have been elected vice presidents of the company.

Charleston, W. Va.—An operation will be started at Queen Shoals, W. Va., by the Five Block Coal Co., recently incorporated with a capital of $300,000. A. J. Salzer and others are interested.

Kenmore, N. Y.—The Board of Education has taken bids for the construction of a new one-story coal storage building, about 25 x 75 ft. William A. Kidd, 250 Delaware Ave., Buffalo, is architect.

Coal Center, Penn.—The Haney Coal Co. has awarded a contract to the Enterprise Contracting Co., Bessemer Building, Pittsburgh, for the construction of a new coal-loading plant at its works to cost about $6000.

Norton, Mass.—The Defiance Manufacturing Co., located in the Barrowsville section of Norton, has commenced the construction of a new coal plant at its works. George E. Carver, 53 State St., Boston, is engineer for the company.

Baxter Springs, Kan.—The O. B. Ross Mining Co., which is developing a coal tract near here, under the superintendency of O. B. Ross, is in the market for hoisting machinery, belts, steam engines, pumps, boilers, cars, track and lumber.

Pittsburgh, Penn.—The Aspromet Company of Pittsburgh (formerly the Asbestos Protected Metal Co.) announces the removal of its Chicago office on July 1, 1918, to the Railway Exchange Building. J. T. O'Neill will continue in charge as district manager.

Constable Hook, N. J.—The United States Government, Bureau of Yards and Docks, has awarded a contract to the Guarantee Construction Co., 140 Cedar Street, New York, for the construction of the proposed new local coaling plant. The structure is estimated to cost $130,000.

Nelsonville, Ohio—The Hazel Ridge Coal Co., recently incorporated with an authorized capital of $15,000, has taken over the operating mine started by D. M. Poston, who, after getting the mine near Nelsonville in operation, enlisted in the army. George Biermann, of Nelsonville, is the general manager.

St. Louis, Mo.—The St. Louis Fuel Committee has refused the following applications for reclassification: Lumaghi Coal Co., Canteen Mine, Collinsville, Standard to Mt. Olive; Southern Coal, Coke and Mining Co., Shiloh mine, Belleville, Standard to Mt. Olive; Northern Coal Co., Gallatin County, Carterville to Duquoin. The reclassifications were asked mainly on the ground of the superior preparation of the output. Other applications are pending.

Toledo, Ohio—Lake trade is still active, as is shown by the activity at the dock of the Hocking Valley and Toledo & Ohio Central at this port. During the week ending June 28 the Toledo & Ohio Central loaded 63,735 tons as compared with 71,000 tons the previous week, making a total for the season of 638,735 tons. The Hocking Valley Railway Co., during the same week, loaded 140,450 tons as compared with 144,634 tons the previous week. The total for the season is 1,177,377.

Louisville, Ky.—The Gordon & Miller Coal and Coke Co., composed of Ross E. Gordon, J. S. Miller and Boyce Watkins, has recently arranged to take over the improved mine of the Lynndale-Jellico Coal Co., at Lynndale, Ky., near Barbourville, on the main line of the Knoxville division of the Louisville & Nashville. The company has a tipple and trackage into its plant. It is planned to put in additional machinery, a power plant and other equipment to increase the capacity to about 20 cars a day.

Cincinnati, Ohio—Reports from Morgantown, W. Va., indicate that the Morgantown & Kingwood R.-R., operating 48 miles between Morgantown and Rowlesburg, W. Va., and serving a number of coal mines, may suspend operations on account of inadequate revenues, unless some remedial action is taken soon. That date has been fixed by the management as the date of suspension. However, it is understood that if suspension actually takes place the Government will intervene in order to prevent the coal mines on the road being left without railroad facilities.

Huntington, W. Va.—At a recent meeting here of the directors and alternates of the West Virginia Coal Association and secretaries of district associations, resolutions were adopted pledging the coöperation of the association with the United States Fuel Administration, the National Coal Association and the State Council of Defense. The following officers were elected to serve for the ensuing year: J. G. Bradley, chairman, Dundon, W. Va.; G. H. Caperton, vice chairman, Charleston, W. Va.; A. H. Land, treasurer, Logan, W. Va.; W. H. Cunningham, secretary, Huntington, W. Va.

Charleston, W. Va.—The capital stock of the Harvey Coal and Coke Co. has been increased under authority of the Secretary of State from $250,000 to $500,000. The president of this company is R. H. Gross, who is also president of the large New River Co. Other companies of which Mr. Gross is also president have increased their capital stock as follows: Stuart Colliery Co., from $500,000 to $1,100,000; Prudence Coal Co., from $100,000 to $300,000; Mabscott Coal and Coke Co., from $135,000 to $250,000. On the other hand, the Loup Creek Colliery Co. has reduced its stock from $2,000,000 to $800,000.

Columbus, Ohio—The Charleston Coal Mining Co., incorporated by Columbus men several months ago, has been organized to take over the operating property of the Charleston Domestic Coal Co., located on the edge of Charleston, W. Va. The capitalization is $125,000, a greater part of which is being sold to miners. J. S. McVey, of the Central West Coal Co., is president; F. J. Fried, vice president and treasurer, and H. E. Varga, secretary. Additional machinery will be installed to increase the capacity of the plant. The product is to be sold by the Central West Coal Co., of Columbus.

Welch, W. Va.—The Bradshaw Coal Co., which recently purchased all the holdings of the Bradshaw Pocahontas Coal Co. and adjoining land, incorporated under the laws of Virginia, held its first stockholders' meeting at Graham, Va., on Tuesday, June 25. Edward Mann, of Bluefield, was elected president; R. J. Hancock, of Lynchburg, Va., vice president; G. S. Strader, of Bluefield, secretary-treasurer. The following directors were elected: Edward Mann, G. S. Strader and Walter Perkins, of Bluefield; R. J. Hancock and R. C. Scott, of Lynchburg; L. A. Osborn, of Welch, W. Va., and C. L. Biddison, of War Eagle, W. Va. C. L. Biddison will be general manger.

Chicago, Ill.—The Allen & Garcia Co., McCormack Building, Chicago, Ill., have been appointed constructing engineers by the Donk Brothers Coal and Coke Co., St. Louis, Mo., in charge of the design and construction of its new No. 4 mine near Edwardsville, Ill. This will be the fourth new mine in the state of Illinois, designed or constructed within the last year, on the basis of skip hoisting and rotary dump at shaft bottom. Another new feature in connection with this property will be the level surface yard, all railroad cars to be handled by shunter locomotive instead of the uncertain gravity system. The power plant will be constructed with a view of supplying electric energy for the operation of mines Nos. 5 and 6, which will be developed after No. 4 is completed.

MARKET DEPARTMENT

Weekly Review

Production of Bituminous Keeping up Well—Where the Coal Is Going—Some Conservation Plans—Stimulating Labor in Soft-Coal Mines—Anthracite Situation Serious—Demand for Coal Active—Lake Shipments

THOUGH the production of bituminous coal for the week ended June 22 totaled 12,016,000 net tons, a decrease of 610,000 net tons when compared with the output for the week ended June 22, production was at the rate of 643,000,000 net tons a year, or 11,000,000 net tons above the average rate in the record-breaking year 1917.

Even at this rate of production it appears that the mines will be unable to furnish enough coal to meet all needs, which serves to emphasize the fact that the demand for fuel is unprecedented.

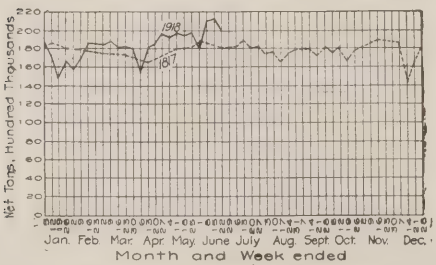
Where is all the coal going? It would seem almost needless to answer this question. There's the iron and steel industry, for example. The production of coke is this year larger than ever before, and still the blast furnaces cannot get all the coke they need. Furthermore, it must be remembered that every ton of coal converted into coke has been counted in with the figures of coal production each week. The large tonnage of coking coal consumed by the blast furnaces should therefore be deducted from the amount available for other industries. The steel mills, too, at this time are using a larger proportion of pig iron than in normal years, and a ton of pig iron converted into steel means, in the long run, more coal consumption all along the line than a ton of pig iron used in the iron foundry.

The tinplate mills, which consume more coal per ton of output than any other important branch of the general iron and steel industry, are also running at maximum capacity. Then again, the railroads are consuming more coal than ever before. What is true of the few industries mentioned is equally true of every war plant today.

It can readily be seen, therefore, that the strictest kind of conservation must be practiced in order for the country to pull out on the right side. The Fuel Administration has perfected quite a few plans to cut out the wasting of coal, and not the least ambitious of these is the proposal to save several million tons of coal by effecting economies in power plant consumption. There are 250,000 industrial power plants in the United States. At many of these the amount of coal waste is considerable. Every power plant east of the Mississippi River is to be visited by an inspector and given a rating based on the thoroughness with which the owner carries out the conservation recommendation. The plan is based on the use of the existing equipment without the installation of fuel-saving apparatus. Plants which are prodigal in the use of coal will either have to reform or do without fuel.

Another plan is to save the coal consumed in needless illumination. Failure on the part of nearly every city and town in the country to prevent a waste of electricity has made necessary new action on the part of the Fuel Administration, and before long Dr. Garfield may again invoke his "lightless night" order.

While busily engaged in conservation work, the Fuel Administration has not lost sight of the fact that production must be stimulated to the *n*th power. The mine workers are being exhorted to work full time instead of laying idle whenever the whim seizes them, and the final interment of the assigned car policy assures an equitable supply of empty cars to the mines. If labor in the bituminous coal regions can be induced to work regularly and faithfully, there need be no serious shortage of fuel for all essential industries.



The anthracite mine workers, on the other hand, though not lackadaisical and pleasure-seeking to the same extent as their brethren of the soft-coal regions, are not great enough in number to produce the necessary tonnage of hard coal. Production for the week ended June 22 amounted to 41,170 carloads, which is on a par with the shipments of previous weeks. The continued drafting of employees has placed the hard coal operators in serious straits, and this is forcibly illustrated when it is known that for every man lost to the industry the nation loses 600 tons of coal a year. The magnitude of the loss is further emphasized in the fact that 33,000 mine workers have been withdrawn from the collieries since the war started, which translated into labor power means an annual loss of nearly 20,000,000 anthracite tons of marketable coal.

The market is characterized by a strong demand in nearly every branch. Domestic stocking continues strong, and is taking practically every ton of coal in dealers' yards. With a higher percentage of domestic requirements taken care of by summer storage, it will be possible to concentrate more generally on the industrial supply.

So far shipments to the lakes have not been up to expectations, and a movement of more than 1,000,000 tons is reported from the head of the lakes. Vessel movement is active, and fewer bottoms are going to the upper lake region light. Heavier shipments will be necessary this month to maintain schedules and supply the Northwest before winter sets in.

COAL PRODUCTION

A sharp decline in production of bituminous coal occurred during week ended June 22. The output of soft coal (including lignite and coal made into coke) is estimated at 12,016,000 net tons, a decrease compared with the week of June 15 of 610,000 net tons, or 5 per cent., and an increase over the same week of 1917 of 701,000 net tons, or slightly over 6 per cent. The average production per working day during the current week is estimated at 2,003,000 net tons as against 2,104,000 net tons during the preceding week and 1,888,000 net tons during the week of June 22,

1917. Shipments from all districts decreased during the week of June 22. Shipments from Ohio and Alabama decreased the most, from the former fields the decrease amounted to 7 per cent. and from the latter fields 12 per cent. Central and western Pennsylvania shipments decreased 4 per cent.

Anthracite shipments during the week of June 22 amounted to 41,170 cars, a decrease of 790 cars or 1.9 per cent.

Beehive Coke—A considerable decrease in production of beehive coke in the United States occurred during the week ended June 22. Preliminary estimates place production at 604,000 net tons as against 661,000 net tons during the week of June 15 and the average per working day at 101,000 net tons compared with 110,000 net tons during the preceding week. The principal operators in the Connellsville, Greensburg and Latrobe district of Pennsylvania report production of beehive coke during week ended June 22 at 391,869 net tons, the ovens being operated at 75.5 per cent. of their present capacity, as against 77.2 per cent. during the week preceding. During the week slight improvement occurred in transportation conditions, but such improvement was entirely offset by greater losses due to shortage of yard labor. The same operators produced 143,500 net tons of coal.

Byproduct Coke—Operating conditions in the byproduct industry improved further during the week ended June 22, the plants being operated at 89.5 per cent. of their present capacity as against 88.5 per cent. during the week of June 15. A better supply of byproduct coal and improved labor conditions are reported for the country as a whole, while repairs to plants caused slightly greater losses than during the week preceding. Material improvement was reported by operators in Indiana, Kentucky and Tennessee while operators in Alabama, New York and the western states report the only material decreases.

BUSINESS OPINIONS

Bradstreet's—Industrial movements propelled by Government orders are intensely active, readjustments to a war basis implying regulations of one kind or another loom larger than anything else, and in consequence fresh operations in ordinary business lines proceed at a halting gait. With the Government exercising priorities, regulating prices, and taking such goods as are needed, free trading on civilian account is out of the question. This condition is responsible for the universal cry of a shortage of merchandise and the inability of jobbers to fill orders. In such lines as textiles, trade has almost halted pending definite views as to the Government's final action on prices. Potentially fall business is of large proportions, but the general attitude is to defer placing orders for distant delivery until it can be seen which way and how far the price pendulum is likely to swing.

American Wool and Cotton Reporter—Many are convinced that when wool is apportioned for civilian production that some definite arrangement will be made in regard to prices of woolen goods. It is believed that it is the settlement of this detail more than the raw wool supply which is holding back regulation. Raw cotton remains high even with the visible supply accumulated because the cotton grower or the holders are firmly convinced that the actual amount obtained from the growing crop will not be especially large, even if present indications point to this fact, and also because it is not the basis of domestic supply, but the basis of world supply on which prices must be regulated.

Dry Goods Economist—While the War Industries Board has announced that a large portion of the raw wool stock now in this country, and all of the wool to be produced or imported prior to Jan. 1, 1920, will be required for military uses, the board also declares that the stocks of clothing and cloth on hand will be adequate for essential civilian needs. The board also gives assurance that wool will be equitably distributed to meet both Government and civilian requirements and that prices will be so regulated as to assure a fair and reasonable profit to the industry and at the same time prevent abnormal profits.

Marshall Field & Co.—Current wholesale distribution of dry goods for the week is substantially ahead of shipments for the corresponding period a year ago. Road sales for both immediate and future delivery show a good increase over those of the same week in 1917. Customers have been in the market in slightly smaller numbers than last year. Collections are satisfactory, showing an increase over those for the corresponding week a year ago.

Atlantic Seaboard

BOSTON

First quarter of coal year passed and receipts far short of schedule. Coastwise shipping has caught up with the program and railroads have not been offered the tonnage they could have moved, but the volume of coal has not been forthcoming. Arrears since Apr. 1 amount to 2,000,000 net tons bituminous. The 4500 cars weekly quota from central Pennsylvania all-rail yields less than 70 per cent. and a reduction is probable. Apparent fluctuations in program make it extremely difficult to plan distribution and "protect" preferred requirements. Situation bound to develop fast as season advances. State administrators rule on extra compensation for shippers who distribute over wharves not their own. Anthracite program also falls down. Effort made to restrict domestic sizes from manufacturers and other steam users requiring bituminous to be used as a substitute. Query arises, whence will come the bituminous?

Bituminous—The trade is now able to view the results of fuel regulation so far as concerns the volume of coal received in New England. The situation here seems extremely hard for Washington to grasp, and notwithstanding all the representations made and assurances given, this territory at the end of three months since Apr. 1 is falling steadily behind in receipts, and this during the season of most favorable movement and at a time when stocks must of necessity be accumulated. A program for 30,000,000 net tons for the coal year, two-thirds by water and one-third all-rail, April to October movement to be 3,000,000 tons monthly and October to April to be 2,000,000 tons monthly, was arranged early in March, and it was put up to the Shipping Board and the Railroad Administration to move the coal when the necessary volume was produced. It is now perfectly plain, at the end of three months, where the weakness has been in the March program. At the time everybody was agreed that the greatest bar to a full operation of the program would be the shortage of ships. It meant adding to the available steamers in the coastwise coal trade more than 150,000 tons, and notwithstanding all the difficulties this has been done. Steamer tonnage has been steadily increased until on July 1 the total exceeds the mark set in early March. There are now in service 94 ships against the 40 in the trade as late as in the latter part of April.

The railroads also have moved with dispatch all the coal offered them by the connecting lines. It is recognized now that transportation generally has caught up with coal output, and in New England for the three months the showing is impressive. While the average movement via the five New England gateways was 664 in March and 717 in April, the daily receipts in May dropped to 535. Figures for June are not complete, but for 28 days the average for commercial coal was 527. In other words, the present movement all-rail is still far below what it was in April and is even slightly below what it was in January. A month ago it was clearly stated that the New England roads could handle at least 500 coal cars more a day, but this would of course include anthracite both in steam and domestic sizes. Railroad fuel is still being received in less volume than normal, and certainly we are in for serious times if a greater effort is not made soon to build up stocks for the New England carriers.

The net result of sending coal to points other than New England is a shortage of nearly 2,000,000 net tons for the three months since April 1. This is of course on the basis of 3,000,000 tons monthly, as agreed upon in March, and since this serious deficiency is in volume of coal and not in transportation, it is only natural that the trade here should look to the fuel authorities to see to it that deliveries here are on the proportionate basis outlined early in the year. Much prominence has been given to the 4500-car order, so-called, and even yet there is a great lack of understanding of what the order really meant.

The order went into effect June 10, but so far as returns have come in the order has not yet yielded 70 per cent. When it was issued there was a general understanding this accelerated all-rail movement was in no way to conflict with shipments by rail and water via New York and Philadelphia piers, but except for certain routine shipments for railroad fuel and important industries to which coal continues to run the movement in this direction has fallen off to such extent that emergency shipments for account of the New England Fuel Administrator have disappeared entirely. The scheduled movement via tidewater piers from central Pennsylvania was to be 1125 cars weekly. This added to 4500 cars all-rail would amount to 5625, but again there is a flaw in the program, at least in practical operation. It is now strongly intimated that the total movement via both routes is to be something over 4750 cars weekly, and therefore should the quota be reached by either route the supply in the other channel would most seriously fall off.

Anxiety increases week by week, and a large number of consumers are running on hand-to-mouth deliveries. Only in a few scattered instances has there been any opportunity to get reserves, and the railroads are still the most glaring cases where limited stocks are the rule. They, too, have joined the ranks of those determined to use steam sizes of anthracite in power plants, and the volume of buckwheat and silt bids fair to increase rather than diminish. This will be the case probably up to the time when the shippers will not be able to load fast enough to keep up with the demand. Should car supply in the anthracite region be at all affected, the supply of steam sizes would be the first to be curtailed.

On every side the situation is most complicated and difficult for local fuel authorities to supervise. With the program from Washington changing from time to time, it is impossible here to fix upon an adequate plan for proper distribution. No one is yet able to say what is "protection" for a preferred requirement. For the present, the local mark is three weeks.

As a result of the hearing in Boston on June 18 the Massachusetts Fuel Administration fixed upon 23c. (including purchasing commission) as sufficient compensation for shippers who handle bituminous in their own or chartered transportation and distribute over wharves not their own. This was to carry out the provisions of Rule 23, issued from Washington on or about June 1. Some shippers had asked for 5 per cent. of the delivered price, or 40@45c., while others had asked that no increase be granted. The decision is therefore a very moderate concession to those who thought 15c. not enough.

Anthracite—Shipments of domestic sizes show no substantial increase over recent weeks. June receipts by water were less than in May, although complete figures are not yet in hand. For 28 days in June the average daily receipts of domestic sizes all-rail were 581 cars. Steam sizes averaged 190 cars daily for the same period. One of the larger shippers advanced prices 25c. on these sizes on June 12.

A determined effort is being made to shut off domestic sizes from manufacturers for steam use. The amount of this tonnage, especially that which has replaced coke, is surprising; but if all this is to be replaced in turn by bituminous, the query may well be raised, Whence will come the bituminous?

NEW YORK

Dealers are gloomy over the outlook and hope that receipts will increase shortly. Division of fuel district in New York State opposed. Committee of Bronx taxpayers to see Dr. Garfield. Demand for the steam coals continues heavy. The bituminous situation serious. Free coals are scarce and large consumers become anxious.

Anthracite—The optimism prevailing in Fuel Administration circles as to the outlook is not so much in evidence among the trade. The shortage seems to be as heretofore, and the dumpings at the local piers for the week indicate one more car emptied than was dumped during the previous week. Receipts are not anything like the trade would have them, and complaints are numerous.

The reports emanating from Washington that it is contemplated to appoint a Fuel Administrator for the upper part of the state does not meet with the approval of the trade, and there is said to be much opposition to a divided fuel district in this state. Coal men, however, are solid in the belief that a State Fuel Administrator should be appointed at once, otherwise they are of the opinion this state will face a serious fuel situation next winter.

The situation in Bronx County is so desperate that a committee of taxpayers will shortly visit Dr. Garfield in Washington and present to him the claims of that county. It is the opinion of these taxpayers that the county is being discriminated against and that preference is being shown to New England in the way of shipments. It is claimed that during the year ended Mar. 31, 1918, there were consumed in the county 870,977 tons of coal, while the allotment made by the Fuel Administrator for the current year is but 850,975 tons, although the dealers have applied for 1,344,000 tons. It is proposed to place these and other facts before Dr. Garfield and show him that unless more coal is sent to the dealers there will be many heatless houses in the Bronx next winter.

Unless the order to the Anthracite Committee sending an increased tonnage into New England is renewed, receipts here ought to show a big increase his month.

For the week ended July 1 the dumpings of anthracite recorded at the tidewater docks in this harbor were 7426 cars, or one car more than the previous week. For the month of June there were dumped 30,713 cars. Shipments of anthracite as reported by Government statistics for the week of June 22 showed a falling off of 790 cars as compared with the previous week, 41,170 cars having been sent to market as against 41,960 cars for the week ended June 15.

Operators are anxious about the labor situation at the mines and predict a still greater shortage of coal unless the War Department acts quickly in exempting miners from the draft law provisions.

The activity in steam coals continues, much of the demand being due to the efforts to use barley and culm in place of bituminous or in mixing these sizes with it, owing to its scarcity. Buckwheat No. 1 is nearly as scarce as the domestic coals. Rice and barley are easily moved, some of the railroads storing quantities of the latter size for next winter.

The demand for all sizes among the line trade is heavy. Dealers in some localities say they have delivered as much coal as they usually have placed in bins by Aug. 1.

Current quotations, per gross ton, f. o. b. tidewater at the lower ports, follow:

	Circular	Individual		Circular	Individual
Broken	$6.50	$7.25	Pea	$4.90	$5.65
Egg	6.10	6.85	Buck	4.85	5.60
Stove	6.35	7.10	Rice	4.35	4.80
Chestnut	6.45	7.20	Barley	3.85	4.00

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice and barley are not fixed by the Government.

Bituminous—There has been no letup in the demand, and dealers see no increase in receipts. There is still much dissatisfaction over the preference order for New England, it being felt in local circles that New York is the loser.

Definite announcement by the railroads fix the freight rates on coal coming to South Amboy from central Pennsylvania and to St. George from certain districts along the Baltimore & Ohio at $2.15 per gross ton, to which the war freight tax of 3 per cent. is to be added, an increase of 50c. per ton. The rate to the upper ports is 5c. per ton higher.

Stocks here show no increase. Free coals are hard to find, while regular customers are getting just about enough to supply their immediate needs. There were 7228 cars of bituminous dumped at the local tidewater docks in the seven days ended July 1, as against 7239 cars the previous week. For the month ended June 30 there were 30,861 cars of bituminous dumped. During the week ended June 22 there were 212,886 cars of bituminous shipped to market, as compared with 222,892 cars shipped the previous week, an increase of 10,006 cars.

Large consumers are becoming alarmed over the situation and are not optimistic of the future. The railroads are preparing to store large quantities for winter, but are not able to obtain anything like the tonnage they would like.

After considerable work on the part of a committee of The Wholesale Coal Trade Association of New York, jobbers are to be allowed a margin not to exceed 35c. per ton on coal physically handled by them. This margin is allowed them as a result of an order issued by Ellery B. Gordon, assistant to state fuel administrator. This margin is to be added to the mine price of the coal plus freight rate to tidewater plus war tax on freight plus demurrage plus actual harbor boat charges.

Current quotations, based on Government prices at the mines, net ton, f. o. b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite situation grows serious. Receipts shorter than for two months. Quotas for large buildings cut. Buckwheat to be conserved. Schools to get full tonnage. Rent raisers taken in hand by fuel com-

mittee. Strong hope for improvement in July. Quotas increased 18%. Questions raised by freight increase. New labor problem. Bituminous car supply about 50%. Fair shipments locally. Improved tide movement. Brokers do fair business.

Anthracite—The past week has been one of great publicity to the retail coal trade. The newspapers have printed interviews calling attention to this city's need for anthracite. In an effort to offset another coal shortage next winter, the fuel authorities began reducing the supply to various large buildings. For over a month a large number of inspectors under instructions from the fuel conservation chairman has been visiting apartment houses, stores and manufacturing plants, checking up statements made in answer to a questionnaire concerning their fuel needs, together with the equipment for economical combustion. It is claimed that many faulty statements have been received, and it is probably due to this that drastic cuts will be made. The fuel administration seems determined to conserve fuel for the homes in every possible way and will see to it that only minimum supplies are furnished to large buildings. While it is stated that no war industry has yet been curtailed, it is the intention during the coming winter to care for the homes first, then the war plants and then the non-war concerns last.

In this connection it can be said that the list of plants refused permission to purchase buckwheat grows in number. As a consequence those plants which have been granted exemption have been enabled to increase their storage piles quite considerably. Among this latter class are a number of concerns who are not strictly on war work, and it would be no surprise at all when winter comes to see such stocks commandeered for domestic use.

The number of retail firms refusing to book additional orders until those on hand have been materially reduced is growing almost daily. It was reported this week that the largest concern in the city had now taken this stand. In the meantime those with orders on the books continue to urge the delivery of the coal.

With the month of June now closed it must be said that the coal receipts for the city were most discouraging and are understood to be much below those of April and May. Just how far short of the actual needs of 233,000 tons per month, which is the basis for the yearly estimate as announced by Chairman Lewis, has not yet been ascertained, but the shortage has been estimated by various interests at 75,000 to 80,000 tons; and using the latter figure, this would make the June receipts of domestic coal 153,000 tons, which we feel is about accurate. However, as we start into July at least one of the big operating companies claims it expects to give all its local trade a goodly increase. So far as we can learn this is predicated on the fact that it will this month make shipments with all quotas increased 18 per cent as announced by the fuel authorities some time since. Action on this increase has been postponed from time to time with the hopes that this city would be granted a heavier increase than 18 per cent., but it is stated for the present this will not be done.

Referring to the new freight rates, it is interesting to note that there are now only two rates, that of $1.90 for domestic coal and the other $1.70 for pea and smaller. This latter classification is an innovation, as before the recent 45c. advance pea was $1.25 and the steam sizes $1.20, and for many years there was such a variation. The above rates, of course, are for the most direct routes to the city, the differentials via the other roads still making those rates higher, as usual.

The labor situation among the retailers does not improve, and is really almost as serious a factor as is the slowly diminishing number at the mines. It is next to impossible to get men to make retail deliveries, and when they do work they surround the job with conditions that make their retention almost worthless. In order to help this situation a ruling has now been made that retail dealers will not be required after July 1 to make deliveries in the customer's cellars where the coal cannot be chuted from the wagons. Heretofore an extra charge has been made for carrying the coal, but it has been so difficult to induce men to do this that the fuel authorities have ruled that in such cases the customer must either do this work himself or provide the necessary labor. Of course, all dealers do not expect to apply this rule, except where it is absolutely necessary.

The demand for all steam grades continues unabated, with the usual exception that culm is quite free. Locally the demand for this does not increase, but in the eastern market there has been no diminution, although some whispers of complaint are being heard that the cars used for this coal might be used to better advantage on other sizes.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—In the soft-coal trade car supply still dominates the situation, as there has been little or no improvement recently. It seems that the golden days of a few weeks past when an almost 100 per cent supply, based on present production, was to be had, is now but history. There continues to be some chafing over the 900-cars-per-day order to New England, and we really doubt if that many cars are now going forward. The local consumers are receiving a fair tonnage and most of the vital plants continue to be able to store good supplies. This is particularly true of public utilities, where the visible stocks are getting close to normal. It has now been some time since it has been necessary for the fuel administration to divert any tonnage. Of course, this is due to the better production, but much credit also belongs to the bituminous distribution committee of operators who are now handling this work for the administration. Tide shipments are increasing now that the submarine flurry seems to have subsided. In the brokerage trade many of the houses are receiving fair supplies by following the plan of permanently locating representatives in the region and buying stray cars, particularly from wagon-mine operators.

BALTIMORE

Rather remarkable lack of stimulation noted in buying bituminous for future when supplies are fairly easy. More bad coal received. New retail anthracite prices out following freight-rate jump.

Bituminous—Dealers in soft coal here utterly fail to offer any adequate explanation of the lack of active seeking for coal supplies for the future on the part of many consumers. At present there is a fair supply of bituminous here as a result of diversions to the account of the fuel administrator of Maryland, augmenting the regular shipments, and while it is being absorbed there is none of the competitive rush for coal that might be expected after the shortage lessons of last winter and the idea being steadily pushed from Washington that conditions the coming winter are to be even worse.

A number of rejections from Tidewater Pool No. 18 were noted specially the past week. Some of the coal rejected is classed as "very poor." Little complaint, if any, is heard over the advance in freight rates of 45c. on line shipments of soft coal here or on coal for piers and delivery inside the Virginia Capes. Most people take jumps in prices and rates as a matter of course these days. There is a little less understanding of the need of making the outside the Capes increase 50c., however.

Anthracite—Facing necessity of adjustment of a freight-rate increase on prepared sizes of around 60 and 65c. since last April, the Baltimore retail coal men, after several conferences with the fuel administrative force in this city have issued a new retail sale schedule. In this schedule the coal men absorb 15c. of advance on prepared sizes and the public 45c. of the advance of from $2 to the new rate of $2.60. The freight-rate advance of 50c. on pea coal, or from $1.60 to $2.10, is absorbed by the coal trade, as that fuel, known as poor man's coal, remains at the old April schedule price. There are no changes in peck and bushel sale rates either, and this is the more noteworthy as there has been no advance in these small sale lots since last winter. The coal men here are complaining more about lack of ability to get coal than anything else. They admit that many consumers who placed orders last April and May, and whose coal has not been delivered, will be disgruntled over the fact that they will have to pay the new delivery price. The new retail anthracite schedule for Baltimore is as follows:

2240 Lb. to the Ton	Ton	½ Ton
Hard White Ash:		
No. 1 (Broken)	$10.75	$5.55
No. 2 (Egg)	10.45	5.40
No. 3 (stove)	10.70	5.50
No. 4 (chestnut)	10.80	5.55
Pea coal	8.95	4.65
Buckwheat	8.60	4.45
Lykens Valley:		
No. 2 (egg)	11.15	5.75
No. 3 (stove)	11.55	5.95

Prices for half tons are net.

A discount of 25c. per ton for cash.

Bagging, trimming and all labor in putting away coal to be charged at actual cost.

Lake Markets

PITTSBURGH

Heavy production shows magnitude of consumption. Steel industry's requirements heavy. Market narrow.

The record production of bituminous coal in the last three weeks and the fact that coal has not become plentiful, emphasizes the statement that coal requirements are altogether unprecedented.

Lake shipments are not causing any particular trouble, the movement proceeding rather smoothly and with indications that the amount permitted for the lake season, 4,000,000 tons for Canada and 24,000,000 tons for domestic ports, or 28,000,000 tons in all, will be provided without any great difficulty.

There is some stocking of coal, and perhaps a trifle more than a month ago, but all the testimony is that the stocking is proceeding much too slowly to suggest that the prospective difficulties of next winter are being safeguarded against. The by-product coke plants in particular frequently experience difficulty in getting enough coal for current consumption and are accumulating but little of the large reserves they would like to have for winter. The market is narrow, with open transactions representing but a small volume; and most of the transactions are in the form of allocations. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to regular brokers.

BUFFALO

Still predicting big winter shortage. Not much change in trade, except that anthracite is hardly so plenty. Some jobbers are doing well. Lake shipments fairly good.

Bituminous—The situation does not change much except that all predictions agree in looking for a shortage next winter quite as large as last, no matter what else happens. Whether the one report is an echo of another is hard to say, but the effect is seen in the increased effort to stock up. If there is a consumer next fall with empty storage capacity he will be reckoned either foolish or unfortunate. As it is now, all but the more isolated districts are able to get more coal than they need, and the rule is that they are making the most of it.

Jobbers as a rule do not find their business improving, but at the same time the more active and reliable are selling a liberal amount of coal. They do not claim to know how they get hold of the coal, but they either manage to stand pretty close to certain operators or they have a large amount of buying territory on their lists. It will not answer to stand still these days and let business come to you, for that will never happen.

Territory dependent on Buffalo for most of its coal is now pretty well taken care of. Canada, as a rule, has enough and New York state is fairly well taken care of; but the gateways to New England are pronounced too small for its needs. North of tidewater they are Poughkeepsie Bridge, Albany and Mechanicville.

The latest fixed prices are not well worked out yet, but at least certain leading jobbers are billing at $4.75 for thin-vein Allegheny Valley, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine-run and $3.95 for Pittsburgh slack, all per net ton, f. o. b. Buffalo.

Anthracite—The supply locally continues to run down. Shippers as a rule agree that there is nothing out of the ordinary about that, for they are sending all of their surplus up the lakes, and they will continue to do so all summer if a supply is laid down at upper lake ports sufficient to carry that territory through.

If Buffalo is suffering at all, it is because more anthracite is going east and to the army camps than we can well spare. When the lakes close in early December the amount going into that trade, if diverted entirely to this section, would meet all needs, but it is likely that New England and perhaps some other eastern districts would claim a part of it. The county administrator is warned by the state administrator that too much anthracite is going for steam making.

The amount of coal loaded for lake shipment for the week was below the recent average, being 98,750 net tons, of which 58,500 tons were loaded for Duluth and Superior, 20,200 tons for Chicago, 8000 tons for Sheboygan, 7600 tons for Green Bay, 3000 tons for Houghton and 1450 tons for Portage.

Freight rates remain at 48c. for Duluth, 50c. for Sheboygan, Green Bay, 60@65c. for Chicago and 75c. for the Portage lake ports of Houghton and Portage.

CLEVELAND

Ohio mines close, making further cuts in receipts. Local coal interests predict winter famine, being unable to place contracts. Fuel administration seeks old railroad lumber to aid domestic fuel supply. Lack of cars cuts week's supply 39 per cent.

Bituminous—Turn of the month has not brought any improvement in the coal situation in this market. Car shortage is given as the basis for the absence of normal supply of coal at this time, and although steps toward placing the situation before the Federal Railroad Administration are being considered, it is admitted there is no suggestion to offer, so far, to remedy this deficiency. The extreme car shortage has caused some mines in Ohio to close during the last week or so, and hundreds of miners are actually in danger of starving, the local trade has been informed. This combination presages a coal famine even worse than that of last winter. Already the production, as it will affect Cleveland, is 75 per cent. of normal, because where mines, even though slowing down, still are operating, they have much less labor than in times before the war. The local situation is especially critical, because, unlike other centers, there is practically no contracting ahead. To such concerns here, which have not contracts, mines are refusing to supply coal. With the priority orders now in effect, those consuming firms most essential to Government service are now getting the big supply of bituminous coal. The steel mills here are not able to put out as much product as they might if both car and labor situations were more normal. The latest report from the local offices of the Pittsburgh Vein Operators Association, of which D. F. Hurd is secretary, shows a shortage of coal of 39 per cent., or approximately 100,000 tons, due to the insufficient car supply, which is 2341 cars. More than 17,000 additional tons has been lost due to mine disability, labor shortage and the like.

Anthracite—Because most of the anthracite coal passing through Cleveland is being shipped up the lakes, and practically none consigned to Cleveland, receipts here are almost nil; and there is no indication the situation will be improved this month.

Lake Trade—Manning of 25 vessels for lake coal trade was completed this week, but this is not expected to help much unless receipts are increased. The lake schedule out of this port called for 4,000,000 tons, but only 3,500,000 were shipped, latest figures will show. Many boats have left with light cargoes, for although there were fifty vessels, there was not enough coal to distribute among them. Shipments for the last week were something more than 800,000 tons, but the normal movement for this period should be 1,000,000 tons each week. The amount fixed for July is 4,500,000 tons. It is admitted the lake trade has loosened up considerably in the last few days, so that the Fuel Administration's plan to get coal into the Northwest is working out well.

DETROIT

Inadequacy of supply continues to handicap early buying. Lake shipments make little gain.

Bituminous—Coal is not yet coming into Detroit as freely as jobbers and wholesalers say is necessary to assure a sufficient supply for the city's needs later in the year. The movement in June was disappointing to dealers who had hoped the month would give a strong impetus to the establishing of reserves not only among users of steam coal but in the yards of retail dealers as well.

Shipments received during the month, according to estimates of some of the jobbers, represent an aggregate little if any greater than the amount of supply necessary to fill current requirements. Complaint is heard that the supply of domestic stock is conspicuously deficient in quantity, while mine-run constitutes the larger bulk of the receipts, other sizes, including slack, reaching the city only in moderate amount.

Restoration of amicable relations has taken place between the Michigan fuel administrator, W. K. Prudden, and Detroit business interests represented by the Detroit Board of Commerce.

Anthracite—Detroit is not yet receiving anthracite in any substantial amount. Much of the time during June receipts were under 40 cars a day. Household consumers are unable to get orders filled but are unwilling to stock up with bituminous.

Lake Trade—Movement of coal over the lake routes in June did not equal expectations. Shipments were augmented for a few days early last week, but before the end of the week slumped off again with a light movement from the Pittsburgh district. Heavier shipments will be necessary this month to maintain schedules and supply the Northwest before winter sets in.

COLUMBUS

Strong demand characterizes every branch of the coke trade in Ohio. Mining operations in certain districts have been improved.

The coal trade in Ohio during the past week has been active in every way. Demand for steam, domestic and lake tonnage is still strong, and there is still a scarcity of available stocks. The lake trade is being rushed as rapidly as possible and steam users are increasing their storage. On the whole the tone of the market has been active in every way, and prospects are for a continuation of the strong demand from every locality.

The domestic trade is still one of the important departments of the industry. Dealers are clamoring for stocks and have placed orders both for immediate and deferred delivery. Retail stocks are quite light and most of the dealers are operating from hand to mouth. Retail prices will be changed to take in the new freight rates and also the advances in most Ohio districts which were announced effective June 29. Dealers are busy making deliveries, as users are now anxious to secure their stocks for the coming winter. Pocahontas is quite scarce and only small consignments are arriving in the local trade. Some West Virginia splint is available. Pomeroy Bend and the Hocking Valley are supplying the largest tonnage.

Steam demand is also good and the larger consumers especially are making frantic efforts to increase their surplus stocks. Many of the users have all available storage space occupied. The smaller users are following the example of the larger consumers and are also stocking up to guard against an emergency. Fuel regulation is holding down orders in certain places. Railroads are taking a goodly amount for the operation of trains.

Lake trade is strong, and a priority order is now looked for in order to stimulate lake movement. So far the lake trade has not been up to expectations, and a shortage of more than 1,000,000 tons is reported from the head of the lakes. Vessel movement is active and fewer bottoms are going to the upper lake region light.

Lake prices are firm at the new levels announced by the Federal Fuel Administration several weeks ago.

CINCINNATI

Record-breaking deliveries are under way, facilitated by improved car supply and good weather. Labor conditions present the only probability of trouble at present.

Loadings at West Virginia mines during the past week broke all records, indicating the decided improvement which has taken place in the matter of car supply and the satisfactory condition of the supply of labor for the time being. Some deliveries of new open coal cars are reported to have been made, rather unexpectedly early, considering the fact that the orders for the equipment were placed only a short time ago; and as it is obvious that deliveries will increase as time goes on, it is evident that the shortage of rolling stock, which contributed so largely to the distressing conditions of last winter, will be largely remedied before cold weather again sets in. The movement of coal to the lakes, under the system of distribution now in force under the orders of the Fuel Administration, is very heavy and bids fair to care for all of the requirements of the Northwest without difficulty. In fact, if the threatened shortage of labor does not develop acutely, the effective coöperation of the railroad and fuel branches of the national administration promises to take care of the Nation's extraordinary fuel requirements in an astonishingly efficient manner. With a higher percentage of domestic requirements than ever before taken care of by summer storage, it will be possible to concentrate more generally on the industrial supply. The trade is becoming more and more optimistic over prospects in this respect.

LOUISVILLE

The domestic stocking demand continues strong, and is taking care of practically all of the coal received from both the eastern and western Kentucky fields at this time. Steam demand about normal, with production generally light.

Unless coal production increases in both the east and west Kentucky fields, even Louisville, located between two considerable fields, will have trouble in securing coal supplies this winter. At the present time no surplus stocks are being secured, while increased consumption is shown on every hand. The new Government powder plant at Nashville, Tenn., is expected to take a large percentage of the production of that district and general plants are operating on Government contracts and must be supplied.

During the past week it was announced that the Government would erect a large powder plant at Louisville in addition to the one at Nashville, and it was further announced that a new artillery cantonment with a capacity of 30,000 men would be erected at West Point, Ky. These two new developments alone will take a considerable volume of coal, and increase the necessary tonnage, whereas production in both the east and west Kentucky fields has been steadily decreasing due to the shortage of labor.

BIRMINGHAM

Production being speeded up to some extent. Supply to meet domestic and steam requirements still short. Market very active for all grades.

Alabama mines made some progress in the prime essential of increased production during the past week, according to information gathered from the producers and distributing agencies, and the opinion is held that continued improvement will be shown from now on.

There is still a distinct shortage in receipts of domestic coal by local dealers to care for the orders now in hand, practically no stocking having been accomplished in respect to the higher grades of coal. The Montevalle Mining Co., the largest producer of strictly domestic fuel and the only company which has contracted its output to any extent, is now installing six longwall conveyors in its mines at Aldridge, which is expected to materially increase the output. Much of this coal is being sought in North Georgia points, which formerly depended on Tennessee and Kentucky fields for the better grades of fuel.

The fuel situation with the railroads is somewhat easier than before for some weeks, and some accumulations are reported in storage bins, which will probably enable a reduction in priority requirements and provide a more liberal supply for industrial plants. The Southern Ry.'s advertised requirements for some 1,800,000 tons for the year ending June 30, 1919, are reported to have been about two-thirds provided for in tentative agreements. Other contracts for railroad fuel are being made as the old ones expire.

The sharp increase in coal rates from the fields supplying the local market are being commented upon generally and some adjustments are expected.

Coke

CONNELLSVILLE

Market quiet. More byproduct coke in prospect. Connellsville production steady.

There has been no further contracting for furnace coke, following the few contracts hitherto reported. The great majority of the furnace-coke contracts are for the whole year, requiring no mid-year negotiations. In the case of foundry coke quite a number of contracts expired June 30, and many of these have not been renewed, so that there will be more prompt business done than formerly. Foundry coke is in only moderate supply, but on the whole it is easier to buy foundry coke than furnace, as operations are proceeding in such a way that a rather high proportion of 72-hour coke is made; and the operators prefer to make foundry coke, as there is no difficulty in securing the full $7 price, as compared with $6 for furnace.

There is considerable speculation as to what will occur in beehive-coke production in the Connellsville region as the new byproduct ovens in the Central West get into operation, using Connellsville coal quite largely, although not exclusively by any means. That there will be some reduction in Connellsville coke output seems probable. Thus far, however, there has been no material change, although the American Steel and Wire Co.'s new plant of 180 ovens at Cleveland is now in nearly full operation, having made its first coke early in May, while last week the first battery, 128 ovens, of the Carnegie Steel Co.'s Clairton plant was put in operation. Four more batteries will follow in the next two or three months, while six more will come some time next year. At the first of this year the existing byproduct coking capacity was approximately 500,000 tons a week, according to the individual works rating, but experience has shown that from a combination of causes the actual production runs 88 to 90 per cent. of capacity, this having been the testimony of the Geological Survey's weekly reports for more than two months past. Capacity by some time in September should have risen to about 640,000 tons weekly, promising an actual output of about 575,000 tons a week.

Furnaces have been endeavoring to accumulate some surpluses of coke to carry them over the curtailment in coke movement that invariably occurs at Independence Day, and have been fairly successful. The market remains quotable at $6 for furnace, $7 for foundry, 72-hour selected, and $7.30 for crushed, over 1 in., per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended June 22 at 344,950 tons, an increase of 1980 tons. For about 10 weeks past production has averaged 341,000 tons a week.

Buffalo—The trade drags a good deal, for though it is not so difficult to buy coke it is a hard matter to get it delivered. The late advance of freights from the Connellsville district from $2 to $2.60 would not be a hindrance if the cars could be had, for any rate would fail in that respect. The furnaces are kept going somehow. What they pay for coke is not known to the jobbing trade, for it gets none of that business; but the regulation of $7 and $6 for the best grades is still in force, to which must be added the $2.60 freight and no middleman's profit. Considerable breeze coke is selling for steam making at about $2.75 net, oven price. Iron ore receipts are large, being 308,813 gross tons for the week. Cars for shipping out ore are so scarce that it piles up badly at the docks.

Middle Western

GENERAL REVIEW

Demand in excess of supply. Will be shortage in anthracite. Production hampered by car shortage.

The demand at the present time for both steam and domestic coals from the producing districts of Indiana and Illinois is greatly in excess of the supply. Screenings and mine-run coal from the Springfield and Standard districts of Illinois are selling strong. This is a decided change from a week back, when these coals were to be had at a substantial decrease from the Government price. This condition is brought about as much as anything by the recent ruling of the Fuel Administration, which allows both Illinois and Indiana screenings to go into the southern part of Michigan. In addition, a number of factories in the Chicago district have become alarmed over their supply and have endeavored to place orders for extra coal so that they will go into the winter months with a supply on hand sufficient to run them from one to two months at least. The difficulty they are encountering is that they can find but few operators to book their orders. The producers who have their regular business are only able to give them enough coal to keep them going from week to week. High-grade screenings and steam coals from the southern part of the state are hard to get. This is equally true of the Springfield and Standard districts. It is rumored that one of the large western railroads having mines in the central part of Illinois is about to close its mines for a short period and purchase its coal on the open market. This rumor has given a decidedly bullish tinge to a market already strong.

The retail dealer is now fairly awake to the problems to be faced next winter, and in a number of cases dealers have hired vacant lots or available property near them and on this property are piling up mine-run, screenings and 2-in. lump. They have come to the conclusion not only will there be a shortage of anthracite, but in addition there will not be enough high-grade southern Illinois domestic coal to go around. The demand for domestic coals is keeping up as strong as ever. Retail dealers are trying to place orders with their various sources of supply, and in case orders have been placed they are trying to have these orders increased. The buying public is wakening up to the situation and trying to get under cover.

The tonnage in the states of Indiana and Illinois will not be up to its maximum for this period, as production has been hampered by car shortage and lack of miners to produce the coal. The car situation is just about the same, but the labor situation is getting worse from week to week.

CHICAGO

A slight fall in the volume of retail orders was noticeable toward the end of the week.

The disposition on the part of domestic coal users to order their winter supply now continues, but with a marked decrease the last three days, to be attributed, perhaps, to warmer weather. Retailers are loaded up with orders for some time to come, so that this condition gives no cause for alarm.

There is practically no anthracite in the Chicago market, certainly none which is not covered by long standing orders.

The new ruling of the Railroad Administration to the effect that freight bills must be met on a cash basis has caused dealers with limited capital to insist on cash on delivery. This, also, has probably been one cause of the let-up in orders from domestic consumers.

All grades of coal continue to be taken by large consumers, as rapidly as they are received, with the exception of certain grades of screenings, but stocks of those are not accumulating to any great extent.

Quotations in the Chicago market are as follows, per net ton f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La-Salle, Bureau and Will.
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40

MILWAUKEE

Official anthracite price schedule received from Washington. A busy week in coal circles. Coal administration force increased.

Milwaukee has experienced what may properly be termed a coal week, because of a bunching of notable events in connection with the trade; namely, the announcement from Washington of the new local price schedule for anthracite coal; the return of State Fuel Administrator W. N. Fitzgerald from the national capital; the naming of Prof. Stephen W. Gilman, of the University of Wisconsin, as his special assistant; the appointment of C. A. Cahill, of Milwaukee, as state administrative engineer, and a two-day session of the Illinois and Wisconsin Coal Dealers' Convention.

Anthracite prices are considerably higher than the prevailing rates at this time last year. Egg is rated at $10.60, stove at $10.82 and nut at $10.91. No prices have been named on buckwheat, pea and broken coal. During 1917 anthracite prices increased 10c. per ton for three months. This year the entire increase for three months will become effective Sept. 1 and remain in force indefinitely. This ruling is applied to encourage summer buying. The prices named apply to coal delivered at the curb. The cost of carrying in is placed at 50c. per ton and 25c. for less than ton lots.

Wisconsin has also been accorded more coal from southern Illinois and an increase of 8 per cent. in the previous allotment of buckwheat and pea anthracite. It developed that the schedule 86 per cent. anthracite supply covered the larger sizes only. Surplus buckwheat and pea will be sent to the state during the course of the season.

A vigorous campaign in the interest of increased consumption of bituminous coal is to be prosecuted from now on. Mr. Cahill, the new administrative engineer, will devote his attention to devising ways and means for saving fuel in manufacturing plants throughout the state. Counties in the extreme northern and northwestern parts of the state, where wood is abundant, will receive little or no coal.

Stephen D. Balliet, of Appleton, Wis., was chosen president of the Illinois and Wisconsin Retail Dealers' Association; E. C. Streeter, of Grand Fork, Ill., vice-president; O. S. Dodge, of Monroe, Wis., treasurer, and Peter Beck, of Harvey, Ill., and C. H. Hill, of Beloit, Wis., directors. I. L. Runyan, of Chicago, is secretary.

Chippewa Falls, Wis., is now purchasing soft coal for $4.95 per ton delivered in bins. The city contracted for 475 tons at $2.85 at the mines, but this price was reduced on order of the Government.

Coal receipts by lake at Milwaukee continue slow. Since the last report 7500 tons of hard and 62,858 tons of soft coal have reached the docks, making the record since the opening of navigation up to the present time 152,235 tons of hard and 799,541 tons of bituminous.

ST. LOUIS

An unusually good market, contrary to expectations. Carterville coal hard to secure. Other coals somewhat easier and Standard inclined to be weak. Steam sizes not moving free. Transportation better. Car supply poor.

The local situation is encouraging from the fact that the demoralization that was expected to follow the higher rates in view of the large amount of coal put in storage under the low rate did not materialize. Locally the domestic demand has fallen off some, but the orders on the books of the retailers is sufficient to last them for two or three months. The principal trouble locally is the fact that users of high-grade fuels are unable to secure them and are undecided what to take as substitutes. Up to the 27th of May the retailers of St. Louis had booked about 40,000 tons of anthracite coal, none of which will be delivered. To replace this will require about between 90,000 to 100,000 tons of soft coal. These orders have not yet been placed.

It is expected that about 25,000 to 30,000 tons of coke will be available from the local plants in the next eight months, which will take the place to some extent of hard coal, but this demand upon Government instructions for coke distribution. If there are manufacturing plants and public utilities that must have this coke then the domestic consumer will not get it.

Indications are now that there is going to be unusual activity in the retail market in the next three months, and to such an extent that the retailers will not be able to handle the situation with the volume of orders now on hand.

The Carterville situation this week shows a somewhat disappointing tonnage. The car supply has been exceptionally poor, and in a general way there seems to be a decrease in the tonnage available for domestic shipment. It is expected, however, after July 1 there will be a better supply for domestic shipment on account of rumors that the Government has an order prohibiting the railroads from taking this coal for railroad purposes.

In the Mt. Olive field the car supply has been poor the past week, but the tonnage of coal produced is about equal to the demand.

In the Standard field the car supply has been unusually bad and there have been idle days this past week caused by the men laying off to celebrate the departure of the men in the draft. Other mines have been idle on account of no orders.

There is not a good market for Standard coal.

The steam market is unusually weak in places. There is, however, a feeling that this market will improve in the next ten days or two weeks.

There are no Eastern or Arkansas coals moving in.

The St. Louis Fuel Committee established new prices for retail as follows, effective July 1:

Carterville, $6.20; Duquoin, $5.95; Mt. Olive, $5.70, and Standard, $5.45. This is sidewalk delivery, two tons or more.

The price on domestic coke was fixed for June deliveries at $12.50; July, $12.75; August, $13. This on both gashouse and by-product.

There has been no change in the mine price from last week other than that Standard screenings are worth from $1.30 to $1.50 on account of restrictions and Standard 2 in. lump is quoted at from $2.25 to $2.40, with egg and nut at the same figure. Other coals are bringing the Government maximum.

The prevailing market is, per net ton, f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....

* These prices include the freight charge from the valley to the Pittsburgh district. † Delivered Tidewater, New York.

STRUCTURAL MATERIAL—The following are the base prices, f.o.b. mill, Pittsburgh, together with the quotations per 100 lb. from warehouses at the places named:

	Mill, Pittsburgh	New York—Current	New York—1 Year Ago	St. Louis	Chicago
Beams, 3 to 15 in.	$3.00	$4.245	$5.25	$4.27	$4.27
Channels, 3 to 15 in.	3.00	4.245	5.25	4.27	4.27
Angles, 3 to 6 in., ¼ in. thick	3.00	4.245	5.25	4.27	4.27
Tees, 3 in. and larger	3.05	4.245	5.25	4.27	4.27
Plates	3.225	4.745	9.00	4.52	4.52

BAR IRON—Prices in cents per pound at cities named are as follows:

Pittsburgh	St. Louis	Denver	Birmingham
3.50	4.17	4.05	4.38

NAILS—Prices per keg from warehouse in cities named:

	Mill Pittsburgh	St. Louis	Denver	Chicago	Birmingham	San Francisco	Dallas
Wire	$3.50	$4.50	$4.85	$4.32	$4.25	$5.95	$4.75
Cut	4.00	5.40	.....	4.47	....	6.40	.....

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots, together with the warehouse prices at the places named:

	Pittsburgh Current	Cincinnati	Chicago	St. Louis	San Francisco	Birmingham	Denver
Standard railroad spikes ⅝-in. and larger	$3.90	$6.00	$4.50	$5.30	$6.70	$5.30	$5.00
Track bolts	4.90	8.90	5.50	Prem.	8.00	8.00	6.00
Standard section angle bars	3.25	....	4.45	Prem.	5.15	....	4.30

COLD DRAWN STEEL SHAFTING—From warehouse to consumers requiring fair-sized lots, the following discounts hold:

Cincinnati	Cleveland	Chicago	St. Louis	Denver	Birmingham
17½%	List	+10%	+10%	+35%	+30%

HORSE AND MULE SHOES—Warehouse prices per 100 lb. in cities named:

	Mill Pittsburgh	Cincinnati	Chicago	St. Louis	Denver	Birmingham
Straight	$5.25	$7.50	$6.50	$6.25	$8.00	$7.50
Assorted	5.40	7.50	6.50–7.00	6.40	8.25	7.75

Cincinnati—Horseshoe nails sell for $4.50 to $5 per 25-lb. box

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	New York—Current	New York—1-Month Ago	New York—One Year Ago	Chicago	St. Louis	San Francisco
4 in.	$64.35	$64.35	$68.50	$64.80	$63.00	$76.00
6 in. and over	61.35	61.35	65.50	61.80	60.00	73.00

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	Pittsburgh—Current	Pittsburgh—One Year Ago	Chicago—Current	Chicago—One Year Ago
Standard Bessemer rails	$57.00	$38.00	$67.00	$38.00
Standard openhearth rails	55.00	40.00	65.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	58.00	*3.135 (100 lb.)	53.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	57.00	*3.09 (100 lb.)	54.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	53.00	*3.00 (100 lb.)	52.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$30.80	$33.00	$34.00
Stove plate	22.50	25.00	19.00
No. 1 machinery cast	34.00	29.00	21.50–22
Machine shop turnings	15.30	17.50	19.00
Cast borings	15.30	17.50	18.50
Railroad malleable cast	30.30	29.00	25.50–26

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.18	$0.17

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	15c.	14c.	15c.
Hollow	24c.	25c.	..

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Black	Galvanized	Iron Inches	Black	Galvanized

Underwriters' 2½-in	75c. per ft.
Common, 2½-in	40%

Air

	First Grade	Second Grade	Third Grade
¾-in. per ft	$0.55	$0.30	$0.25

Steam—Discounts from list

First grade 30% Second grade 30–5% Third grade 40–10%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	40+5%	35%
Denver	35%	30%
Birmingham	30%	35%
Chicago	45%	40%
Cincinnati	40—10%	40%

RAWHIDE LACING—40—5% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.99
Asbestos for high-pressure steam	1.76
Duck and rubber for piston packing	1.10
Flax, regular	.99
Flax, waterproofed	1.21
Compressed asbestos sheet	1.10
Wire insertion asbestos sheet	1.30
Rubber sheet	.66
Rubber sheet, wire insertion	.99
Rubber sheet, duck insertion	.55
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.21
Asbestos wick, ½- and 1-lb. balls	.75

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20%
Galvanized cast steel rigging	List
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	5%

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅝-in., 8 ft.; ¾-in., 6; ⅞-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0.34	Birmingham	$0.38
New York	.30	Denver	.35½
Cincinnati	.33¼	Kansas City	.34
Chicago	.34	Seattle	.34
St. Paul	.34	St. Louis	.34
San Francisco	.32	Los Angeles	.35

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING

Pipe Size	Standard List Per Lin. Ft.	Price Per Lin. Ft. One Year Ago

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.27	New Orleans	$0.385
Buffalo	.17	New York	.245
Chicago	.27	Philadelphia	.23
Cincinnati	.23	St. Louis	.34
Cleveland	.17	St. Paul	.495
Denver	.99	Pacific Coast (all rail)	1.25
Kansas City	.59		

Note—Add 3% transportation tax.

COAL AGE

Volume 14 New York, July 13, 1918 Number 2

Traveling Toward Daylight

By FLOYD W. PARSONS

THE coal industry is rapidly progressing toward a solution of many of its difficulties. It is unwise, however, to assume that a few weeks of record coal shipments indicate that we are finally out of the woods. After all is said and done, the fact remains that we are a volatile people, too prone to have thumbs up today when only yesterday we were demanding a sacrifice.

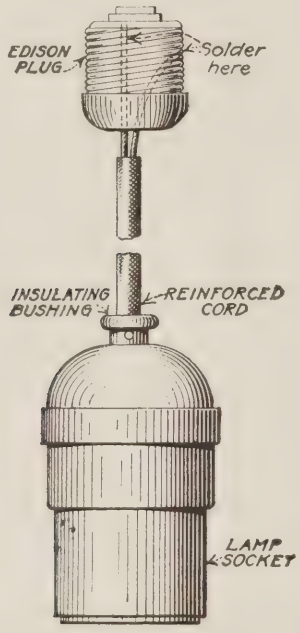
About the only constant thing in the world is inconstancy. Our appetite calls for steak, and when we find we can't have it, we conclude the restaurant man is a robber and is trying to make us eat fish because his profit on this food is greater. When the shoe that pinches is on our own foot, we yell like "blue blazes"; but when some other poor devil comes hobbling along, we contend he is either a darned fool for wearing such a shoe, or a blamed traitor for whimpering.

When the house or the office is cold in January, we are sure Dr. Garfield is an incompetent, and wonder how under heaven the President could have selected him to administer the coal business; but when the warm winds of July fan us into forgetfulness, we are astonished that anyone should consider coal a prime necessity of life.

Let us try and remember that the guns on the battlefront in France are belching forth their missiles of death right now, and consuming thousands of tons of American coal. Let us rejoice that our splendid shipbuilding forces were able to launch so many ships on the Fourth of July; but we must not forget that when those ships slid into the water they represented the potential power and the actual consumption of 1,035,000 tons of coal.

We are building some new style tanks, and we hope to send them across "No Man's Land" in such numbers that the Hun defences will crumble before the onslaught; but let us remember that each big tank we build will consume 190 tons of coal. Every Liberty motor that goes into an airplane has used up in excess of a ton of coal, and we propose to manufacture these engines in thousand lots.

Never before have the shipments of coal been so large as in recent weeks, and the comment on every side is—"At last we have struck our gait." We should smile and be happy over the fact that we are breaking records, but let us not foolishly assume that our troubles are at an end. The railroads have hardly started to move crops, and they are not combating the floods, snow and ice of winter. If we cannot make headway now, we will present a sorry spectacle six months hence.



The coal situation is serious. We have fewer miners than a year ago, not many more cars and very little coal in storage. However, there is no reason to feel despondent or to slow up in our fight. No way is impassable to courage. The Fuel Administration is composed of capable, patriotic men, who are giving unselfishly the best that is in them. Great progress has been made toward the orderly and effective control of an immense industry of vital importance. Let us stand shoulder to shoulder, not a few of us, but everyone, and let us have faith one in another and see if thus united we cannot give the Huns such a licking that succeeding generations of Germans will curse the infamy of the Hohenzollerns.

IDEAS AND SUGGESTIONS

Makeshift Extension Cord

By L. M. Beck

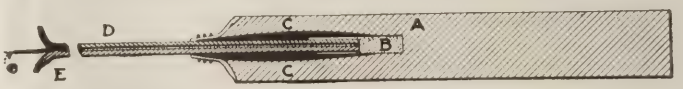
When an extension cord must be assembled and no extension plug is available, the cord can easily be arranged as suggested in the accompanying illustration. The length of reinforced lamp cord is first made up into a lamp socket which is provided with an insulating

SHOWING ARRANGEMENT OF EXTENSION CORD

bushing, following the usual practice. Then, instead of using an attachment plug, an old Edison fuse plug can be made to serve, as suggested in the drawing.

The mica window should be taken out of the old fuse plug; then one of the conductors of the cord is soldered to the screw shell and the other to the button contact at the end. Where refillable fuse plugs are used, screw binding posts are provided in them whereby the lamp cord conductors can be electrically connected to the screw shell and to the contact button without the use of solder.

Firing Wet Holes



By T. F. Price

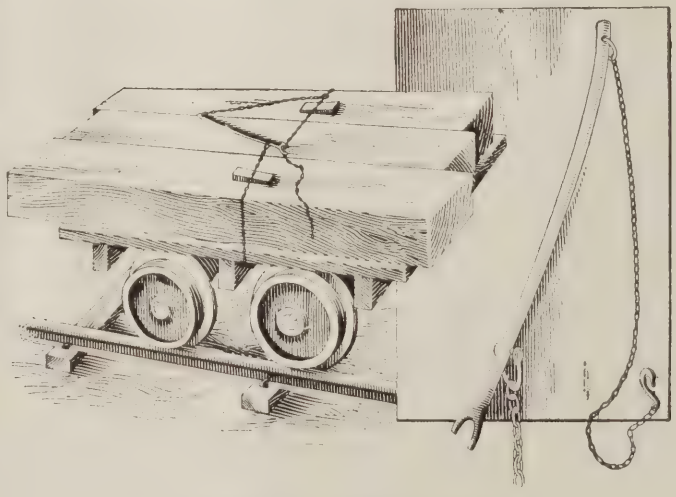
San Antonio, Texas

The accompanying illustration shows a method that I have used quite successfully in firing wet holes. I trust this method may be of service to others. Referring to the illustration, *A* is a stick of dynamite, *B* is the detonator and *C* is a paraffine seal. In preparing this cartridge the covering on the end of the stick of dynamite is first opened carefully. Next, with a stick of suitable size, a hole is made in the explosive to a depth equal to at least twice the length of the detonator.

The fuse should now be trimmed in order to be sure that the end entering the cap is perfectly dry. This end is next inserted and the detonator carefully crimped. The paraffine is now applied, being carefully pressed firmly around the cap and fuse. For this purpose, the paraffine may be brought to the proper consistency by kneading and working in the hand.

The detonator may now be inserted in the cartridge, the wrapping being securely tied around the fuse. The

METHOD OF FIRING WET HOLES



other end of the fuse, as shown at *E*, should now be split, exposing the core *e*. When the charge of explosive is properly put in place and tamped, all that now remains to be done is to light this core *e* and retire to a safe distance.

I have repeatedly used this method when firing charges submerged under 15 ft. of water and had uniformly good success.

Device for Binding Timbers on a Truck

By C. T. Rice

In the accompanying sketch are shown the details of a useful device for binding round or square timber and lagging securely on a timber truck. It consists of a lever made of a slightly bent piece of 1-in. steel, through which two holes are punched, one about a fifth

DETAILS OF TIMBER BINDER

of the length of the rod from one end, which end is fashioned into a claw. The other hole is punched at the other end of the rod.

A clevis is attached to the hole near the claw, as shown. To this is connected a ⅜-in. binding chain, long enough to go around the load of timber and back

up under the truck. The other hole is used as a point of attachment for a small chain the same length as the binding lever. On the end of this short chain is a hook which can be made to engage some link in the binding chain.

In using the device, the binding chain is passed around the load and the timber truck and then brought back on top, so that it can be gripped by the claw in the end of the lever. The free end of the lever is then pulled back as tightly as possible, and the fastening chain hooked to a link in the binding chain, holding everything tight. When the truck is being used to haul plank lagging which is covered with ice, as is often the case in winter, it is well to drive a wedge between the chain and the top planks of the outer rows in the load, for in that way the chain can be more snugly gripped to the slippery planks.—*Engineering and Mining Journal.*

Apply Your Thought

By Leigh Mitchell Hodges

To a man marooned on a desert island, a safety pin might mean more than a million dollars.

Money is useless if it can't be exchanged for something you need or want.

Thought is more powerful than money, because it not only mothers the making thereof, but determines the spending.

Yet unapplied thoughts are as worthless as dollars that cannot be used.

On the walls of one of the world's biggest factories are scores of placards bearing in giant letters the word "THINK." The founder and owner of this business says it is the one form of service he has had the hardest time getting, though willing to pay more for it than for any other.

Even those who think often waste thoughts through not applying them. Others never try cross-application—testing in some new field thoughts which already have proved profitable.

In a great industrial plant a certain man directs the manufacture of a standard product. Lately, new uses were sought for this. At one suggestion this man suddenly remembered he long ago had tried that same plan and found it practical.

Failure to apply his thought in the larger field had cost him self-advancement and sales profits.

"If twenty pairs of men's trousers can be cut out at one operation, why not apply the same cost-reducing plan to automobile parts?" was the thought-urge back of the biggest motor car business on earth.

It was simply cross-fertilization of brain power!

"If steam lifts a kettle lid, why won't it push a piston head?" was the mothering thought-force of every engine and dynamo today doing the world's work.

THINK—but don't stop there!

Don't rest with one successful application of your thought.

There may be two or ten Cinderellas whose feet will fit your glass slipper!

THINK—for thought is the ancestor of every action. But one thought may have many children of achievement.

Apply your thought in varying fields, and thus multiply your own profits and those of others.

And never let any thought pass untried—for this is one sure road to the sea of remorse, where dreams and hopes are drowned in the black waters of "It might have been!"—*Du Pont Magazine.*

Spending and Helping the Enemy

UNCLE SAM needs twenty billions of dollars or so this year for the war. What does Uncle Sam do with this money? He spends it just as you and I spend our money.

What does he spend the money for? For ships, guns, shells, clothes and food for the soldiers and sailors, and for many other things needed to carry on war.

What do you and I spend our money for? For houses to live in, food to eat, clothes to wear, and for many other things of greater or less use to us.

But some of the things we want are exactly the same things Uncle Sam wants, and some of the other things we want, while not exactly the same as the other things Uncle Sam wants, require, in order to be made, the raw material, labor and transportation facilities that are also required for making the further things that Uncle Sam must have.

Uncle Sam could not perhaps use your new suit. But he could have used the wool that is in it, the labor that fashioned it and brought it to market, and the transportation agencies that were necessary to carry it.

Hence, every time you buy something that you do not positively need you are selfishly withdrawing from service to Uncle Sam raw material and supplies, labor and transportation.

There is available only a certain amount of raw material of all kinds; labor can be pushed only to a certain limit, and beyond maximum capacity nothing further can be expected from the railroads.

Before the war, we used everything to cater to our own private needs. Now, about one-half of all that we can produce must be put aside for war purposes. If that is to be done—and it must be done if we are going to win—everybody must do his "bit."

We cannot eat our cake and have it too! We cannot insist upon eating and dressing and having a good time as before, and expect our Government to put up a winning fight. When we save, we stop competing with Uncle Sam—and with the boys in the trenches.

Better still, when we save and put our savings in Thrift and War Savings Stamps, we are saying to our boys in the trenches: "Here, boys, count on me. Here is food and clothing and medicine. If this is not enough, I'll do even better."

The best way to do "even better" is by joining a War Savings Society. Then in "our crowd," in "our shop," in "our office," we will learn to do without by all agreeing to do without the same things.

Motor-Driven Shaft-Hoist Installation

By R. P. HINES
Fairmont, W. Va.

THE purpose of this article is to give a somewhat detailed description of a comparatively large electrically operated shaft-hoist installation in the bituminous coal fields of West Virginia. Two sets of equipment are being installed, one at each of two separate mines, the shafts of which are about two miles apart. Although there is a slight difference in the depth of the two shafts, the two equipments are practically duplicates, so it will only be necessary to consider one of them in detail.

The depth of the shaft, from top of casing to bottom of coal, at which the equipment described operates, is 506.8 ft., while the travel from the sump rail to dump is 550.1 feet.

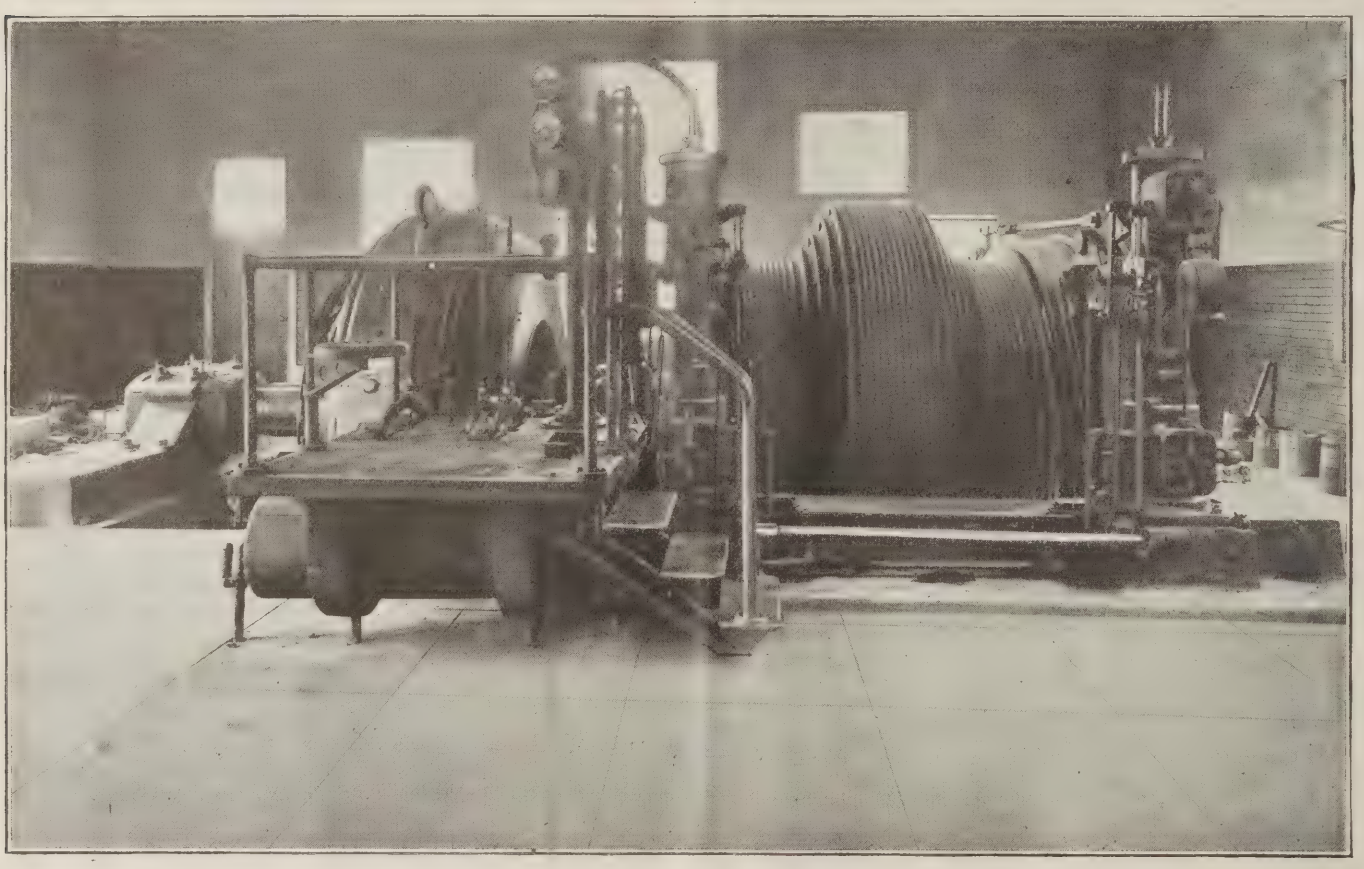


FIG. 1. GENERAL VIEW OF THE DIRECT-CONNECTED, ELECTRICALLY DRIVEN HOIST

The motor is direct-connected to the hoist, and the control and arrangement of the equipment is such that a practically constant input is taken from the transmission line, although the actual peaks on the hoist motor vary from a maximum of 1800 hp. to a minimum of 400 hp. negative. The hoist is fitted with one cast-iron, double cylindro-conical, tight-grooved drum, 8 ft. in diameter at the small ends, 11 ft. in diameter in the center and of sufficient face to coil 563 ft. of 1½-in. wire rope, allowing three full extra turns at each end of the drum for fastening. There are five active turns on each of the 8-ft. diameter cylindrical portions, five active turns on each of the conical portions, and 8.04 active turns on the 11-ft. diameter cylindrical portion. The shaft is of the double-compartment type, the loaded car and cage being hoisted in one compartment, while the empty car and cage are being lowered in the other. Two separate ropes are used on the single drum, being fastened at opposite ends, the one winding onto the drum at the top while the other is winding off the drum at the bottom, and vice versa.

The system is operated with the cages and the cars in balance, and on the slack-rope plan so arranged that the descending cage lands at the bottom as the ascending cage is coming into the dumping horns. The last 2.88 ft. of the hoist and dump is thus made "out of balance." The equipment is designed to hoist 3¼ short tons of coal per trip and to make 2½ trips per minute, operating on the following calculated cycle:

	Seconds
To strain down rope	2
Accelerating	6
Full speed running	5.82
Retarding	5
Dumping	5
Rest	0.18
Total time of trip	24.00

Fig. 4 gives the calculated duty curve based on this cycle of operation. The average hoisting speed is approximately 2500 ft. per minute, and the maximum hoisting speed is 3100 ft. per minute.

The hoist is driven by a 1400-hp., 550-volt, 90-r.p.m., direct-current, compound-wound, commutating-pole motor, the armature of which is pressed onto the same

shaft that carries the hoist drum. Two post brakes, either of suitable capacity for holding the load, are provided. These are of the air-actuated, dead-weight type. They are equipped with electrical solenoids for emergency application, and after being set may be released by levers on the operator's platform.

The electrical end of the equipment is operated on the Ward Leonard method of control combined with the Ilgner flywheel method of load equalization. By this system a flywheel motor-generator set is used for converting the incoming alternating-current power to direct current for operating the hoist motor. This unit consists of an eight-pole, 1000-kw., 720-r.p.m., 550-volt, separately excited, shunt-wound, commutating-pole, direct-current generator driven by a ten-pole, 600-hp., 720-r.p.m. (synchronous speed), 2200-volt, three-phase, 60-cycle, slip-ring, wound-rotor induction motor. A large steel-plate flywheel 8.75 ft. in diameter and weighing 30,000 lb. is connected to the motor shaft by a flexible coupling, while a 17-kw., 250-volt, compound-wound exciter is mounted on the same shaft. Fig. 3 shows this flywheel set and indicates clearly the relative positions of the different units.

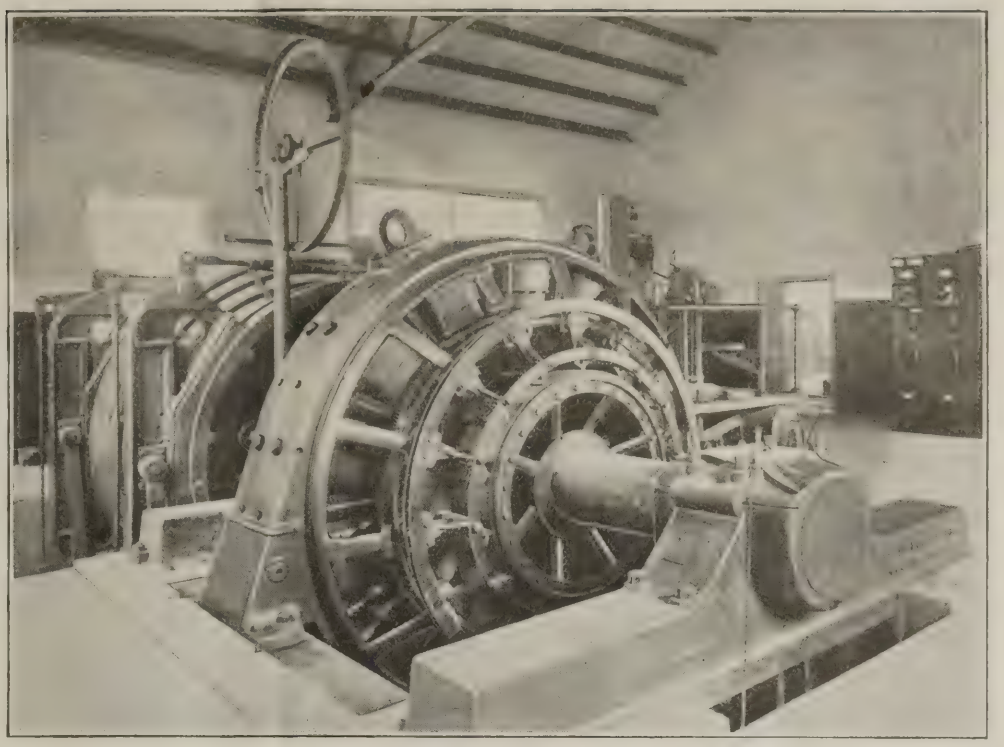

FIG. 2. MOTOR END OF HOIST

As the speed of the flywheel motor-generator set in the normal operation of the system must vary through a comparatively wide range, the direct-current exciter is designed for operation between 470 and 720 r.p.m.; and in order to maintain a constant voltage from this exciter within this speed range, a Tirrill voltage regulator is provided. This is mounted on the exciter panel, and in this way forms part of the switchboard equipment. The switchboard equipment provided for the installation comprises seven panels, as indicated by Fig. 6. These include an alternating-current incoming line panel; an alternating-current motor panel for the flywheel set; a direct-current motor panel and a direct-current exciter panel. The other panels are included for controlling a small bank of transformers for reducing the 2200 to 220 volts for the tipple motors; together with the required 220-volt feeder circuits, which also furnish power to the motor-driven air compressors used for obtaining the compressed air required for operating the air brakes of the hoist.

Power to operate the flywheel set is transmitted at 23,000 volts from the central generating station over a line approximately three miles long. The conductors of the line are carried on triangular laced steel poles, with some rectangular four-leg towers, on the long spans. A Siemens-Martin galvanized-steel strand ground wire is used.

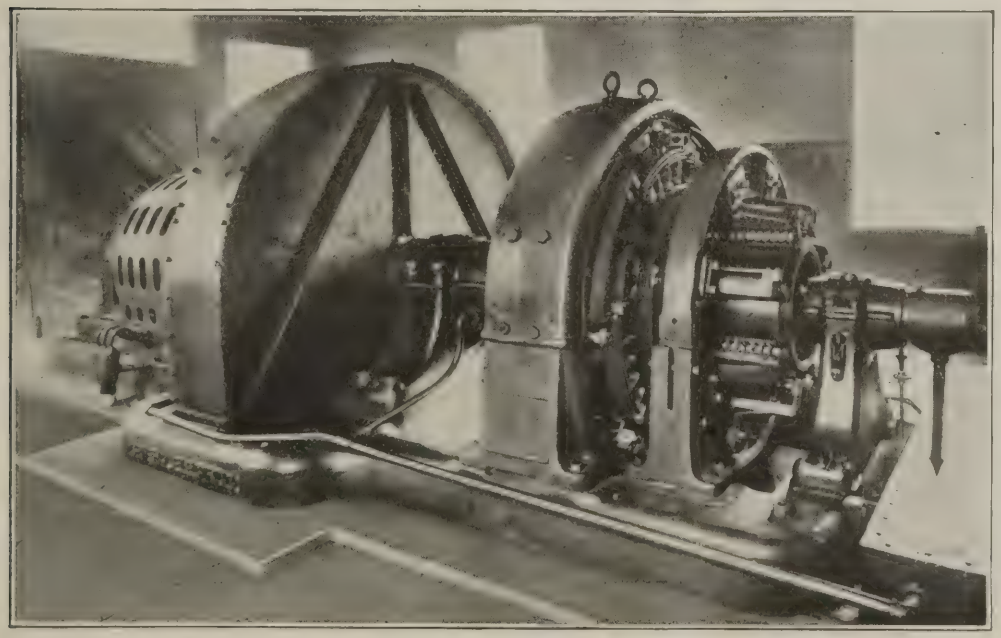

FIG 3. MOTOR GENERATOR SET FROM DIRECT CURRENT END

Outside the hoist house there are installed three 250-kv.-a., single-phase, 60-cycle, oil-insulated, self-cooled, outdoor-type transformers, which reduce the line potential from 23,000 to 2300 volts, at which voltage the power is delivered to the alternating-current motor of the flywheel set.

The speed and direction of rotation of the motor driving the hoist are controlled by varying the strength and

polarity of the generator field by means of a controller mechanically operated from a lever under the control of the hoist operator. This lever is moved forward or backward from a central or neutral position, depending upon the direction in which the operator desires the hoist to run. This actuates the controller, which is arranged to reverse the field connections and thereby the polarity of the direct-current generator. This reversal of the generator polarity also reverses the direction of rotation of the hoist motor.

A variable resistance in the field of the direct-current generator is also actuated from the controller, so that continued movement of the operating lever in either direction from the central or neutral position reduces this resistance by steps. This increases the field strength of the direct-current generator and its voltage and consequently the speed of the hoist motor.

The speed of the induction motor connected to and driving the direct-current generator and the flywheel is automatically varied in such a manner that the flywheel is caused to give up or to absorb energy as the occasion demands, and it is of such capacity that practically constant input will be taken from the transmission line when the hoist motor is operating in accordance with the required duty cycle.

The automatic variation in the speed of the induction motor is accomplished through varying its slip, by means of a water rheostat inserted in the rotor circuit of the induction motor, the resistance being altered by raising or lowering the electrodes. This is accomplished by a small induction motor (called the torque motor), which is arranged with its stator winding in series with the main incoming alternating-current supply circuit to the induction motor of the flywheel set. To the shaft of the torque motor there is rigidly attached a long arm from one end of which the movable electrodes of the water rheostat are suspended, while

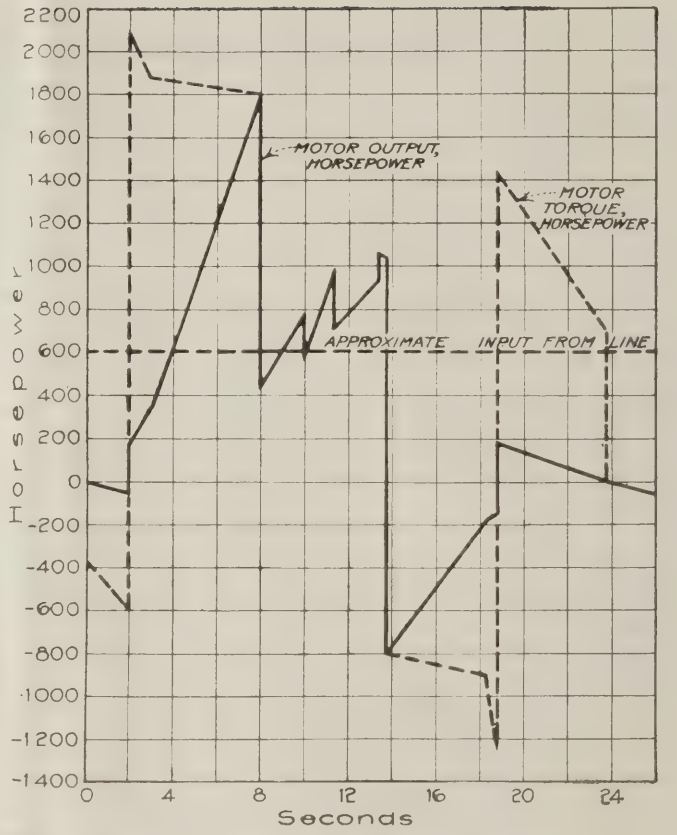

FIG. 4. DUTY CYCLE OF THE HOIST

at the other end weights are attached, thus permitting the adjustment of the balance of the moving parts.

The torque of the motor at the predetermined line current value and the weight of the moving parts are balanced against each other. When the current input to the alternating-current motor tends to increase above the constant value for which the equipment is adjusted,

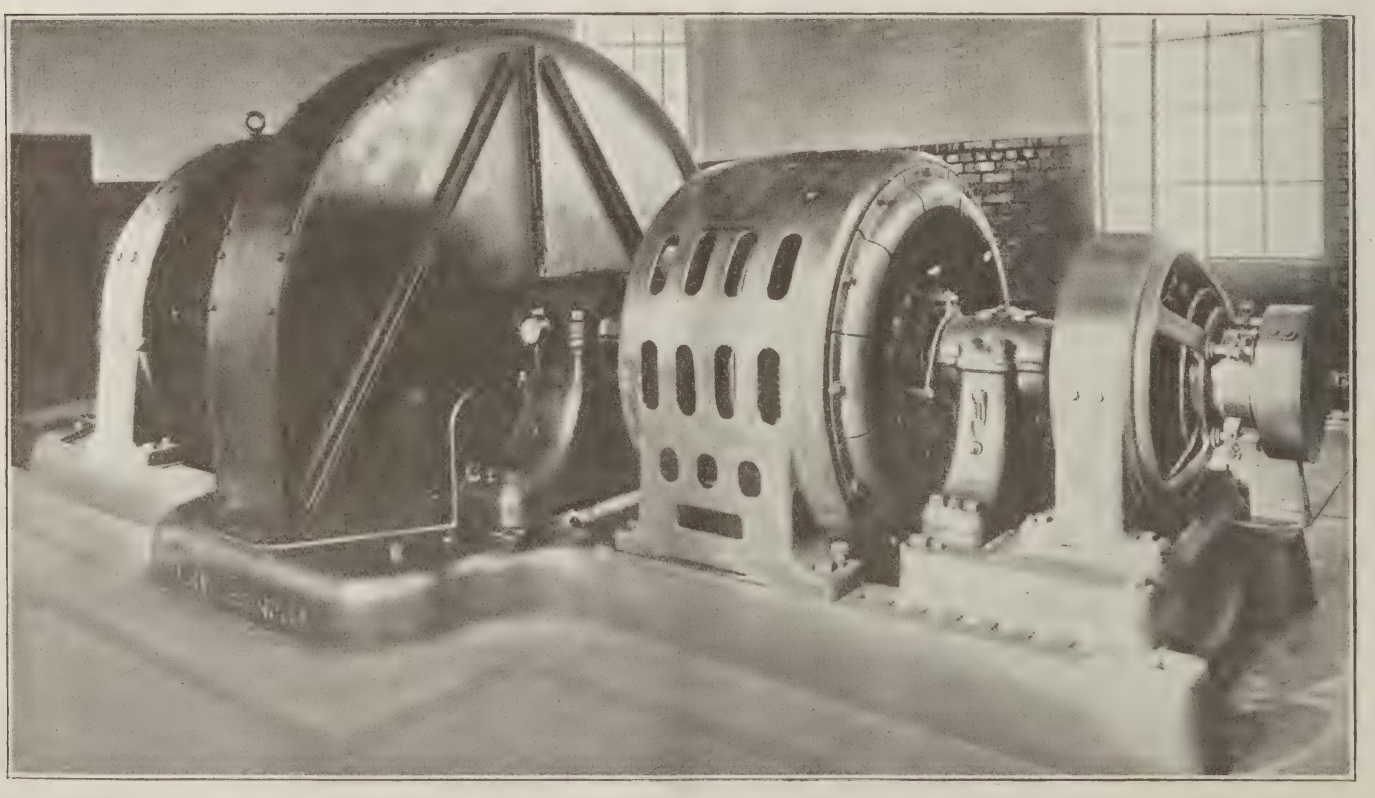

FIG. 5. THE MOTOR GENERATOR SET FROM THE ALTERNATING-CURRENT END

the added torque of the slip motor, caused by this increased current passing through its stator windings, overcomes the weight of the movable parts, raises the electrodes and thereby increases the resistance of the water rheostat in the rotor circuit of the alternating-current flywheel motor, and consequently its slip—or tends to slow it down. Thus the energy stored in the massive flywheel is given out to supply the extra demand of the hoist motor. Inversely, when the alternating-current input to the motor of the flywheel set tends to fall below the constant value, the torque of the slip regulator motor decreases, the weight of the moving parts lowers the electrodes of the water rheostat. This decreases the resistance in the circuit of the rotor of the induction motor, the set is speeded up, and the excess energy taken from the line (over that required at this time by the hoist motor) is stored up in the flywheel.

This equipment is so designed that in case of a failure of the alternating-current power supply to the motor of the flywheel set, after a trip had been started, there is sufficient energy stored up in the flywheel to completely finish the hoisting cycle and land the loaded trip at the top. Under normal operating conditions the flywheel merely gives up the necessary amount of energy required by the hoist motor during that part of the cycle in which the demand exceeds the constant amount to be drawn from the alternating-current line, having stored this up during that part of the cycle when the hoist motor demand was less than the constant amount of power to be drawn from this line. The flywheel has a normal rim speed of 3.74 miles per minute, and in dropping its speed 10 per cent. below normal will give out approximately 7000 horsepower-seconds.

For a shaft of the depth given, there is a great advantage in using a drum of the cylindro-conical form, because in this type, when properly designed, the load is accelerated and brought up to full speed on the small cylindrical part. The starting peaks are thus greatly reduced and a considerable saving in power consumed also is effected. Furthermore, there is a decided increase in the overall efficiency.

These gains, attributable to the cylindro-conical drum, are usually more marked in cases of comparatively short lifts and high rope speeds. Of course, in some cases where the starting peaks are the dominant feature in determining the size of the hoist motor required, through a reduction in these starting peaks, the size of the hoist motor is correspondingly reduced.

The use of the Ward Leonard system of control with Ilgner flywheel load equalization results, in the case under discussion, in a great saving in actual power consumed from the alternating-current line; also the peaks of the hoisting cycle are smoothed out, thus relieving the central generating station of the sudden and widely fluctuating demands that the hoist motor would otherwise make on it. All losses in gear reductions and most of those occurring in rheostats are obviated; but against these is balanced the normal flywheel rotation and other losses in the motor-generator set. However, it is estimated that by adopting the foregoing system of control and load equalization as against the regular alternating-current motor driving the hoist through a gear reduction, the actual saving in power for each trip is from 80 to 100 per cent. and the peak demand from the line of approximately 2600 hp., which would be expected with the alternating-current, geared hoist motor, has been converted into a practically constant demand of about 600 hp., or less than 24 per cent. of the peak that would occur with the alternating-current geared motor.

Of course, the comparative merits of the Ilgner-Ward

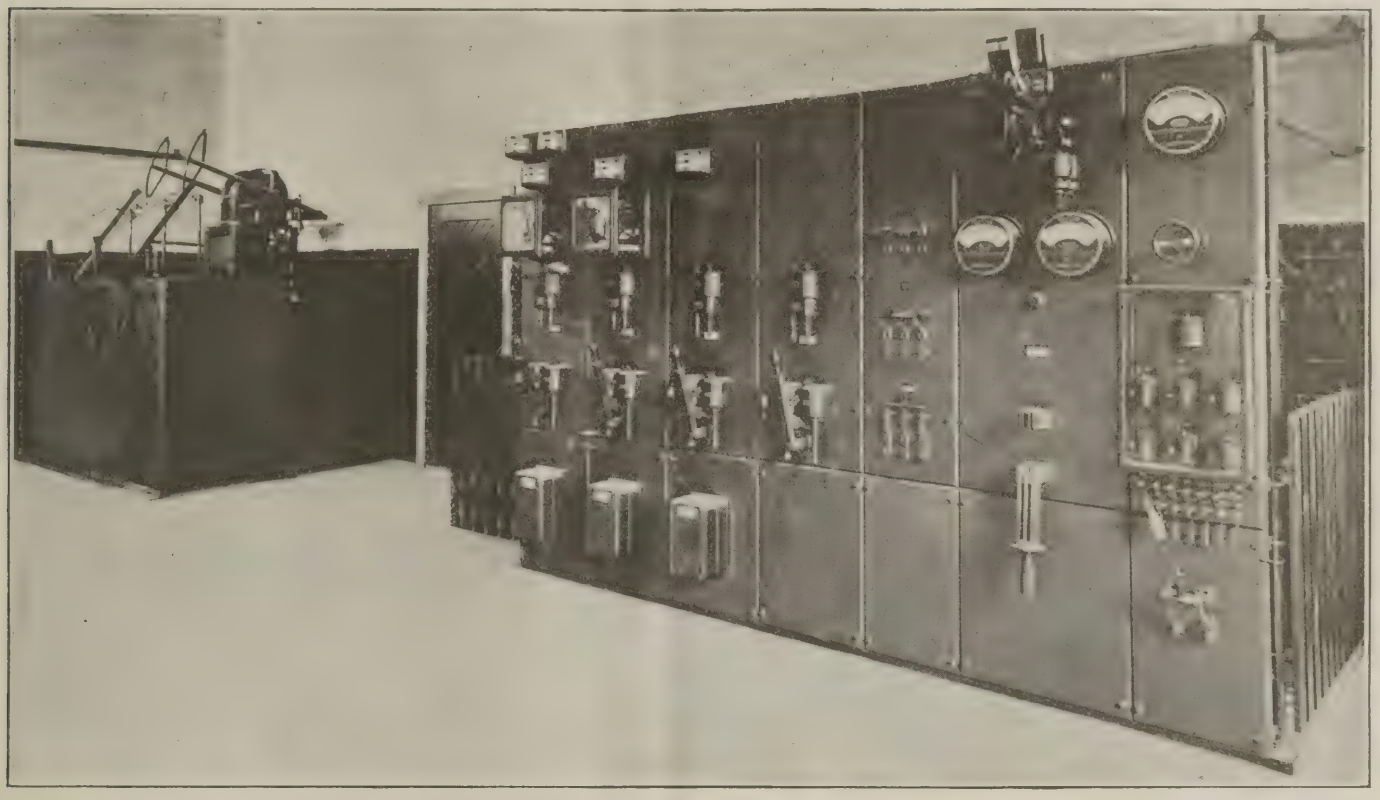

FIG. 6. THE SWITCHBOARD, SHOWING CONTROL DEVICES THEREON

Leonard system and the alternating-current geared motor should be determined for each case, because the former system will not show such marked advantages in every instance. There are cases where the power consumed might be more than that of an alternating-current geared motor, but there is in its favor in every case the practically constant demand from the line. In purchasing power where the price is based on a maximum-demand or peak-load charge in addition to the usual charge for the actual energy consumed, also even when generating one's own power, if the capacity of the generating station is not large compared to the load carried this point of constant and even demand is of great importance.

Generally speaking, the most marked advantages may be expected from the Ilgner-Ward Leonard system where the lift is moderate, the load comparatively heavy and the rope speed high. As the control equipment has to handle only the comparatively small field current of the direct-current generator, the parts are small. When in motion the hoist motor has its fields excited with but little resistance in circuit, but in order to reduce the losses when the motor is standing still the control is designed so that at this period an additional resistance (called an "economy resistance") is inserted in circuit, where the controller is brought to the neutral position. This reduces the standby field losses in the motor and also the field heating,

Comprehensive protection is secured through the use of devices which accomplish the following:

1. Automatic devices are provided which prevent retardation being accomplished in less than a predetermined rope travel. This limits the load which can be placed on the hoist motor and also the generator of the flywheel motor-generator set during this period. However, the operator is free to retard at a slower rate than fixed by the automatic devices and to run at intermediate speeds.

2. The hoist is automatically retarded at the proper rate, independent of the operator, when either cage approaches the dump.

3. In case the operator allows either cage to go past the landing by a predetermined amount, the power will be automatically cut off entirely from the hoist motor, and a relay will be operated which automatically applies the emergency brakes. This automatic device will, however, allow the operator to start the hoist in either direction from any point in the cage travel.

4. Additional overwind protection is provided by separate switches, actuated by the cages themselves, which may be placed so they will cut off power from the hoist motors and automatically apply the emergency brakes at any desired point of travel beyond the landing.

5. In case the exciter voltage or the motor field current fails, the direct-current circuit breaker will be automatically opened, thus cutting off power from the hoist motor and automatically applying the emergency brakes.

6. A hand-operated emergency switch is provided within easy reach of the hoist operator, by means of which he can automatically cut off power from the hoist motor and apply the emergency brakes.

7. When hoisting men limit switches are provided, which prevent the operator from allowing the cage to go past the main landing.

8. Additional generator field resistance is provided and so arranged that when hoisting men the hoisting speed is further limited.

9. The special safety devices employed when hoisting men have their control circuits so interconnected with a signal system that a visible signal is given to the men to be hoisted, showing that such safety devices have been put into operation.

Coal Mining in British Columbia

By R. DUNN
Victoria, B. C.

SYNOPSIS—*British Columbia, as well as other portions of the Canadian Northwest, is anticipating a coal famine next winter. The demand for and output of coal is now stronger than ever before. Men are scarce, the cost of supplies high and still rising, equipment is difficult to secure, and new development is thus strongly retarded.*

THE vital importance of coal to the industrial and domestic life of the country is being brought home more forcefully every day to the people of Canada. In British Columbia, a coal-mining center, this is specially noticeable because in the past, with producing mines a few miles away, coal had come to be taken somewhat as a matter of course; something which, everybody agreed, cost far too much but which could, at any time, be secured in any quantity provided the price was forthcoming.

Circumstances are changing. The collieries are working at a high pitch. They are turning out as much coal as the men and equipment available can produce. New mines are being opened, and yet the prospects are that the demands on British Columbia coal this year will far exceed the supply. It may well be asked: "Why is this so? In what way have conditions so materially changed in the last few months as to warrant the assertion that this province, at present producing coal at a greater rate than for many years, despite the handicaps of labor shortage and high prices of mine equipment, is unlikely to be able to fill all orders?"

In answering these questions the position, not only in British Columbia, but throughout the Pacific Coast states and the Western Canadian provinces, has to be considered. First let us glance at the records with respect to the sale of coal by British Columbia in the years 1916 and 1917. These are as follows:

SALES IN 1916

Coal:	Tons
Home consumption	858,052
Export to United States	837,879
Export to other countries	6,166
Total	1,702,097
Coke:	**Tons**
Home consumption	233,456
Export to United States	34,377
Total	267,833

SALES IN 1917

Coal:	Tons
Home consumption	935,469
Export to United States	754,568
Export to other countries	38,211
Total	1,728,248
Coke:	**Tons**
Home consumption	147,811
Export to United States	12,711
Total	165,022

It is important, in order to properly grasp the story told by the foregoing figures that it should be understood that "home consumption" means, in the strictest sense, just what the words convey provincially; that is to say, none of the coal so classified goes outside the province. Therefore, it will be seen that almost half of British Columbia's production has gone and continues to go to the adjacent states—the greater part to California. To the coal miners and operators this is an important market, developed to its present state in the course of 50 years of trade.

It is not saying too much for the coal of Vancouver Island, from which section the coal for export chiefly comes, that the consumers of the State of California would not relish the idea of being forced to make a change. It follows that everything possible will be done, as far as the operators are concerned, to maintain their obligations both in respect of home consumption, which is a first consideration and has been always so considered, and in regard to the needs of the people of the southern Pacific state.

But on top of these considerations come two new developments. One is the demand that the coal fields of British Columbia and Alberta[1] supply, if not fully, to a much larger extent than heretofore, the requirements of the Canadian prairie sections as far east as the Great Lakes. This includes the large market of the Province of Manitoba which, in the past, has depended on the anthracite of the States. Another is the possibility of the local British Columbia market being indefinitely expanded through the cutting off by the United States Government, as a war measure, of the fuel-oil supply to the Northwest from California.

In regard to the former its seriousness to the prairie provinces and the necessity for concerted action of some sort were the subject of addresses by C. A. McGrath, fuel controller for the Dominion of Canada, and C. W. Peterson, deputy fuel controller, at a public meeting held in Winnipeg on the evening of Tuesday, May 14. On or about that date Mr. Peterson gave a statement to the daily press as follows:

> In regard to the coal situation as it affects the prairie provinces, I may say that the only positive statement we have from the United States authorities at the present time is that anthracite shipments to Western Canada will be materially restricted. As a matter of fact we have no positive assurance that any anthracite at all will be shipped to the head of the lakes. It should not be forgotten that the coal situation changes almost from day to day in sympathy with the variations of output and the demands from every source. As an illustration I may mention that events have transpired recently that will probably render it necessary for the continent of America to find additional coal supplies for one of the Allies. This may easily prove an important factor in the coal situation during the coming winter.

A few days later Mr. Peterson held a conference

[1]What is said herein applies, generally speaking, with equal force to Alberta and Saskatchewan, although references to local conditions mean conditions in the Province of British Columbia. That the operators of Alberta are doing their utmost to meet the situation is shown by the remarkable jump in their output for the year 1916, although the figures available indicate that difficulties, which may be classified as national and provincial, brought down the production of the year 1917. The totals, as far as available here, are: Alberta, 1915—3,434,891 tons; 1916—4,648,604 tons; and for the first three quarters of the year 1917—2,213,501 tons. In Saskatchewan the output for 1915 was 237,249 tons and for 1916, 267,234 tons.

with the coal operators at Calgary, Alberta, the object being to discuss and decide upon measures for the speeding up of production.

It is not necessary to devote more than a few words to the other development referred to, namely, the necessity of replacing fuel oil with coal should the California oil be withdrawn from the Northwest, because this, although predicted, has not yet transpired. If it does, however, the result will be a further draft on the coal supply of the province of considerable proportions, as the liquid fuel is used largely by the Esquimalt & Nanaimo Ry., the only important railway of Vancouver Island, and by all passenger train locomotives operating on the mainland of British Columbia. It is true, in connection with the latter, that coal gradually is replacing oil, but the sudden cessation of importations will unquestionably materially strengthen the home coal market not only in respect to the transportation companies, rail and water, but with regard to industrial plants, business blocks, etc.

As a further illustration of what this means to the province it may be said that conservative estimates place the quantity of oil used in British Columbia at approximately 8,000,000 barrels per year, or the equivalent of about 2,500,000 tons of coal.

And now the other phase of the situation may be given brief scrutiny. What is the condition in the province and how are the operators of the collieries that are expected to meet this increased demand placed? Generally speaking, the condition cannot be said to be a happy one. Operators have problems of a character that have never in the past been faced. To begin with, there is the labor question. While in some districts there is no appreciable lack of men to handle the present output of the mines of these particular localities, in other sections, where the mines possibly are not as modernly equipped and the conditions under which the workers are toiling are perhaps more onerous, there is a distinct and unfortunate shortage.

Wages Have Gone Up Considerably

It goes almost without saying that wages have increased to a large extent, but the mine managers have met the demands in this respect in almost every instance, and it is gratifying to be able to report that the relations between employee and employer are amicable and satisfactory. The operators have recognized that the general increase in the cost of living entitles the men to more wages, while the fuel controller, of whom more anon, when appealed to by the employers has consented to an increase in the selling price of coal. Thus the burden, as is always the case, has been shifted to the broad but, in recent years, somewhat staggered shoulders of the body politic.

But the point that I want to bring out here is that, with this position as to men, the collieries are at a decided disadvantage in their efforts to further develop the coal fields by the opening of mines and thus increase their production. It is to their credit, therefore, that despite difficulty they are going ahead, crossing no bridges before they are reached, and so far under the circumstances they have been able to accomplish wonders.

It will be interesting here, perhaps, to review a little history—not ancient history, for the events in question happened only last year and have a bearing on future prospects. In the fall of 1917 there developed considerable agitation among the municipal officials of the cities of Vancouver and Victoria, it being the contention that the coal dealers were charging outrageous prices. About that time the fuel controller for the Dominion appointed a British Columbia representative in the person of Nichol Thompson, a citizen of high standing and a business man with long experience in connection with eastern Canadian collieries. Through Mr. Thompson and the Hon. William Sloan, minister of mines, an investigation was instituted into the cost of the production of coal and of the handling charges from the mine to the consumer. As a result it was made fairly clear that the profits of the middleman were not exorbitant, certainly not as exorbitant as newspaper articles, based on ex parte statements, had indicated.

Would Not Buy Coal in Summer

It served the purpose, however, of bringing out the fact that residents of these municipalities, and of New Westminster, B. C., as well as other parts of the province, were in the habit of postponing their coal purchases until the winter and that through the summer the collieries often found no market for their output. The result was that orders were crowded into six months, demand exceeded production, and coal famine threatened. Fortunately the winter of 1917-18 in the Pacific Northwest was unusually mild and the condition feared did not develop.

However, it is hardly to be expected that the same conditions will prevail in the winter of 1918-19. Profiting by the experience of the past, and realizing the imperative need of being in a position in the months to come, to supply, not only British Columbia, but the established market of California and the prospective market of the Canadian prairie provinces, the colliery managers and the dealers of this province are inaugurating a campaign with a view to having local residents lay in their winter's supplies this summer, thus assisting in the even distribution of the demand.

To this end, and with the object of establishing the machinery through which the people may be impressed with the need of conserving coal and of the various methods of doing so, the Dominion Government recently passed an order-in-council authorizing the provinces to appoint fuel administrators within their several jurisdictions and giving each municipality power to appoint a fuel commissioner. It is felt that this will have the effect of bringing into operation an immense organization throughout Canada by means of which an effective educational campaign may be waged.

One of the pleasant features of the present position in the Northwest is the good feeling between the men and the managers, to which I have referred. This has been brought about by a disposition on both sides to recognize each other's difficulties and to make concessions. An instance of this was brought to my attention the other day. The employees of a certain Island company wanted an increase in pay. They took the position that the rise in the cost of living had so diminished the value of the dollar that more money was essential. A committee was appointed to wait on

the management, by whom it was received courteously and its representations listened to sympathetically.

The case for the men had been thoroughly prepared. Statistics were submitted showing the augmented cost of various articles of food and clothing and proving, beyond a question, that what might have been considered a fair scale some months ago was not so now. The management replied, in effect: "We recognize the force of your argument, but we cannot, without losing money, pay you more. To demonstrate our good faith you are welcome to review our books. They are open to any auditor in whom you have confidence, and the examination can start now if you so desire."

The men accepted this invitation and the report substantiated the company's position. "Very well," said the men, "we recognize that your shareholders are entitled to a reasonable return on their investment. We still think we are justly entitled to a living wage. Therefore we will gladly join you in demanding of the fuel controller authority to increase the selling price of coal at the mine." This course was adopted, with the desired effect, and peace and good feeling was maintained.

Shortly after the war began the miners of Vancouver Island, and this applies in general to those of all British Columbia, were given a 5 per cent. war bonus which was followed by a 5 per cent. time bonus, its purpose being to encourage continuous work. On Jan. 1, 1917, there was a 10 per cent. straight bonus, and in December of the same year another bonus of the same magnitude and character. On Apr. 15, 1918, the latest increase was agreed upon, namely, 50c. a day straight bonus. In other words, the wages of the miner in British Columbia have risen 30 per cent., together with a straight 50c. per diem, since the outbreak of the war. When this is taken into account in conjunction with the fact that supplies have soared, broadly speaking, 80 per cent. (some of the high-grade steel material having climbed as much as 160 per cent. over the prewar prices), some conception of the problems with which the operators are dealing may be obtained.

Circumstances would not be so difficult if the prices of coal had risen in the same ratio or if, even at the prices quoted, equipment was readily obtainable. As to the former, in January, 1917, there was an increase of 10c. a ton; in July of the same year another of 65c. a ton; and in February, 1918, another of 30c. a ton. With respect to the latter, the demands being made upon all the large industrial plants of the United States and Great Britain, the restrictions imposed on exportations, and the transportation difficulties have made the obtaining and delivery of equipment so uncertain and the delays so extended even when all arrangements have been perfected, as to seriously hamper the new development of coal fields.

The selling price of coal at the mine is now $5.80 per gross ton as compared with $4.25 and $4.50 in 1914. This will give some idea of the enormous advance in costs throughout the Northwest. It almost goes without saying that, in the face of these figures, a further increase in the selling price of coal by the dealers will be necessary.

Whether British Columbia will be able to accomplish everything that seems to be expected of her in meeting the demands of the home, the prairie and the southern markets remains to be seen. It must be apparent that the coal-mine managements have a stony path to tread but, if they fall short, it will not be their fault as far as can be judged at the time of writing. The miners, too, are coöperating. But lack of mechanical facilities and shortage of labor in some districts are difficult hindrances to overcome, and it will be imperative, if serious emergencies are to be avoided during the winter of 1918-19, that the public be fully apprised of the facts and instructed as to how it can best buy and save in order that, while having sufficient fuel for ordinary needs, the heavy demands may be so evenly distributed as to enable the producers to deal with the extraordinary situation which the exigencies of the war have developed.

Views of Anthracite Stripping

The accompanying illustrations show two views of the Delaware & Hudson strippings at the Plymouth No. 4 Colliery in the Borough of Larksville, near Kingston, Penn. The photograph on the left shows the Cooper and Bennett coal beds at the point where the entry is made to the underground workings. The photograph on the right shows a shovel making the second cut in the removal of overburden. The Larksville Mountains are seen in the distance.

DELAWARE & HUDSON STRIPPINGS AT THE PLYMOUTH NO. 4 COLLIERY NEAR KINGSTON, PENNSYLVANIA

The Snow-Bird Mine

By S. C. REYNOLDS
Houston, Penn.

SYNOPSIS—*The total number of wagon mines in operation in this country is somewhat over 2000. Although the operation of such mines has been criticized, frowned upon and discouraged in every way, they often reclaim coal considered as worthless by the big producers. During the past two years they have placed upon the open market several million tons of coal at a time when it was sorely needed.*

DURING the last two years a good deal has been said of, and more or less interest taken in, the small mines eligible to the "snow-bird" classification. While at first thought it would seem that the "pesky wagon mine"—as it was referred to in an editorial comment in *Coal Age* some months ago—could hardly warrant much interest, yet, when it is realized that during the past two years considerably over 2000 wagon mines have been opened up in the coal fields of this country, it will readily be seen that this is a matter of some importance to those in charge of the fuel problem of the nation. This problem is now more vexing than ever before.

Many reasons have been advanced—principally, however, by those who were hardly in a position to speak in an impartial manner—as to why the "wagon mine should be weeded out." It has been charged that the small mine is wasteful of labor; that the miners could be used to better advantage in the larger and better equipped mines; that these operations are wasteful of the teamster's time who hauls the coal from them, and that railroad cars are kept idle which otherwise might be in use. After all, I wonder if the last reason given why the "pesky wagon mine" should be weeded out isn't really the only reason that would stand a fair analysis. While any business that in any way hampers the already overtaxed railroad equipment should be eliminated, if possible, it is also true that any harm done in this respect by the small mines has been counteracted a hundredfold by the thousands of tons of coal produced by them and thrown into the open market at a time when it was sorely needed.

Aside from being personally interested in a mine of this sort—which I confess at the start—I have had an unusual opportunity to watch the development and the work carried on by at least 200 mines of this class in Pennsylvania alone during the past two years; and while my business with them pertains only to workmen's compensation, I have naturally absorbed a good deal of first-hand information about these small mines which are scattered throughout the coal fields.

THE DUMP OF A SNOW-BIRD MINE

One of the principal assertions advanced by those who desire the elimination of the wagon mines (that they are wasteful of labor) can readily be disproved, because, as a matter of fact, while these numerous mines as a whole have produced several millions of tons of coal during the last two years, the labor used could probably not have been employed to better advantage. I have invariably found that the majority of miners digging coal in these small mines are men who for various reasons do not care to work in the bigger railroad operations.

The miners who as a rule dig coal in these small developments are frequently local characters who prefer

MOTOR TRUCK RECEIVING ITS LOAD

to work only in such mines, where they can be, in most instances, within a few hundred feet of daylight, unhampered by union regulations, or the necessity of waiting on the "machine man" to cut their place; where they can go to work early or late as the humor strikes them, and "knock off" when they choose. I know of dozens of instances where their tonnage loaded over a period of a month compares favorably with that of the miner in the big mine. The fact that there is seldom a strike or a general lay-off on account of a "hunky" wedding or christening helps to equalize any difference in efficiency in favor of the miner in the larger mine by reason of machine mining.

Hundreds of these small mines that are operating today in spite of what seem unjust conditions are supplying coal to the consumer direct from the mine, also to local industries by wagon and automobile trucks, which otherwise would have to draw upon the railroad mines for their supply. Furthermore, I happen to know that a great many industrial plants that are

GENERAL VIEW OF SNOW-BIRD TIPPLE

now getting their coal supply in railroad cars from the larger mines could have secured their fuel requirements direct from small operations adjacent to the plants had provision been made by our Fuel Administration to allow the small mine operator to charge a price for his coal that would make it possible for him to operate.

A year ago scores of these small mines were hauling coal in wagons and trucks over distances up to four or five miles. I have in mind now two different snow-bird mines that were opened up near Pittsburgh with conditions much alike. The coal was the thin vein. About $15,000 was invested in automobile trucks and the necessary equipment. Coal was loaded in cars at a railroad siding two miles distant. It was loaded principally into cars that had been emptied of their freight and were not moved until loaded with coal. Everything went beautifully as long as the price of coal was above the $3 mark, but anything below that figure defined the difference between a working profit and a loss. Consequently, after Government restriction they shut up shop and the tonnage available from the two was lost from the market.

The small mine operator has been hampered and discouraged at every turn. For many weeks the railroad companies refused him cars in which to ship coal. Later it was decided to permit him to load only box-cars and allow 75c. per ton above Government price, which with present labor conditions about pays for shoveling the coal from the wagon or truck into the car, to say nothing of the cost of the haulage from mine to railroad siding. And the 75c. allowed above the mine price for loading box-cars is the price regardless of whether the distance from the mine to the loading point is 500 ft. or five miles.

Acres of crop coal that otherwise would have been left in the hillsides have been mined during the last two years by the wagon miner, and from a conservation standpoint that fact alone is surely commendable. Within sight of where I write a couple of men leased the crop line from the owner of a farm from which a big operator had taken all the coal he thought worth while and drew the stumps and abandoned the property as being worked out. Since the first of June, 1917, however, that crop line has produced over 20,000 tons of coal. And the lessees are still producing.

The wagon-mine operator has come in for a good deal of criticism from the big mine operator whenever the opportunity arose. This is natural. There is the same reason for affection on the part of the big mine operator for the wagon-mine operator as there is for evidence of a warm feeling by the street car company for the "jitney bus," or the big department store for the small corner grocer.

However, as remarked by an editor of national repute a few days ago, "If you know of any way to increase the fuel supply of the country at this time, it is your clear duty." But, making conditions such that it is impossible for the small mine operator to produce coal, or discouraging the mining of coal in any way, regardless of the size of the operation, is not, in my opinion, the best thing to do.

The New Harewood Mine

Harewood mine is one of many recently opened on Vancouver Island. It is situated about four miles southwest of Nanaimo, which is the central city of this famous coal field.

This mine is owned and operated by the Western Fuel Co., of Nanaimo, with offices in San Francisco. This company was recently reorganized. G. W. Bowers has been appointed general manager, and John Hunt, superintendent, was promoted to general superintendent. The search for new mines has gone steadily forward.

The Old Harewood mine was visited and explored and there was found enough coal in the old pillars to warrant reopening the mine. This is the third time this mine has been opened. It was first opened about 40 years ago, when the coal near the outcrop was worked for a short period.

In 1902 the mine was again reopened and was more extensively worked, a shaft being sunk on the east side of the ridge, where the seam was cut at a depth of 150 ft. and the coal worked from this point to the raise joining with the former workings through two levels. The operation was closed down again in 1904 and reopened in August of last year.

Since that time the old mine has been developed fairly rapidly and is now producing 750 to 800 tons of coal daily with about 200 underground employees. It is now the second largest producer on the island, the No. 1 shaft at Nanaimo holding premier place.

The power for the working of the mine is electric and is supplied from generators situated at the old shaft, which is now used as the upcast. A Murphy fan supplies about 30,000 cu.ft. of air per minute to the mine and runs at half capacity. The haulage is performed by two Jeffrey locomotives in the main levels, while electric winches are used in hauling coal up the dips.

The coal varies greatly in height, increasing in places to 20 ft. in thickness, while the greater portion of the bed will average between 4 and 5 ft. Numerous rolls and faults are found on the dip side of the main level, while to the raise the coal thins down to about 2 feet.

The Western Fuel Co. has accomplished much in the operation of this mine which helps considerably to maintain this firm's daily output of nearly 3000 tons derived from three mines. Hopes are entertained of a still further increase which will augment the production to the coveted 1,000,000 tons for the year's operations.

Recovery of Byproducts in Coke Manufacture

By M. MEREDITH
Liverpool, England

SYNOPSIS — *The employment of byproduct ovens in preference to those of the beehive type has greatly increased in Britain in recent years. The present war has stimulated byproduct coking largely on account of the demand for high explosives made from certain of the byproducts. Future practice will doubtless demand the mixing of coals before carbonization is begun.*

THE erection of modern coke ovens with the necessary appliances for the saving of the byproducts in coal, and the extraction and working up of the various products, must ultimately come into use everywhere and is a matter which requires serious consideration on the part of all coke manufacturers.

With the gradual disappearance of the old prejudices against coke made in the byproduct ovens, the modern process has now come into use and begun to assert itself. In 1898, in England, 1¼ million tons of coal were carbonized in byproduct coking ovens; in 1905, the quantity of coal so treated reached roughly 3½ millions, and in 1909, 7½ millions of tons. Evidence given before the royal commission on coal supply in England shows that the value of the byproducts will not only pay for the working of such coke plants and provide a profit, but will also pay for the capital outlay within 10 years.

In the United States modern coking and byproduct plants have been erected in many districts and are extensively operated. In Canada, in 1915, there were only two byproduct coke-oven plants, yet these two were responsible for two-thirds of the total coke production of the Dominion.

Modern byproduct recovery coke plants have recently been installed in certain places as a means of supplying city gas, but such installations are at present only possible where there is a good demand for metallurgical coke. It is not improbable that, in years to come, this matter will receive serious consideration and coke plants will be fitted with modern appliances for the saving of the byproducts. With the rapid depletion of coal supplies this will be rendered highly necessary.

The wasteful loss of valuable material by the beehive process of carbonizing coal must sooner or later be considered, and the modern process introduced in the manufacture of coke, the whole question being a national and economic one. There has been a decided prejudice against the use of retort-oven coke, the fuel from the beehive ovens being more in demand for use in blast furnaces. This preference is now disappearing, and it is generally recognized that retort ovens make as good a coke as beehive ovens, and give a high yield in coke when operated on ordinary coking coals. Beehive ovens are stated to burn about 10 per cent. of the coal itself —that is, if a coal will yield 75 per cent. of coke in a retort oven, probably only 65 per cent. would be obtained from a beehive oven.

Germany owes largely to her modern methods of treatment of coal and coke the large amount of high explosives she has been able to use against the Allies in this war. The byproduct coking plants which are favored in England are the Otto-Helgenstock, Simon-Carves, Koppers, Somet-Solvay, Simplex, Coppée and Hussener. According to A. W. Belden (United States Bureau of Mines): "The yield of byproducts is dependent on the working of the ovens and can be regulated within certain limits at the option of the operator. The manipulation of the ovens depends in large degree upon which product is more desired. Ideal conditions are reached when a coke possessing the chemical and physical properties necessary for the purpose for which it is intended is produced, together with a maximum yield and quality of byproducts."

True Distillate from Byproduct Oven

In a byproduct oven a true distillate of coal is obtained, the process being under control so that it can be regulated. From the ovens the volatile matter passes through the uptake pipes and is driven along the ovens by means of exhausters. En route to the exhausters it passes along a hydraulic main laid along the top of the ovens to a chamber where it deposits tar and a small portion of ammonia. The gas having deposited the greater part of its tar is then passed through air coolers, water coolers, scrubbers, exhausters, tar extractors and ammonia washers, to a gas holder. After the gas has been deprived of its tar and ammonia it is then treated by certain heavy creosote oils, which absorb from it the benzol contained therein, and benzols of various degrees of strength are manufactured therefrom. The following is a typical analysis of the gas produced:

	Per Cent.
Hydrogen	50.0
Saturated hydrocarbons	34.0
Unsaturated hydrocarbons	4.0
Carbon monoxide	8.0
Carbon dioxide	2.0
Oxygen	..
Nitrogen	2.0
	100.0

Inflammable constituents of this gas amount to 96 per cent.

To the ammoniacal liquor from the ammonia washers lime is added, and the mixture then distilled, the ammonia (NH_3) being passed into sulphuric acid to form ammonium sulphate; or it is pumped into a condenser and saturated to form stronger liquor, varying in NH_3 contents, but usually containing between 15 and 20 per cent. The quantity obtained depends on the nitrogen content of the coal, but other factors, such as the shape of the retort ovens, temperature, etc., have an influence on the fraction of nitrogen which is given off as ammonia.

Nitrogen may be present in coals to the extent of 1 to 2 per cent., but in gas works probably only about

14 per cent. of this is saved as ammonia in the gas, although the percentage may be increased by the addition of lime to the coal, or by passing steam through the retort during distillation. In the dry distillation of coal about 2 per cent. of the nitrogen of the coal is evolved in the form of cyanide and recovered.

NH_3 yields per ton carbonized at gas works from different coals:

	Lb.
Pelaw Main, Maitland	91
Newcastle	7½
Western district	4
Southern district	2½

The ammoniacal liquor, after concentration, is bought on the NH_3 content basis by the manufacturers of ammonia, by whom it is largely made into anhydrous ammonia (used for refrigerating purposes), or into sulphate of ammonia.

Tar and Other Products

The composition of the tars varies with the apparatus employed, method of working and class of coal coked. The following is a typical analysis of gas works tar:

On Distillation Yields	Per Cent.
Water	2.20
Light oil	5.90
Middle oil	12.30
Heavy oil	12.00
Anthracite oil	16.00
Pitch	49.70

Specific gravity, about 1.10.

The following amounts are stated to be obtained from the distillation of tar at ordinary gas works:

From One Ton of Tar Distilled:		
Ammoniacal liquor	3	gal.
Crude naphtha	10	gal.
Light oils	4	gal.
Carbolic acid	1	gal.
Creosote	56	gal.
Anthracine cake	3	lb.
Pitch	13	cwt.

The light oils, which are from 3 to 6 per cent. of the original tar, contain:

	Per Cent.
Phenols	5.0
Pyridines	1.0
Sulphur compounds	0.1
Neutral substances	1.0
Hydrocarbons	80.0

The middle oil, which constitutes 8 to 12 per cent. of the tar, contains:

	Per Cent.
Phenols	10.0
Cresols	20.0
Naphthalene	30.0
Residue, heavy oil	4.0

In addition, the oil contains considerable amounts of pyridine and other bases. The heavy oil, 10 to 12 per cent. of the tar, a semi-liquid product, contains:

	Per Cent.
Naphthalene	30.0
Cresols and homologues	10.0
Pyridine bases	6.0
Hydrocarbons (?)	40.0

Crude naphtha is usually worked up into a standard strength, which yields 20 per cent. of benzol when distilled up to a temperature of 120 deg. C. This is sold to the dye makers, who break it up into benzol, toluol, solvent naphtha, burning naphtha and creosote. The dyes are made from benzol and toluol. Solvent naphtha is used by mackintosh makers and others for dissolving india rubber; burning naphtha is employed for consumption in lamps, etc.; creosote for the preservation of timber, etc.

About a 20 per cent. quality of light oil distills over at 160 deg. C. This is sold to the refiners, who convert it into toluol, solvent and burning naphtha and creosote, for all of which products there is a growing demand.

Carbolic acid is made by washing the crude naphtha and light oils with a 10 per cent. caustic soda solution. The aqueous alkaline liquid is drawn off from the oil, and steam blown through, in order to volatilize any trace of the naphthalene or other hydrocarbon that it still contains. The alkaline liquid is then neutralized by sulphuric or carbonic acid, and the precipitated oily layer or phenol drawn off and fractionally distilled in stills provided with zinc or silver condensing coils. The distillate is crystallized out by cold and separated from the still fluid cresols by a centrifugal machine. Phenol is thus obtained, almost chemically pure, as a white solid. It is used principally for making picric and salicylic acids. The cresols separated from the phenol occur as a fluid mixture of these isomers. They are much used for disinfecting purposes.

Pitch readily commands a sale for asphalting and for many other purposes. Large quantities of pitch were formerly shipped to the collieries of Belgium and the north of France and used for the manufacture of briquettes, the pitch acting as a binding material.

If cheap tar or pitch is produced in sufficient quantity as one of the byproducts in coke manufacture, it could be utilized largely for briqueting the fine dust and coal which accumulates in large quantities in a colliery which yields a coal unsuitable for coking. In certain centers there is a large amount of fine coke or breeze obtained from the coke ovens, which if briquetted would make an excellent fuel. To briquet the fine coal it is washed in the ordinary way and dried, then mixed with 7 or 8 per cent. of tar and molded into bricks by machinery.

The briquettes possess the following advantages: They are less friable, when properly made, than coal lumps, and being of regular shape they are more readily stored. For domestic use they have the advantage of not soiling the hands, and they can be purchased by count, so that a check is kept on the weight supplied. The briquetting of the fine coal dust will become an important industry, as the supplies of the better class of coals become reduced.

Many Valuable Byproducts Recovered

Trinitrophenol is used extensively for filling shells, and its salts have formed constituents of priming compositions and of powders used as propellants. The honey-yellow color of the molten acids suggested the name of "melinite," which it received in France, while in other countries it is designated as "liddite," "pertite," "ecrasite," or "schimose," in Japan. Trinitrotoluene is manufactured from pure toluene. It has sprung into prominence as a substitute for picric acid, chiefly owing to its freedom from acid properties, its low melting point and great stability. Trinitrotoluene has been introduced in the French service under the name of "tolite." The Spanish Government calls it "trilit," and it is also known as "trolyl," "trinol," etc.

The first Australian plant for the making of coke and saving of byproducts was erected in Newcastle (the Australian Coking and Byproduct Co.), but is not now working. The Broken Hill Proprietary Co.'s works, erected at Newcastle, may be said to be the successful pioneer of the byproduct industry in New South Wales. This company makes metallurgical coke, ammonia, gas, tar, etc. The tar, for treatment and extraction of the

byproducts contained therein, is taken over by De Meric, Ltd., tar distillers. This firm has works at Hamilton and has lately erected an up-to-date plant adjoining the Broken Hill Proprietary steel works. The chemist, John Paton, has supplied the following information in regard to the work taken in hand at these works.

The tar is distilled and fractionated into light, middle and heavy oils, distilling at temperatures of 100, 120 and 170 deg. C. respectively. From the light oil benzol, toluol and solvent naphtha are made. It is further treated, and pyridine, xylol, benzol and toluol obtained, the benzol and toluol being brought up to 90 per cent. strength. From the middle oil carbolic-acid crystals, neutral oil, cresylic acid and naphthalene are made; also it is proposed to manufacture disinfectants later on. The heavy oil by fractionation yields creosote, anthracene and dead oil for lubrication. The tar will be carried into pitch, and from the pitch lampblack will be made.

Coke Making and Byproducts Saving

For the making of good metallurgical coke with the byproduct ovens, and to obtain a maximum result from the byproducts, it probably will be found necessary to blend certain coals with others giving higher percentages of volatile matter. The high-class coking coals in some districts are gradually being depleted and experiments will be necessary to blend them and so obtain the maximum coke and byproducts contained in other coals. According to A. W. Belden (United States Bureau of Mines), "the best results seem to be obtained when coals are mixed in proportions that give about 25 per cent. of volatile matter in the mixture, and this practice is generally followed throughout the country where mixed coals are used."

The great waste of gas and loss of all byproducts by the use of the beehive ovens in the coking of fine coal to produce a metallurgical coke only will have to be seriously considered in the erection of future plants, and the question of costs thoroughly gone into; also the suitability of coals, separately or blended, for the making of metallurgical coke, byproduct extraction and the utilization of the gas for power, or heat generation.

Legal Department

Iowa Mine Safety Law—Under the Iowa statutes, a miner need not notify his employer that a mine roadway needs timbering in order to render the latter liable for injury resulting from negligent failure to timber. (Iowa Supreme Court, Erickson vs. Maple Block Coal Co., 167 Northwestern Reporter, 105.)

Refuge Holes in West Virginia Mines—The duty to see that refuge holes along motor roads in West Virginia coal mines are maintained, as required by the statutes of the state, rests on the mine foreman, not on the mine owner, and for injury to a miner resulting from defects therein the mine owner is not liable. (West Virginia Supreme Court of Appeals, Kinder vs. Boomer Coal and Coke Co., 95 Southeastern Reporter, 580.)

Negligent Operation of Mine Motor—Although it was not negligent for a mine motorman to back his motor a short distance without reversing the trolley, it was negligent to move the motor so carelessly as to permit the trolley to leave the wire, causing injury to a boy employed to attend the trolley, and the employer is liable for such injury. (Kentucky Court of Appeals, Borderland Coal Co. vs. Miller, 201 Southwestern Reporter, 299.)

Effect of Indiana Employers' Liability Act—Under the Indiana Employers' Liability Act, a coal operator is liable for death of an employee while assisting in undercutting a vein of coal and due to negligent failure of other employees to remove coal loosened from the vein; the injured employee being himself free from contributory negligence. (Indiana Supreme Court, J. Wooley Coal Co. vs. Tevault, 118 Northeastern Reporter, 921.)

Cancellation of Federal Coal Land Patents—Under the Federal statutes which forbid more than one entry upon public coal lands by the same person or association of persons, entries cannot lawfully be made in the interest of persons or associations who have exercised their own right of entry. Patents based on entries pursuant to a scheme to enable a person or association to obtain lands in excess of the area allowed by such statutes are fraudulent and subject to cancellation. (United States Circuit Court of Appeals, Eighth Circuit; United States vs. Kirk; 248 Federal Reporter, 30.)

Liability of Corporate Promoters—Promoters of a corporation are legally obligated to use the utmost good faith toward the company and the subscribers to its stock. If the promoters undertake to sell their own property to the corporation they are bound to disclose the whole truth respecting it. If they fail to do this, or if they receive secret profits out of the transaction, either in cash or stock, the corporation may elect to rescind the purchase or to hold the promoters accountable for the secret profits. (West Virginia Supreme Court of Appeals, North American Coal and Coke Co. vs. O'Neal, 95 Southeastern Reporter, 822.)

Injury to Inexperienced Miners—When an older and experienced miner is delegated by his employer to instruct and qualify an inexperienced employee for service the employer becomes liable for injury to the latter directly due to negligence upon the part of the instructing employee. Hence, if plaintiff, a miner, was ignorant of dangers arising from the presence of unexploded charges left in coal where he was directed to work, failure to fully instruct him as to the danger and how he might avoid injury was actionable negligence, rendering the operator liable for injuries sustained by plaintiff in exploding such a charge when he struck his pick into the coal. (Pennsylvania Supreme Court, Jelic vs. Jamison Coal and Coke Co., 103 Atlantic Reporter, 300.)

Well Settled Principles Applied to an Unusual Accident—Plaintiff was employed to assist a mine engineer in making certain measurements on an inclined entry. Near the top of the entry was a loaded coal car, held in position by a piece of an old tie set between the end of the car and a tie in the track. The engineer told plaintiff to wait where he was, near the car, until the engineer should make some measurements nearby. Plaintiff sat down in the middle of the track, with his back against the bumpers of the car, and conversed with the mine boss concerning what work plaintiff should do when through assisting the engineer. As the engineer returned, he brushed or stumbled against the prop that was holding the car, resulting in the prop and car being released, and in plaintiff being seriously injured through being dragged in front of the car until it was stopped after moving about 45 ft. Plaintiff sued for damages and recovered verdict for $1200. Setting aside the recovery and ordering a new trial, on the ground that the jury was not properly instructed as to the law of the case, the Kentucky Court of Appeals holds that it was for the jury to determine whether plaintiff was guilty of contributory negligence in sitting in front of the car; that plaintiff was injured while in the line of his duty; but that defendant employer could not be held liable on account of any negligence on the part of the engineer unless that negligence should be found to be gross, because plaintiff and the engineer must be regarded as fellow servants within the meaning of the established rule of law in Kentucky that an employer is not liable for injury to an employee caused by negligence of a fellow servant unless the negligence was gross. (Edwards vs. Borderland Coal Co., 199 Southwestern Reporter, 792.)

Tabulation of Entry Progress

By O. H. Hampsch
Washington, D. C.

The tabulation of the progress of entries in a mine will often prove of much value to the average mine foreman, superintendent or operator. The data in most cases are generally obtained from yardage measurements which the mine foreman or engineer makes at regular intervals.

In the table given below, which may be used as a standard, or a similar table devised to meet any special case, the total entry progress for each semi-month the advance for any particular entry for each month or year, and the total entry progress for the year can be found in a few moments' time.

NAME OF MINE.....

ENTRY PROGRESS FOR PERIOD JAN. 1, 1918, TO JAN. 1, 1919

Name of Entry	Jan.		Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
Main entry (St. N.)	32	37	41											
Main air course	26	33	27											
First east	15	17	16											
Second east	14	20	23											
First west	26	32	37											
Second west	35	22	39											
Third east	20	19	21											
Fourth east	28	25	27											
First right	16	14	5											
Second right	11	20												
Main entry (St. S)	42	47	43											
Main (air course)	49	51	52											
First east	29	31	26											
Second east	34	37	31											
First left	5	11	16											
Second left	21	19	17											
Total														
Total for year														

The arrangement of the table shows an easy method of tabulation which, however, may be adapted or changed to conform to any size of lettering that may be used. The table may be made upon tracing cloth or printed upon ordinary drawing detail paper and mounted upon a cardboard back.

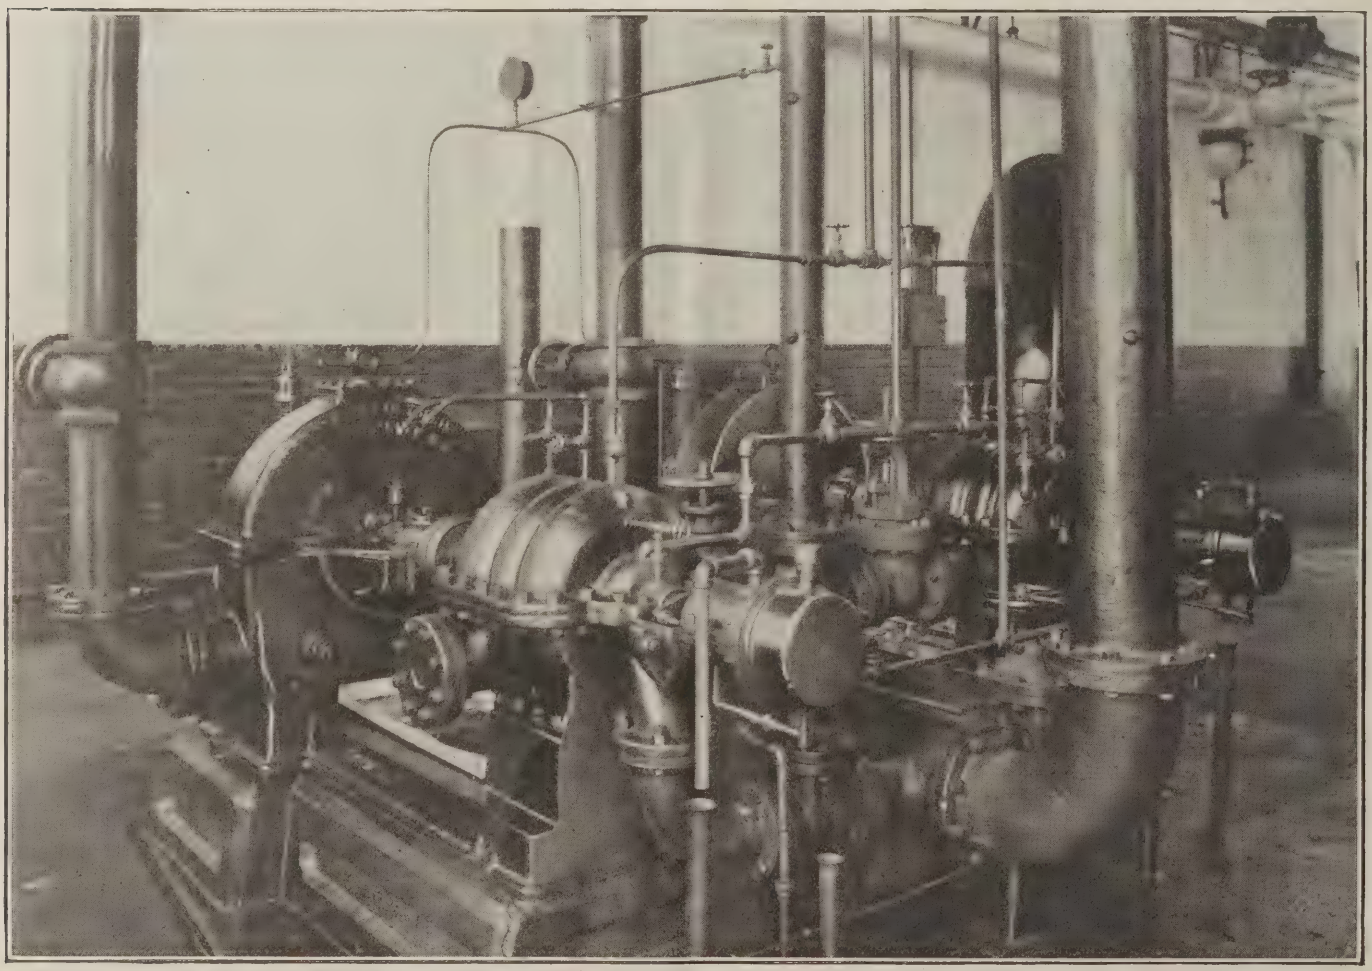
Uses of Peat in Agriculture

The increased use of peat and its products in compounding fertilizers may also afford relief from the present shortage of fertilizing minerals in the United States. Peat has long been used in agriculture in this country, having been either applied directly to the land or used as a filler for commercial fertilizers. In view of the curtailment of the imports of potash and nitrates since the war began and the consequent shortage of fertilizers the time has come when the producers of peat might make better known its value in agriculture.

Analyses of the peats of the United States show that they are very rich in combined nitrogen, from 70 to 85 per cent. of which, a proportion that in some peats amounts to more than 2 per cent. of their dry weight, may be recovered in the form of ammonium sulphate, one of the costly ingredients of modern commercial fertilizers. Peat may also be a source of nitrates. A culture bed of peat, if treated with a dilute solution of ammonium sulphate and then inoculated with nitrifying organisms, is said to yield 0.82 per cent. of nitrates, and with repeated treatment about 4 per cent. It has not yet been shown that this process will produce nitrates on a large scale, but in view of the rare occurrence and present shortage of these salts, which are so essential to agriculture and to the explosives industry, the process strongly invites further and larger experiments.

Peat mull may be profitably employed as an absorbent of the valuable nitrogenous liquids of stables, which are ordinarily wasted. When so used it not only absorbs liquids but checks decomposition and absorbs gases, so that it should be an effective deodorizer and disinfectant. For this use it is superior to lime, ashes, and some of the more expensive disinfectants, and it is a nearly ideal material for use in earth closets and other receptacles for moist waste organic matter.

Peat has also been used successfully in this country as bedding for stock and in compounding stock feed.



Peat has frequently been used as a source of charcoal and coke, of various byproducts from coke retorts, such as those obtained from the distillation of wood and of fuel and illuminating gas, as well as in making paper, substitutes for wood, and packing material. The prospective value of the peat deposits of the country as a source of these products is much larger than their value as a source of fuel.

Information with regard to the occurrence, distribution, and production of peat in the United States will be furnished on application to the United States Geological Survey, Interior Department, Washington, D. C., and information on the use of peat for fuel and other purposes may be procured from the Bureau of Mines, Interior Department, Washington, D. C.

Death of Viscount Rhondda

IT IS hard to know whether Viscount Rhondda was best known here as David Alfred Thomas, leading Welsh coal operator, or as Baron or later Viscount Rhondda, the Food Controller of Great Britain. D. A. Thomas entered closely into our national life, when in 1913 he made two trips to America purposing to secure large holdings in West Virginia. It was confidently prophesied at that time that a large area of coal land in the "Mountain State" would shortly pass into his hands and that, as a result, the United States would enter under every favorable condition into the export business. But the scheme, for some unknown reason, fell through. Mr. Thomas was here again in March, 1914, this time on his way to Canada to provide for the building of a line 1500 miles long, to be known as the Pacific, Peace River & Athabasca R.R., the purpose being to tap the Ground Hog coal fields. Even at that time it does not appear that the proposed West Virginia venture had been definitely given up. The coal properties of that state were not at that time doing so profitable a business as in times past, and the hour was propitious for purchase. Mr. Thomas was much surprised at the low cost of extraction and at the even more remarkable low selling cost. In fact, he had something of much interest to say when in Great Britain as to the great differences existing between mine operating costs in America and abroad.

OPERATOR WHO CONTROLLED THE BRITISH FOOD

D. A. Thomas was born Mar. 26, 1856, at Adare, in Monmouthshire. While this county is Welsh in all its history and characteristics it lies immediately adjacent to the line between England and Wales, and is actually on the English side of the border as England is now delimited. Thomas graduated from Caius College, Cambridge, in 1880, and three years later got his master's degree. He was the son of a colliery owner, but he did not find in that fact a reason for taking charge of the business without first obtaining a practical and underground knowledge of every method of operation.

In 1888 he entered the firm of Thomas & Davey, coal sales agents, and at the same time became member of Parliament for Cardiff, which constituency he served till 1910. In that year he became senior member of his firm as well as managing director of the Cambrian combine and other colliery interests in South Wales. His trips to investigate the advisability of taking an interest in American enterprises followed three years later, but the war prevented his plans from being consummated, and in 1915 he came to America as business agent of the British Government. On this occasion he reorganized the munition industry of Canada, bringing the Shell Committee of the Dominion under direct control of Lloyd George, then the minister of munitions.

David Thomas was on the "Lusitania" when it was sunk, and the exposure is said to have shortened his life. But in the few years yet remaining he had a chance to perform a large service for his country. He was appointed Food Controller and immediately set himself to stop speculation and profiteering in food. He took over all the crops in 1917. Later he announced the formation of an Inter-Allied Food Council to purchase in the United States food supplies for Great Britain, France and Italy in connection with Herbert Hoover, our own great mining celebrity, who, like the mining man of England, had been placed in charge of the Food Administration. Strange to say, Lord Rhondda's thankless job met with generous approval in Great Britain. The more stringent the control the greater the satisfaction. The loose regulation of earlier days was of such a character that long queues of persons assembled at the stores, but after Lord Rhondda regulated matters the ration, while painfully slim, was certain and not so hard to obtain. The situation was indeed quite desperate. The United States had largely suspended shipments of food in order to provide shipping for soldiers, and there was nothing for Lord Rhondda to do but to slip the belt on the portly person of John Bull not one, but several notches. That the latter forgot to grumble and protest is a tribute to the Welsh coal master. Lord Rhondda boasted that he allowed himself less food than he apportioned to the public he regulated.

In fact, there are not a few who believe that his disease resulted from the weakened vitality that was the outcome of his asceticism and devotion to duty. Thus passed away, on July 3, the "British Coal King," to the great regret of his fellow countrymen—an extremely democratic man, and not greedy for honors.

New Classification for Ohio

In order to eliminate the intricacies of the thin and thick vein method of basing prices in Ohio, a new classification for that state has been adopted as follows:

	Run-of-Mine	Prepared Sizes	Slack or Screenings
District No. 1—County of Meigs and Townships of Cheshire and Addison in County of Gallia	$2.35	$2.60	$2.10
District No. 2—Counties of Vinton, Jackson, Lawrence, Sciota, Pike, and County of Gallia except Townships of Cheshire and Addison	3.00	3.25	2.85
District No. 3—Counties of Hocking and Athens, and Townships of Coal and Monroe in the County of Perry and Township of Homer in the County of Morgan	2.10	2.35	1.85
The Bailey Run. or No. 7 Seam	2.50	2.75	2.25
District No. 4—Counties of Washington and Noble, County of Morgan except Township of Homer, and County of Perry except Townships of Coal and Monroe	2.50	2.75	2.25
District No. 5—Counties of Guernsey and Muskingum and Township of Warren in Belmont County	2.25	2.50	2.00
District No. 6—Counties of Holmes, Tuscarawas, Carroll, Coshocton, and Townships of Monroe, Franklin, Washington and Freeport in County of Harrison, and Townships of Washington and Yellow Creek in County of Columbiana, and Townships of Brush Creek, Saline, Springfield, Ross and Knox in County of Jefferson	2.50	2.75	2.25
District No. 7—Counties of Trumbull, Portage, Summit, Mahoning, Medina, Wayne and Stark, and County of Columbiana except Townships of Washington and Yellow Creek	3.00	3.25	2.85
District No. 8—County of Monroe, County of Belmont except Township of Warren, County of Harrison except Townships of Monroe, Franklin, Washington and Freeport, and County of Jefferson except Townships of Brush Creek, Saline, Ross, Knox and Springfield	1.90	2.15	1.90

To the above prices there may be added the 45c. allowance for wage increase if the producing companies are entitled to add such allowance under the President's Order of Oct. 27, 1917.

Lightless Nights Expected to Save Much Coal

The new "lightless" night order is expected to save much more coal than did the one of last year. In fact, all lighting and heating are to be reduced to a war basis. Every effort is to be made to reduce the fuel consumption in office buildings and apartment houses. Eugene C. Eppley, of Sioux City, Iowa, the president of the Hotel Men's Mutual Benefit Association, has been put in charge of the hotel section of the Conservation Bureau of the Fuel Administration. It is expected that a considerable saving of fuel will be effected in hotels by reducing the amount of heat and light used.

Curtails Coal Supply to Breweries

Only 50 per cent. of the average annual requirements of coal is to be furnished to breweries during the twelve months beginning July 1. The average is to be based on the consumption during 1915, 1916 and 1917. The restriction applies to the brewers of non-alcoholic cereal beverages as well as to those which contain alcohol. The regulation allows the operators of breweries to concentrate their brewing at one plant with the right to the same quantity of fuel they would have used had their plants been operated individually.

Margins Set for Run-of-Mine Coal

A separate classification for run-of-mine coal, from which a certain portion of lump has been screened, has been added to the price schedule by the Fuel Administrator. The price of this modified mine-run is not to exceed the Government price applicable for screens plus the following percentages of the margin between the price for mine-run and screening: Run-of-mine passed through 2-in. openings, 40 per cent. of such margin. Run-of-mine passed through 3-in. openings, 75 per cent. of such margin. Run-of-mine passed through 4-in. openings, 90 per cent. of such margin. Run-of-mine passed through 5-in. openings, 95 per cent. of such margin. Run-of-mine passed through 6-in. or larger openings shall take the applicable Government price for run-of-mine.

Dr. Garfield Would Tax Excess Coal Profits

Without expressing any belief as to the accuracy of the Federal Trade Commission's findings in regard to profits in the operation of coal mines, Dr. H. A. Garfield points out that most of the 1916 output was under contract at high prices before the putting into effect of the President's schedule. He admitted, of course, that the price had to be made high enough to meet the necessities of the high-cost mines in the immediate section of low-cost mines. The emergency, he said, made it necessary to stimulate production even if large profits were made by some operators.

Dr. Garfield said the plan of buying the Nation's entire output and selling it at a fixed price to the consumer would not be conducive to maximum production. He suggested that excessive profits could be reached by excess profits taxation, or the Government could buy all the coal, paying each mine a fair profit over its costs of production.

Weekly Production Statistics

Production figures for the week ended June 29 are as follows: Bituminous coal, 12,458,000 tons; anthracite forwardings, 41,641 cars; beehive coke, 604,000 tons; byproduct coke, 496,396 tons. With the exception of beehive coke, production in each case was greater than that of the week preceding.

Bituminous production shot up markedly during the week under review, being an increase of 3.8 per cent. over that of the week preceding, and 7.5 per cent. over that of the corresponding week of last year. In fact, the week's showing is second only to that of the week ended June 15, which surpassed all previous performances in the history of the coal industry in the United States.

The anthracite forwardings were 471 cars in excess of those for the week ended June 22, but still is less than the best performance made in recent weeks.

Shortage of yard labor continues to be by far the serious factor limiting beehive-coke production. For this reason, production during the week ended June 29 was 57,000 tons under that of the week ended June 15. Little difficulty would be experienced, it is believed, in maintaining production above 700,000 tons if the labor could be secured. The byproduct ovens are now operating at better than 90 per cent. of full-time capacity. Car shortage no longer is a factor, and fewer ovens were shut down for repair work. The principal gains were made at Pennsylvania and Alabama ovens.

The figures referred to in the foregoing are estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

New Prices on Coke and Breeze

New prices on coke and breeze have been announced as follows:

Gas coke, in districts where anthracite coal is not obtainable: Run-of-retorts, $5.50; run-of-retorts screened above ¾ in., $6; screened and sized about ¾ in., $6.50; screened and sized, between ½ and ¾ in., $4.50. The lowest published coke freight rates may be added to the foregoing prices.

Gas coke, in districts where anthracite coal is obtainable: Screened and sized above ¾ in., same price as established for stove anthracite in the same locality; run-of-retorts, screened about ¾ in., 25c. less than the price of stove anthracite; run-of-retorts not screened, 75c. less than the price of stove anthracite. The prices are to apply on less-than-carload shipments and on those delivered direct to consumers for household purposes. Coke sold for other purposes is to take the same price as gas coke in the localities where anthracite is not obtainable.

The maximum price for breeze is one-half that established for run-of-retort coke unscreened, made in gas retorts where such breeze is produced.

Coke made in beehive ovens, crushed, over ¾ in., 30c. may be added to the price for 72-hour selected foundry; prepared sizes, clean, dried, screened, under ¾ in., $1 less than blast-furnace coke made at beehive ovens where such coke is produced; breeze, one-half the price of blast-furnace coke.

Byproduct coke f.o.b. cars, over ¾ in., 50c. may be added to run-of-oven price. This is to include all prepared sizes of clean, hard coke over ¾ in. whether crushed or screened by hand or mechanically. Prepared sizes under ¾ in. $1 less than the price for run-of-oven. Breeze, one-half the price of run-of-oven.

Coke produced in Utah, smelting or furnace, $8.50; 72-hour selected foundry, $9.50.

Retailers Must File Coal Reports

Each retailer of coal in the United States must report to the Fuel Administration the amount of his coal receipts, his deliveries and his stock on hand. This plan has been in operation for some time in New England, and now it is to be extended throughout the country. For failure to comply with regulations in this regard, 750 retailers in New England recently were given five days in which to file their reports or have their supply cut off.

Railroad Administration Denies Liability for Coal Lost in Transit

The National Coal Association has taken issue with the stand taken by the Railroad Administration that it is not to be liable for losses of coal by theft when it is loaded in an open-top car or by falling off when it is loaded above the sides of the car. The Railroad Administration takes the position that open-top cars are furnished for the convenience of the shipper and the consignee, and that it should not be held responsible for the many claims which are made for losses in transit from such cars.

The National Coal Association takes the stand, in its representations to the authorities, that it is a dangerous precedent to establish in the minds of people that property being transported by the Government is unprotected by a Government agency. The ruling also is held to influence adversely the loading of cars as heavily as is possible. The association also takes issue with the contention that the open-top car is operated primarily for the convenience of the consignor and the consignees. Numerous examples are cited showing that the volume of coal carried would be reduced enormously if it had to be loaded in closed cars.

Prices Fixed for Charcoal

Prices have been fixed for charcoal by the Fuel Administration as follows: Lump in bulk, 20c. per bushel; lump in bags, 22c. per bushel; screenings in bags, 20c. per bushel. The prices apply on car lots sold to consumer or dealers for wagon delivery. Any commissions are to be paid to the vendors and shall not be added to the price. The bags are to be returnable.

Domestic Consumers to Be Rationed

So rapidly is the demand for coal increasing for war work, that it may be necessary to ration the domestic consumer this winter. Public announcement to this effect has been made by the Fuel Administrator. If it is necessary to apply a rationing system, the amount allowed will be as much as is found sufficient, after scientific investigation, to provide a temperature of 68 deg. This is to be based not on the consumption of last winter, but on the amount which will be required with every possible conservation.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The railroads are supplying the coal mines with more cars. But, given a little imagination, one does not need to be directly informed that coal cars are being more regularly delivered, for it could be deduced readily from the fact that the Fuel Administration has at last appointed a Production Division. So long as the railroads were wholly at fault, such a division was entirely unnecessary and would have been merely provocative of ill feeling. Distribution, therefore, received the undivided attention of Dr. Garfield. Now the burden shifts, and the Fuel Administration is found resting, at least partly, on the other foot. In fact there is a possibility that Dr. Garfield may after a while find himself wholly poised on that little used member.

That this is the case is attested also by the hullabaloo rising from all, or at least most, of the field. One wonders why there is such a loud recrimination, but we have heard the like before. When production is demanded there is sure to be altercation, every one making excuse and no one able to give a reason.

No Reasons Exist for Short-Time Service

The miner is trying to explain that the reason he does not stay underground eight hours is because of this and that. But really the only real reason why he leaves the mine early is because he is unwilling to stay there for the specified eight hours. There is nothing to compel him to come out sooner, except his wish to do so. He should stay underground till the mine closes down. He has no right to say that he will go home because his place is not in shape or the turn is slow. He should persevere the full eight hours. The soldier does not leave the trench because no Germans are stirring and because there is nothing for him to do. He waits till there is something to be done and is there to do it. If he isn't there, he is a deserter and in great need of executive clemency.

Last week we recorded the Alabama comments on the attempts to make the slacker work eight hours. This week the same word comes from Illinois, and the anthracite mine workers are in like manner trying to place the blame on the operators. Of course, the operator is partly to blame, but the miner cannot defend himself by blackening the operator. The miner should stay in his full eight hours, slow or fast turn, whether the undercut is delayed or completed; whether there are road wrecks or the cars come regularly; whether there is water or the road is dry. The mine worker has his duty to perform, and only when he has done it can he begin to load blame on his employer.

Operator Needs Advice as Much as Consumer

But the operator needs quite a little advice, counsel and condemnation. We have seen how in Missouri he has been getting those necessary admonitions from the Fuel Administrator. Between ourselves it seems that the operator who produces the coal needs instruction and pressure just as much as the consumer who burns it. And he is going to get it. He cannot go on inefficiently operating with inadequate equipment and ill-handled plant. If he does not amend he will be shut down by the Administration. At least the action in Pennsylvania in regard to high-cost mines seems to foreshadow that. He is even more likely to be penalized for bad management and consequent inefficient operation than for difficult conditions and consequent high wage rates, for the condition of the coal seam is beyond his control whereas good management really is not.

The disputes now raging are natural, and they will do some good if both parties remember, as Kennamer, Farrington and the presidents in the anthracite region appear to do, that the other fellow's failings don't excuse yours. A man must stand or fall on his own comings or shortcomings and not on the performances of others.

The operators' shortcomings are mostly hard to cure. The miner on rising in the morning may say with full intention, "I will stay in the mine till the last trip tonight," but the operator who on rising says, "I will put 100 more mine cars and two more locomotives on the tracks today, for my men need them," is a fit candidate for a lunatic asylum unless he placed his orders for this equipment some months earlier. The operator's shortcomings, it will be seen, take time, money and the coöperation of other parties as well as mere volition.

Day Laborers More Wanting Than Equipment

Nor is it otherwise with the supply of labor needed to comply with Farrington's demand that every working place be in standard condition. In fact the equipment supply is in some ways in better shape than labor supply. An old mine that is shorthanded, unless repairs have not been kept up and headings have not been extended, is equipped for the tonnage it had before it became shorthanded and therefore should not be in a bad case.

The new mines, especially those run by newly arrived operators without much capital, are the chief offenders in the matter of short equipment. Without capital, without experience and without any claim on the manufacturer such as is derived from past purchases, the new operators are unable to equip their mines properly. Theirs is a nightmare of makeshifts from morn to dewy eve.

While some mines suffer but little for lack of equipment, all mines suffer severely from the lack of labor. If repairmen, water bailers, tracklayers, roadmen, timbermen and rockmen are to be kept available for every job, to be done the moment the work is called for, the roustabout labor supply around the mines must be immensely increased. It will probably pay to supply that labor if the miner will work whenever he has a chance. If he will pitch in as soon as the repairs are made, it will be an economy to accommodate him, if indeed, with our environing labor conditions, that accommodation be possible. But if an omission of the operator that will delay the miner an hour is going to send the miner home for all eight hours, it will not pay the operator or the nation to keep a repair force of this kind in comparative idleness ready to be called into action like the bellboy at the hotel when the clerk cries "Front."

Mine Often Suffers from Under-Supervision

All this argument does not grant the operator a right to deny that the mine is too often a place where under-supervision and under-provision run riot. Too often the foreman waits for complaints when the thing complained of should have had the benefit of his early investigation, knowledge and action. If the miner will work his derndest, there will be profit to the operator and advantage to the nation in providing the miner with the opportunity to put out maximum production, this opportunity being given by a more adequate repair force and a minute and provisional supervision. However, the operator is justified in saying, Where are these additional men to be secured? Mine management, like management in other business, usually retrenches first on repairs, supervision and maintenance. No greater folly can be committed. A bad accident that one man's work might have averted may lay off a hundred men and damage equipment so that the next day's run will be below normal. An hour or two of bailing or ditching, or a day of tracklaying done in time, may give every dayman 25 to 100 tons more output to handle. As the operator has learned in his long idleness, transportation for the material

produced is as important, or more important, than production itself if the tonnage sought is to be obtained.

In the anthracite region, where the hounding of the slacker has been hottest, the defense has developed new forms of recrimination. One notes how wholly different they are to those in the bituminous region. Little talk of slow turn, or flooded places, or time wasted on labor disputes, or loss of time from lack of timber—none of these stock grievances are presented. Probably the anthracite region is better equipped and more effectively supervised than the bituminous region. The anthracite region has almost no new mines and relatively few old mines reopened. It has less miners to tax and test what equipment has been provided. The slacker, therefore, has less to say as to the assistance afforded him, but nevertheless he is busy saying something.

Unsubstantiated Charges in Anthracite Region

Note that the recrimination does not come from the union, but from other less well-informed or less responsible sources. Kennamer and Farrington, in Alabama and Illinois respectively, are meeting criticism with criticism because they have a case. But in the anthracite region the union issues nothing under its name, probably because the criticisms against the operator are less generally justified. The anthracite operator has the equipment, except perhaps miners' dwellings, and he is giving his men favorable conditions for output.

Now what are the criticisms of the mineworkers? In the Shamokin district they say the operators are keeping the flat workings idle because they will not give the men the rate of wages they demand for working in the flat coal. If that action did not lay off any men the charge would be negligible, but the declaration is that there are scores of anthracite men idle in the lower anthracite fields. It is also said that the Delaware & Hudson Co. has laid off 500 men.

These broad statements of a deliberate intention to create an appearance of labor shortage could be quite easily investigated by any of the parties interested, Major-General E. H. Crowder, Dr. H. A. Garfield or William B. Wilson. Doubtless the charge would be completely disproved as soon as inquiry was set on foot by competent authority. So far no responsible organization has given the charge currency. The mine workers also make the claim that the companies want to keep all the men at home who have small families, so that in case of an accident large compensation will not have to be paid to a numerous progeny.

Miners Who Are Only Two-Thirds Citizens

But all these stories of corporational depravity of which we are now hearing on little or no authority are balanced by reports said to be made by inspectors of the Department of Labor, now making a labor survey of eastern Pennsylvania, the region in which the anthracite fields are located. The Labor Department inspectors are said to have discovered that many of the employees work only two-thirds of full time.

Supervising Inspector Walter McNichols is reported to have said that the time lost by miners is one reason why production has decreased. "Flimsy excuses are being offered for laying off," according to McNichols. "I believe that there is enough available labor in the district to get out the coal if it is properly distributed and if every man will do his share and work every day he is able to."

While men are working short time because they do not have to work full time every day or six days a week to provide for a living, the mine workers are asking for a wage scale providing higher wages. At the meeting of the Tridistrict board held July 7 and composed of officials of districts Nos. 1, 7 and 9, comprising the whole anthracite region, the board recommended that the matter of an increased wage be taken up with the coal operators and the Fuel Administration.

Almost everywhere the mines were idle for Independence Day, but on July 5 the men almost without exception returned promptly to work. The two mines of the United Coal Corporation, located at Jerome, Penn., and the mine of the same company at Naomi, Penn., worked on July 4 and produced from two-thirds to three-quarters of a full day's output. The mines of this company had on July 5 a larger turnout and output than is customary on the day following Independence Day.

Give the Front Seat to Men of Jewell Ridge

These men did so well it seems almost unkind to cap their patriotism with an even better performance. The mine workers of the Jewell Ridge Coal Corporation, of Jewell Ridge, Va., near Tazewell, worked on July 4, giving their output to the American Red Cross. The company will give its gross profits and overhead expense for that day to the same end. The owners of the mine proposed a Big Fourth of July celebration with a brass band, but the mine workers opposed the waste of time and money and declared for the operation of the mines. There is a purpose and a vision in the mine workers of Jewell Ridge. The country may well be proud that it has men who will make such sacrifices even without the excitement of a "Drive."

In the Fairmont region of West Virginia the progress of unionism still continues. W. M. Rogers, the president of the West Virginia Labor Federation, claims that 15,000 mine workers have been organized and that by Christmas there will be 27,000 in the union. In West Virginia there will then be a total membership of 44,000 out of a possible 78,000; thus roughly 56 per cent. of all workers in the coal mines of the state will be affiliated with the union. As the Pocahontas region is still nonunion, the organization in the parts of West Virginia that are unionized will then be quite dense, more so than in many states which West Virginia used to regard as in bondage to the union. But then perhaps W. M. Rogers is an optimist and has no sure basis for his prognostications.

All companies in West Virginia employing 20 men or more are required under penalties set forth in Section 6, Chap. 4, of the acts of the Special Extraordinary Session of 1917, West Virginia State Legislature, to report at the end of each week to the Secretary of the State Council of Defense the names of all those persons carried on their rolls who have not been actively engaged at some useful occupation for as many as 36 hours during the preceding week, as provided by the Vagrancy Act. The corporations thus instructed are requested to furnish the Council with the names and addresses of any other "violators of the Vagrancy Law who habitually and without reason work less than full time at their respective employments."

In St. Louis County, Missouri, Fuel Administrator Hodgson says that despite large wages drivers of coal wagons cannot be secured. Half the teams are idle, though the companies have hundreds of orders that they cannot deliver.

Mexicans Must Not Oust American Miners

Some Arizona corporations mining coal doubtless outside that state, presumably in New Mexico, were refused on July 6 the privilege of importing Mexican labor to work their coal mines. Mexicans will be admitted only for farming, railroad labor and, we are told, lignite mining. In the south of Texas is a large body of cannel, with lignite quite close nearby, and this cannel is probably included under lignite in the classification of the Department of Labor, for the basis of the order of the emigration officials is really not the character of the industry but the question whether on the entrance of Mexicans into that industry they will compete with American labor.

Putting Labor To Work Where Wanted

The War Labor Policies Board announced on July 7 that community labor boards would be established. The boards will have general jurisdiction over the recruiting and distribution of labor and will act in coöperation with the United States Employment Service of the Department of Labor.

The boards will enforce in each industrial region the policies of the United States Employment Service. Just as in the military service, the draft boards, under the

Selective Conscription Act, mobilize the army of the conscripted, so in industrial service the local boards now to be formed will mobilize the army of producers. In order that the boards may adequately represent the communities in which they operate, the employees and employers will each select representatives.

Community labor boards consisting of one representative of employers and one representative of employees with a third representative of the United States Employment Service are now being established wherever the industrial situation justifies it. While the final appointment of the membership of boards will be made by the state directors of the United States Public Service Reserve, the nomination of the representatives of industrial management will be requested from chambers of commerce and manufacturers' associations, while the state and city federations of labor will be asked to name the labor members. The third member of each board, to whom will fall the honor of presiding, will be in every case a representative of the United States Employment Service.

The community labor boards will not only assist in providing labor when there is a call for it, but will decide upon the relative needs of the different industrial establishments in the territory over which they have supervision and where the supply is less than the demand they will prorate the existing reserve.

Miners Quarrel and Quit Work

One hundred and fifty miners employed at the Tuxhorn mine, Springfield, Ill., returned to work Monday after having refused to work for several days on account of a racial clash between negroes and foreigners. The negroes predominate in the union and for five years Robert Jackson, a negro, has been the president of the local. There was an election recently and Jackson was reëlected. White members of the union complained that the election was irregular.

Later the factions almost got into a battle, and several were arrested for carrying concealed weapons. United States District Attorney Knotts took a hand. He talked to the leaders of the factions and the men agreed to return to work Monday if he would be at the mine to prevent trouble. He was there accompanied by a deputy United States marshal and work was resumed without trouble. The controversy is to be referred to the state officials of the union.

A committee of the union, in a public statement, blame the trouble on a socialist who has agitated opposition to Jackson among the foreigners. Charges which were filed by him against Jackson were dismissed by the district board of the United Mine Workers as without merit. Jackson, according to the statement, has been zealous in the interest of Liberty Bonds and the Red Cross.

Last week on pp. 24 and 25 under caption "In Illinois, Union Backs Minerettes" *Coal Age* referred to the strike at the Chicago, Wilmington & Franklin Coal Co.'s mine at Thayer, Ill. Apparently the manager of the mine, John Marland, denies the statement that the fuss originated in the refusal of the company to hire a Virden woman, the wife of a soldier, as weighmaster at the mine.

He puts the blame on a personal row between Riva and an official of the United Mine Workers of America. Whatever was the real cause, 600 men were rendered idle for two weeks. On June 28, however, they voted to return to work pending a settlement. Apparently the surface men were the persons most aggressive in declaring and maintaining a strike.

Mine Workers "Pass the Buck."

Frank Farrington, president of the Illinois District, No. 12, has written to the officers and members of the union directing their attention to the fact that by reason of a recent order issued by the United States Fuel Administration, mine operators are required to make a daily labor report to the administration, detailing the number of men employed, the number in the mine on the day of report, the potential working hours, the hours actually worked, the hours lost and the percentage of the potential time lost. There is reason to believe, he says, that although designed primarily to increase coal production, these reports will be used to help search out idlers and to assist in the enforcement of the "work or fight" rule.

"The report requested by the Fuel Administration will," he says, "create an erroneous impression and one that is apt to do great injustice and injury to the miners. And it will do it in this way: The mine owner is required only to show the aggregate amount of working time lost by the miners and is not obliged to show the reason why it was lost. Many men may be idle or have to return home after having reported for work, on account of having no coal cut or by reason of squeezes, fires, gas, water, falls, lack of timber or track, or because of disabled machinery necessary to serve their particular section of the mine, or for many other reasons over which they have no control.

"A report will be made merely stating that they have been idle all or part of a day and they will accordingly be classed as idlers or industrial slackers. Therefore, it devolves upon us to devise some measure of self protection and to that end I suggest that our men insist that their working places be kept in a workable condition, insofar as the mine management is responsible for them. Where men are prevented from working eight hours, as is required by our joint agreement, the cause of their inability to work the specified time should be immediately reported to the mine management."

Farrington declares that local rules which are in violation of the joint agreement and which restrict the output of coal must be abolished unless failure to do so can be justified in the eyes of the boys "over there" and in the eyes of those who have given them up to go "over there." Every member of the union, he says, should and must work eight hours a day and six days per week when given the opportunity to do so. So serious and solemn is the obligation, he says, that he doubts if even a stoppage of work to say farewell to conscripts leaving for military service can be justified unless only the relatives and very close friends and intimate friends of those who are leaving quit work for that purpose.

[Our correspondent at Washington informs us that the Fuel Administration is not requiring a report such as is here described —Editor.]

Department to Help Only War Industry

The Department of Labor authorizes the following announcement:

Only manufacturers engaged on war contracts and employing over 100 workers will be required to obtain their unskilled labor through the United States Employment Service of the Department of Labor by the ruling which goes into effect Aug. 1. So much uncertainty as to the scope of the new labor-recruiting policy has been shown in inquiries received by the Department of Labor from employers not engaged in war work that the Department today announced the exceptions under which private recruiting of labor may still be carried on:

"Nonwar industries must not offer superior inducements, prevent the transfer of workers urgently needed for war production, nor in any way attempt to compete with the government for labor.

"The following five classes of labor need not at the present time be recruited through the United States Employment Service, although of course the machinery of the Employment Service is available to all employers needing these classes. (1) Labor which is not directly or indirectly solicited. (2) Labor for railroads (except in so far as the Director General of Railroads has already or may in the future require that recruiting shall be exclusively through the United States Employment Service.) (3). Farm labor—to be recruited in accordance with existing arrangement with the Department of Agriculture. (4) Labor for nonwar work. (5) Labor for establishments the maximum force of which (including the additional number recruited) does not exceed one hundred employees."

EDITORIALS

Increased Postage Rates

NEW rates of postage on magazines became effective July 1. These increases are material, particularly at distances of more than 300 miles from the place of publication. The obvious step would be to raise the subscription rates in distant zones to cover the added postage.

For the present, however, the publishers of *Coal Age* have decided not to increase the subscription price, trusting that in the interests of national unity Congress will before long repeal the zone law and revert to the universal flat-rate system. Zone rates on magazines obtained in this country before the Civil War, but were abolished in 1863.

The publishers hope that they will not find it necessary to increase the cost of the paper to its readers.

Vein, Seam, Horizon, Blanket or Bed?

COMMON PARLANCE in the anthracite region describes the coal deposits as "veins." In the rest of the country this usage is regarded as grossly incorrect, and there is no question but a strict use of words would forbid us to name a deposit extending in all directions over a plane after anything as narrow and ramifying as a blood vessel, even though early in the history of coal mining coal was believed to worm its way through the rocks somewhat like a vein of gold-bearing material.

But the purists of the bituminous region do not better conditions much by using the word "seam," for the seam of one's coat is narrow also. In fact, neither "vein" nor "seam" expresses the meaning as well as "bed." It may be objected that a bed is always level, but then the coal bed was likewise level when deposited; and a folding bed does not cease to be a bed after it is upended. If, then, we would be accurate, we must term the coal deposit either a "stratum" or a "bed."

Where the coal is in a reasonably horizontal plane, the word "horizon" might be a fair substitute for the names now in use, but that expression is usually applied as including far more than a single bed, and, moreover, horizontality is usually one of the few qualities that a geological horizon is unable to preserve. For this reason the word is historically correct perhaps, but nevertheless misleading.

Furthermore, "horizon" is one of those rare locative substantives. It does not name the bed so much as express the locative quality. "Horizon" bears to "bed" the same relation that "location" bears to "lot." We talk of a pleasing location, but not of a location measuring 50 x 100 ft. So we talk of a coal horizon, but the accepted diction forbids us to say that a certain coal horizon is 3 ft. thick. "Horizon" is purely a locative word, expressing the relation between one bed and those above and below it.

One unusual word perhaps describes a coal bed better than any other. The idea of a "bed" in the mind of an ordinary person is of something about one-twentieth of a diameter thick, for the upholstery of a bed is about one-twentieth of its longest dimension. A blanket, on the other hand, is many times as long and wide as it is thick. The word accordingly helps to visualize the broad extent of a coal bed. Moreover, a blanket is readily and usually folded, thus recalling the nature of a coal stratum.

In fact, if one would convey to the man who does not understand the occurrence of coal and the true nature of that occurrence, the use of the word "blanket" will aid better than any other to make it clear. However, here again we are troubled, for our metal-mining friends will have it that a blanket deposit is one made after the strata in which it is found have long ago solidified.

If, therefore, one would avoid a controversy, the word "bed" or "stratum" had better be used exclusively, and the latter word, however accurate, also eschewed if the speaker or writer would prefer not to be thought pedantic. But after all, why be so careful in diction as to exclude "vein" and "seam"? They are based on imperfect analogies, it is true, but are not all analogies more or less incorrect and inadequate? Long use justifies a continuance of the customary word and skillfully hides the false ideas which gave currency to the ill chosen terminology.

He Who Saves Serves

WE PRINT a poster this week on the buying of "man-size bonds." The nation expects of the soldier man-size service, and of every man, woman and child man-size saving. If we ceased to buy so many trinkets and furniture, and no longer hustled around to entertainment that doubtfully entertains; if we embraced the "simple life" that Charles Wagner so eloquently advocated, it would be possible for us all to save more than we do. Large production and limited spending will put our civilian population on a war basis, and what reason is there that we should not all be conscripted for some kind of service?

No one knows how much we shall be asked to subscribe to the Fourth Liberty Loan. The poster has assumed eight billion dollars as the amount required; it may be more, it may be less. But if it is eight billion, then each earner has $200 to contribute to that fund. If we pay the subscription at the rate of $4 per week, we shall be a year meeting the liability. Why not hurry matters along by clearing up the payment in six months, so that we shall meet the next loan with a clean slate and perhaps with a few dollars of savings? A good way is to pay 10 per cent. of the undertaking every two weeks. The loan is then completely cleared in five months, and the subscriber is ready to pay a small amount down when the next loan comes along.

The past has seldom done due honor to the saver—the man who expends less than his labor produces. Not that monuments have not been erected to him. No form of patriotism has been more conspicuously monumented. But on these monuments there is usually no name. Still more seldom is a sentence of commemoration or honor written large upon them. But monuments they are, though they honor the unknown. They are memorials of the savers. They are the railroads, the bridges, the factories, the farms, the houses, the mines, the dockyards and the machinery—the implements by which are made possible easy and highly productive toil. It is the possession of these implements that has made possible big product for normal labor, and has consequently enabled the workingman to buy more for his day's work.

If we spent all we made, we would have none of these implements of economic production. They exist alone as the balance between receipts and outgo. They are the product of the abstemiousness of the human race. We hear too much about the miserly. It is true that there is at times a thrift that is not a virtue, but without thrift the world would be a wilderness. What we have and what we are is the outcome of our well-ordered thrift. Let those who brag they have never saved a cent remember that it is despite them, and not by them, that the world has reached its present stage of well-being.

Canal Route for Illinois Coal

DURING the 1917 session of the Illinois legislature, a bill was introduced outlining a plan to open up the Big Muddy River and convert it into a canal to barge coal to the Mississippi. A bill along these lines passed the Illinois senate in which an appropriation of $1,000,000 was made for the purpose noted. It undoubtedly would have passed the House, but at this point the governor of the state requested that further action be deferred on account of conditions such as exist today. In time it is expected that the bill will go before Congress.

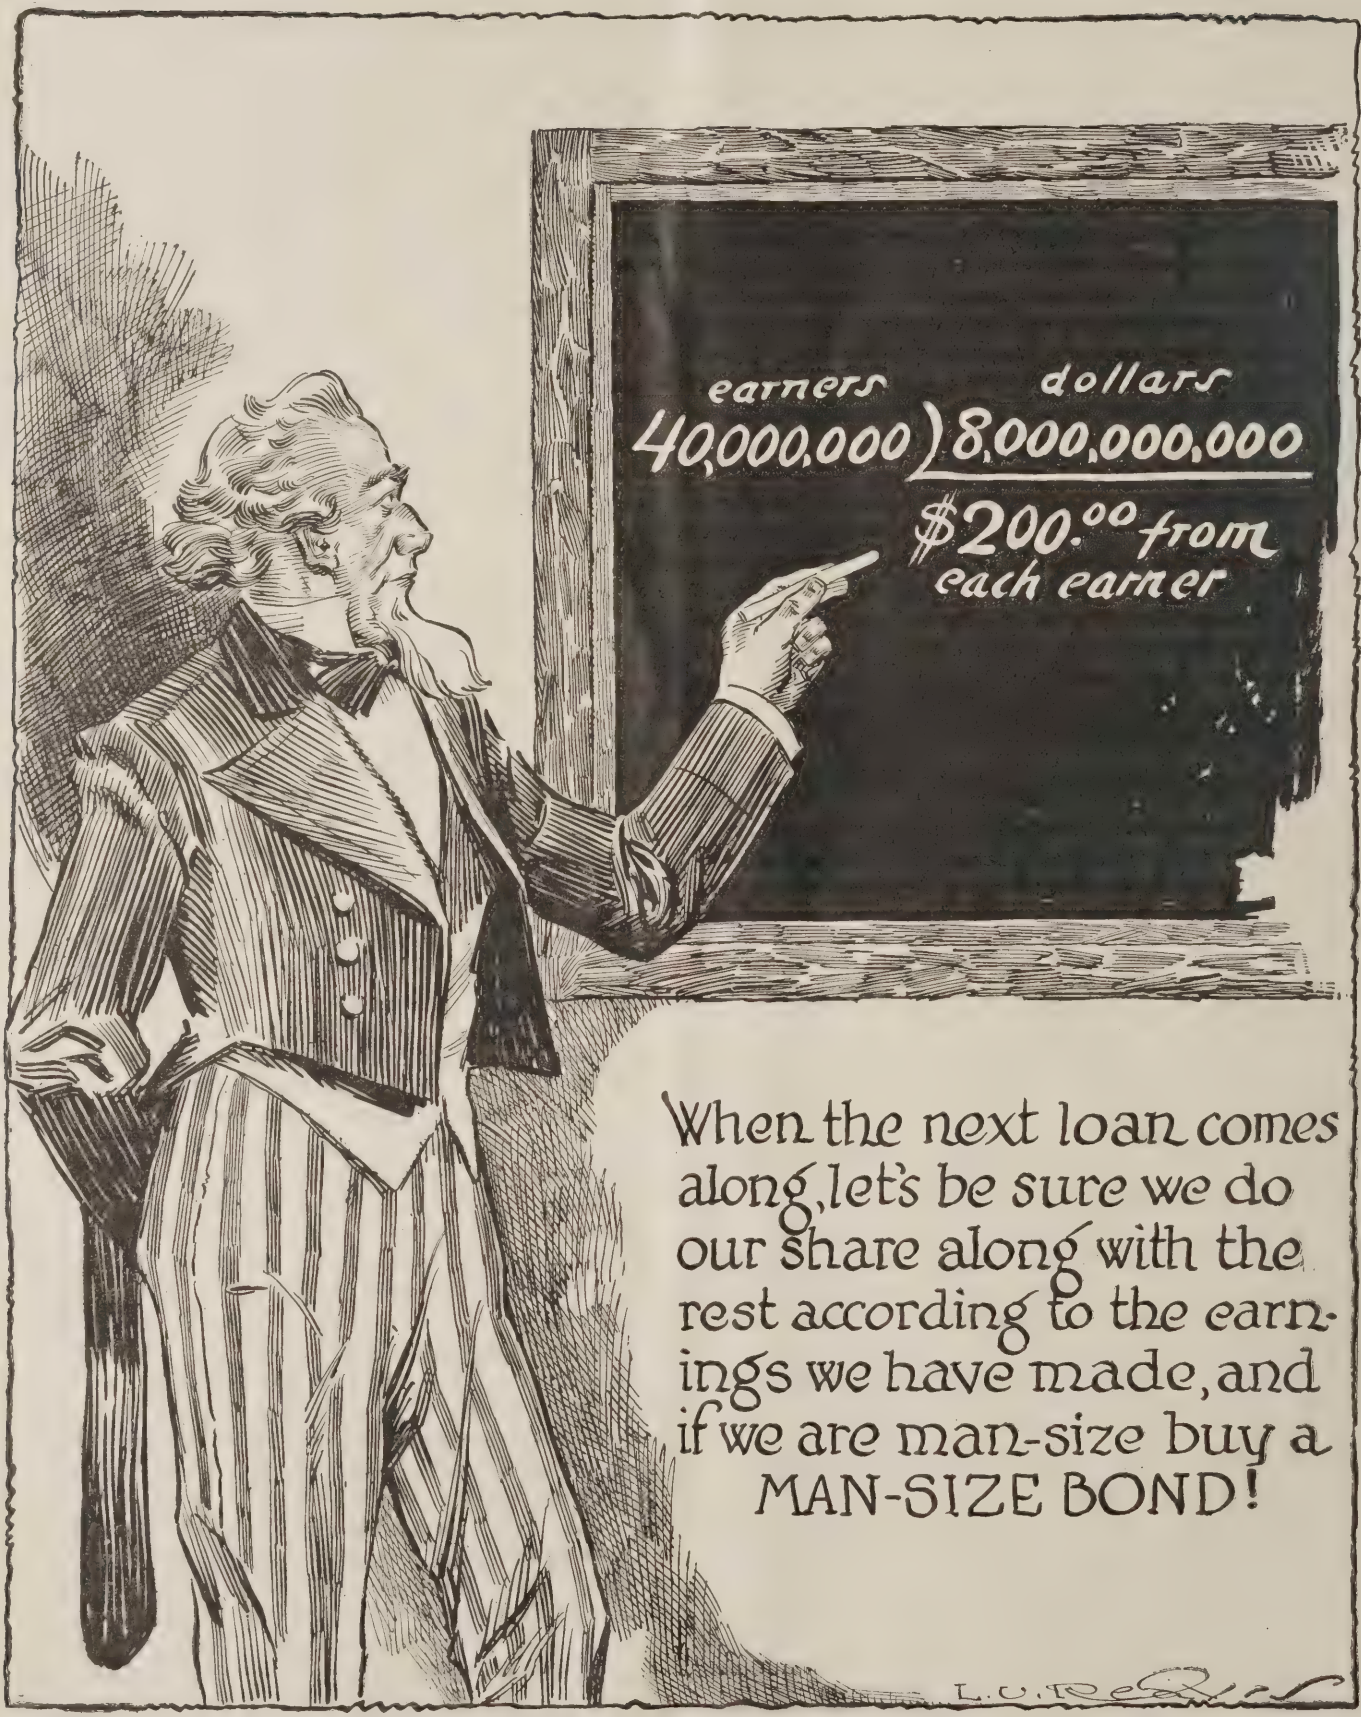
This project includes dredging and straightening the Big Muddy River—in other words, to canalize it from Plumfield, or a little above, in Franklin County, to the Mississippi River. Locks are called for along the lower stretches of the river, and a new channel is planned from Sand Ridge to the mouth in Jackson County, some 50 miles above the junction of the Ohio and Mississippi Rivers. The United States Geological Survey has been over the Big Muddy territory, and both Federal and state engineers have pronounced the project entirely feasible.

Even if the Big Muddy project had gone through, it would have had to give way to the priority claims of a similar scheme with reference to the Illinois River, which is being deepened from its mouth to a point where the Chicago drainage canal empties into it. The southern Illinois coal field is exceedingly active, especially that portion tributary to the Big Muddy, and water transportation in this section would materially relieve the railroads. The demands for the Pittsburgh coals are so heavy at home, even if it were not for the zoning requirements, that other coals would have naturally tended to replace them. Franklin County particularly has stepped in and filled orders with coal which has done the work formerly claimed as the special field for western Pennsylvania fuel. Screenings, the great handicap to production at many Illinois plants, are especially applicable to the needs of cement and brick plants among other uses, and competitive transportation might act as an incentive to greater activity on the part of the railroads of the state, as regards the prompt handling of this grade of fuel, than has been shown in the past.

The initiative in matters similar to the Illinois and Big Muddy River projects generally originates locally, and such projects have sometimes been associated with "pork barrel" scheming during the period when the claims of the bill for recognition were being presented by congressmen at Washington. Many worthy projects have thus suffered changes due to political manipulation. A systematic plan covering the whole country has been urged many times to be handled by an Inland Waterways Commission, and the Big Muddy and similar projects might receive earlier and freer development under such guidance.

Correct Sphere of the "Country Bank"

BEFORE the war, we rarely, if ever, heard of the "wagon mine," much less of the "team-track mine"—not that these institutions were unknown. Whenever industry booms and the coal industry suffers from lack of cars, owing to the appropriation of coal cars to other uses, the wagon mine has loomed up large and made unhappy times for the railroads.



But heretofore it has been known as the "country bank." It took this, the greatest of all coal shortages, to give a new name—two new names in fact—to these mines in miniature. Country bank seemed too rustic an appellation for such a profitable and expanding venture.

The country bank, however, has had an honorable past, which it should not disguise under a new name; it has supplied coal in the winter directly to the purchaser, and so has saved railroad equipment; it has enabled the mines to meet the peak loads of the winter; it has given cheap coal to the country dwellers, and given it without the inconveniences of long storage; it has furnished winter work to the farmer and his team; it has furnished coal for the burning of lime, thus providing for the ready fertilization of the farmers' fields.

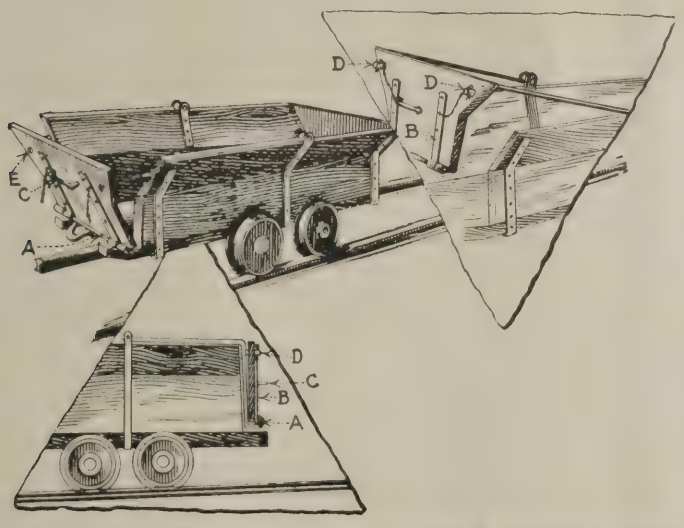
The country bank has also served as a school of apprenticeship to the regular coal business. The less fortunate farmers were digging coal and selling it long before the regular coal mine entered the territory, and even after its entrance, and these farmers later entered the regular mines. The wagon mine was also the grand prospector for new coal lands. It alone gave a broadly correct idea of the value of the coal territory, of its "wants," its dips and its coal thickness and quality.

The country bank has done, and will continue to do, a good work. With motor trucks it will probably supply coal over larger areas than ever before, and at a lower price. The burden imposed on the farmer in buying a motor truck, such as all should have for their regular agricultural work, will be lightened by the assurance that the purchaser will thereby be enabled during the winter to enter the coal trade under favorable conditions.

A Problem in Division

One Liberty Bond in every issue is like one rifle shot in every battle—better than nothing, of course, but sure not to end in victory.

The soldier uses all his cartridges and puts them where they will count. Are you doing the same with your dollars?



DISCUSSION BY READERS

Mine-Car Door

Letter No. 4—Kindly permit me to submit my solution to the inquiry of V. C. Robbins, *Coal Age*, June 1, p. 1031, together with a rough sketch illustrating the manner in which I think the car we are using, generally, with the self-dumping cage, can be altered so as to permit of its being loaded conveniently in a thin seam of coal, by dropping the end-gate, as suggested by Mr. Robbins.

The sketch shows the end-gate of this car mounted on long hinges made of bar iron and bent at right angles so as to permit the long arm of the hinge to extend over the top of the car, at each side, the hinge being pivoted at the center of the car and the shorter arm being bolted firmly to the end-gate. This arrangement permits the door to be raised automatically by the door-lifter, at the top of the shaft, coming in contact with the iron lug *C*, which is shown bolted to the end-gate at its center.

My suggestion is, that, in order to enable the end-gate or door to be dropped to the floor and permit coal

MINE CAR FOR THIN COAL AND SELF-DUMPING CAGE

to be loaded into the car, in a thin coal seam, the door should be mounted on hinges *B* turning on an iron rod *A* supported by the two bent hinges previously mentioned. Instead of the door being bolted to the two bent hinges, as has been described, it is now made to swing freely on the iron rod supported by them. When the car has been nearly loaded, the door is raised and made fast to the bent hinges by means of a strong bolt *D* fastened to each hinge. Each bolt passes through a hole *E*, in the door, and cotter-pins hold the door in position, as shown in detail in the figure.

I believe this arrangement will allow the car to be loaded in the manner described by Mr. Robbins, and that when loaded and hoisted in the shaft on a self-dumping cage, the door will be lifted automatically in the same way, as when it is bolted firmly to the bent hinges, as in the car now in use in this state.

Scammon, Kan. ROBERT LAWS.

Care of Coal Cutters

Letter No. 1—I was pleased, in reading the article on the "Care and Management of Coal Cutters," *Coal Age*, June 15, p. 1108, to note the many good points brought out and which are worthy of the careful attention of all operators and machine runners.

It seems to be the idea of the average machineman, at least here in Illinois, that all that he is required to do is to cut the coal. He does not consider that he is the least responsible for the care and proper use of the machine he is running. If a breakdown occurs, he at once calls on the repair man to remedy the trouble, while he idly awaits his coming. In most cases, the breakdown is due to the man's abuse of his machine. He either does not know or does not care to use ordinary precautions to prevent the mishap.

Some time ago I worked in a mine in the southern part of this state where only Sullivan short-wall machines were used. At that time, I was loading coal and working extra on machines. It was almost impossible to get eight hours' work out of any machine in the mine, owing to the mistreatment the machines received. The company had changed machine bosses so often that the machine runners did about as they pleased, until a boss was found who had worked formerly for the Sullivan Machine Co., in the capacity of demonstrator.

COMMON ABUSE OF COAL-CUTTING MACHINES

As an example of the abuse of the machines, let me cite a single instance where a machine runner, going from one place to another, ran past the switch. Seeing his mistake he promptly shut off the current, threw the reverse lever over, and again turned on the current while the armature was running at a high rate of speed. This was a common practice of machine runners, who were in the habit of "plugging" their machines in this manner.

On taking charge, the first step of the new man was to lay down a set of rules and give notice that a severe penalty would be imposed on anyone violating the rules. This put an end to most of the switch trouble. The new man kept a separate expense account for each runner he employed. If the account ran too high he moved the man to another job and put another man in his place. It was not long before a great change was observed and the management could depend on getting a full day's work out of each machine, barring unavoidable accidents.

In addition to his supervision of the men, the new boss studied carefully the nature of the coal and experimented to find the kind of bit that would do the best

work. He found that the old pick-points were not adapted to the work, as they cored badly. In their place he adopted a chisel bit and got better results.

The man used his head and educated his runners to do the same, and it was not long before there was a vast improvement in the machinework in that mine. Some men he found whom he could educate, while others he was obliged to change, with the result that he soon had as competent a set of men as could be found in any mine in the state.

For a considerable period the electric current at this mine was particularly poor. The new man investigated this matter also and made alterations in the wiring and bonding of rails. The result was such an improvement that it was found unnecessary to get another generator, as the company had contemplated. On my last visit to this mine, I was told that if one generator gave out at any time, it was possible to continue work with the smaller generator, until the larger machine could be repaired. Under the old state of affairs, this would have been impossible.

All of these improvements the man has accomplished in about twenty months. In that time, he has saved the company a year's salary, in the repair of machinery, by picking out of the scrap heap parts that could be used again after being worked over. My belief is that if all machine bosses were first-class, competent men and would lay down rules to guide the men in their charge, the result would be a great surprise to the company who employed them and the cutting down of the expense of operating.

Like the man I have mentioned, a machineboss should have had previous experience and understand thoroughly the difficulties to be encountered in cutting coal and the abuses that the machine runners are prone to inflict on their machines. MACHINE RUNNER.

Nashville, Ill.

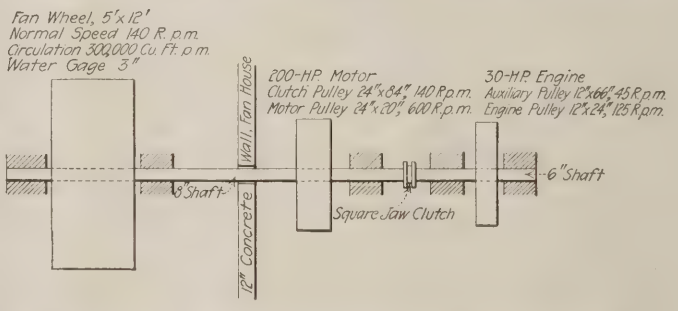
Selecting Mine Foremen

Letter No. 1—I have been an interested reader of H. E. Gray's letter, *Coal Age*, June 1, p. 1030, and was particularly impressed with his description of the kind of man some operators would select to take charge of their work.

The reference made to the choice of "a young man who has the pep, push, vigor and vim to make things go," and the suggestion that if things go wrong the only thing to be done then is to get a new man, caused me to wonder who the next man would be for the job, and whether the choice would fall on the same type of young man who has the required push and who can, no doubt, make things go; or whether the lesson taught by the failure of such a one would cause the management to look for an older man who has the necessary experience and qualifications to insure success.

There is no question but that older men holding positions as mine foremen frequently fear that young men working under them will climb into their place. With this fear in their hearts, they watch every opportunity to discourage their efforts and work. This is liable to occur when the man in charge has neither the judgment nor qualifications that fit him for the position he holds. Recognizing the ability and ambition of the younger man, the temptation is strong to put every impediment in his way. I do not mean to say that this is the disposition of mine foremen in general, and am glad to state that it is the exception rather than the rule.

Because a man is older is no proof that he is better qualified to fill a responsible position than a younger man, but the test is in the qualifications which each may possess. An instance that came under my observation and which illustrates this point is that of a mine foreman who was employed by a large company. This man was 45 years of age and had plenty of pep, push, vigor and vim. He certainly made things go, but I am sorry to say they did not go right, and the company were obliged to seek another man for the place. The one then chosen was a young man, but he had the qualifications that insured his success, and from that time things moved smoothly at the mine.



In closing, let me say that favoritism should be set aside entirely in the choice of men for responsible positions. The choice should depend on qualifications and fitness for the position, whether the man be young or old. Only in this way can results be obtained. The frequent change of mine foremen mentioned by Mr. Gray, is, in my opinion, a great mistake. Change should only be made when things are going wrong and it is unquestionably the man's lack of qualifications, in this case, that is to blame.

Sugarloaf, Penn. JOSEPH LAWRENCE.

Auxiliary Power To Drive Fan

Letter No. 1—Referring to the inquiry, *Coal Age*, June 22, p. 1173, relating to the installation of an auxiliary engine to be used to drive the mine fan, in case of emergency, permit me to give my own experience in respect to the same problem encountered in the development of a large mine.

After a thorough investigation of gasoline engines and the storage-battery problem, I concluded to use a

SHOWING DETAILS OF SHAFTING FOR MOTOR AND ENGINE DRIVE

steam engine as an auxiliary drive, by installing, at the wash house, a boiler of sufficient capacity to drive the fan.

In the case presented in this inquiry where a 75-hp. motor is used to drive the fan under full load, an engine developing 10 or 15 hp. would, in my opinion, be sufficient to create the necessary ventilation to keep the air current moving, assuming that when the power is cut off the mine ceases to operate, and the only object of maintaining the ventilation is for the safety of the mine.

The installation to which I refer here is illustrated in the accompanying figure, which shows a clutch pulley

driven by a 200-hp. motor. The engine drive is disconnected by a positive square-jaw clutch. In the ordinary method of operation, the clutch pulley is thrown in and the short shaft, which carries the engine-drive pulley stands still under a tight belt. The moment the electric power is thrown off, or fails, the clutch on the clutch pulley is disengaged, the jaw clutch thrown in, and the engine started.

In this particular instance, a boiler of 150-hp. capacity is installed in the wash house and banked with 75 or 80 lb. of steam, which is more than sufficient to operate the engine, and drive the fan at a speed of 45 r.p.m., which will produce about 70,000 cu.ft. of air per minute, the normal speed of the fan being 140 r.p.m. If only low-pressure steam is available, the size of the engine has to be correspondingly increased; but it is considered far more reliable to depend on a steam engine than to rely on an internal-combustion engine, especially since the engines now-a-days are built for lower-grade fuel and require from 3 to 5 min., under the most favorable circumstances, for starting.

CARL SCHOLZ,
Chicago, Ill. General Manager, Valier Coal Co.

Straightening Brittle Mine Rails

Letter No. 2—Relative to the inquiry of "Doubtful," *Coal Age*, June 29, p. 1213, I, too, have been eagerly scanning subsequent pages in the hope of learning the truth of the former correspondent's contention that brittle rails can be straightened without being annealed by heat or taken out of the mine. Perhaps our friend has discovered that he has something valuable up his sleeve, and is now unwilling to give out the information.

It occurs to me that it may be possible, through the application of electricity, to anneal the iron in some manner, since the electric return acts upon the rails to make them brittle. I have had some experience straightening brittle rails or rails that have been subject for some time to the action of the electrical return; and I am satisfied that the difficulty of straightening these rails is often greatly magnified through prejudice.

In straightening several tons of bent rails, weighing from 16 to 35 lb. per yd., which had been subject to long continuous use on main haulage roads and for gathering cars at the face, I have lost very little through breakage of the rails. When having occasion to straightening rails of this character I have been told, in quite a contemptuous manner, that "nine out of every ten will break," while the result showed that the reverse was nearer the truth, and perhaps one in ten would be broken.

Of course, 30 and 35-lb. iron breaks more easily than lighter rails. It would be even more difficult to straighten rails above 35 pounds in weight; but I believe that, in the average mine, there is not the same occasion to straighten the heavier rails, because they have been subject to such severe usage on heavy hauls and are so badly worn that they are seldom fit for further use.

On the other hand, it does seem quite a difficult feat to bend straight rails that have been rendered brittle through electrical action; as, for instance, where it is desired to lay a switch off an electric-locomotive haulage. But, even then, I have had little trouble from breakage in bending such rails. One should, however, be very careful in straightening rails that undue strain may not be applied at certain points in the curve. Take the precaution to move the bender after every three or four turns, so as to insure a more uniform stress throughout the length of the rail and give time for adjustment.

Thomas, W. Va. TRACKMAN

Interpreting Mining Laws

Letter No. 6—It is not surprising that we still hear the question asked, "What is the meaning of the word 'miner,' as used in the Anthracite Mine Law of Pennsylvania, in reference to the nature of a man's employment in the mine, before he can receive a miner's certificate." Ii is well known that, for a long time, there has been much dissatisfaction in respect to the requirements of what is termed the "Miner's Certificate Law," and complaints are frequent.

Section 1 of the Act of July 15, 1897 reads as follows:

> Sec. 1. Be it enacted, &c., That hereafter no person whosoever shall be employed or engaged in the anthracite coal region of this Commonwealth, as a miner in any anthracite coal mine, without having obtained a certificate of competency and qualification so to do from the "Miners' Examining Board" of the proper district, and having been duly registered as herein provided.

The qualifications of applicants for miners' certificates are stated in Sec. 5 of the same Act which reads, in part, as follows:

> All persons applying for a certificate of competency, or to entitle them to be employed as miners, must produce satisfactory evidence of having had not less than two years' practical experience as a miner, or as a mine laborer in the mines of this Commonwealth, and in no case shall an applicant be deemed competent unless he appear in person before the said board and answer intelligently and correctly at least twelve questions, in the English language, pertaining to the requirements of a practical miner, and be properly identified under oath, as a mine laborer, by at least one practical miner holding a miner's certificate.

The requirement that a man must work in the mines of Pennsylvania, as a mine laborer before he can apply for and receive a certificate authorizing him to mine coal, or work as a miner has not only imposed a grievous hardship upon many competent miners but has been detrimental to the mining service in the state. It has prevented many skilled workmen from foreign countries from entering the mines, as they often object strongly to spending two years laboring for men who are probably not as well qualified to do the work as they are themselves. Many of these men are perfectly competent to do the work as they have had a great deal of experience in coal mines in foreign countries.

Referring to the opinion of the state's attorney general that any one employed in underground work in the anthracite region is a miner, it may be stated that the definition of the word "miner," as given by the attorney general will hardly agree with that given in the Act of June 1, 1915, which reads:

> The term "miner" means the person who cuts or blasts coal or rock at the face of a gangway, airway, breast, pillar or other working place; also any person engaged at general work in the mine and qualified to do the work of a miner.

A man could hardly be "qualified to do the work of a miner" without having served his time as a miner's

laborer at the working face; and, by the previous act which is still in force, he must do so in the mines of Pennsylvania. FRANK HALL, Deputy Chief,
Harrisburg, Penn. Department of Mines.

The Mining Situation

Letter No. 2—At the present time, it would seem as if the Nation was at its wits' end, so to speak, to know what methods to adopt or how to proceed to increase the production of coal and secure a maximum output from every mine, which is necessary for the successful prosecution of the war. There is no doubt that coal operators, one and all, will welcome any suggestion that will help them increase their output, provided that the things suggested are practical.

One point appeals to me as being important enough to be borne in mind. Many coal mines are largely dependent upon coal-cutting machines and other necessary mechanical equipment. Should the Government find it necessary to commandeer the steel production, it would seriously embarrass the operation in many mines, as operators would then be unable to secure the prompt delivery, if at all, of such equipment as they require.

NEED OF LABOR-CONSCRIPTION

In this emergency, more dependence will have to be placed on increasing the man power in coal mining. It is true that we have many able-bodied and experienced coal miners who might justly be called slackers, for the reason that they work but half the time and lie idle the remainder. This may be attributed to love of pleasure, laziness or booze; but whatever the cause, the effect is the same as far as the production of coal in the mines is concerned.

I want to suggest that the time has come to adopt a law that will compel this class of slackers to continue at their work. Compare such a condition with that which exists in Germany, where every man is compelled to do his part and there is no opportunity to shirk. Here is a virtue that it would be well to emulate, though one of a common enemy.

It would appear that the only way to round up the class of slackers to whom I have referred would be by the enactment of a law as drastic as that of the selective-draft law. There is no reason why a labor-conscription law should not prove as great a boon to the coal industry as the selective-draft law has been to our army of fighters. Where individuals, whose labor is necessary for the welfare of the country, do not realize the seriousness of the present mining situation, they should be brought to feel their responsibility in the great cause by drastic action of the Government. Every man should feel it is his duty to work every day when that is possible.

OTHER CAUSES OF REDUCED COAL PRODUCTION

One source that lessens the production of coal is the celebration, by foreigners, of the large number of national holidays they have been trained to keep in their own country. But no man can serve this country loyally and continue to lay idle, on such account, at this time. No church, lodge or society can consistently and with loyalty insist on its members observing their customary holidays, as before the war.

Another unquestioned source of trouble is the booze habit that prevails too largely among the mining classes. Where this habit exists it should be controlled so as not to interfere with the regular operation of the mines. When local restrictions are found insufficient, Congress should enact a law that will eliminate this evil till after the war, and any violation should be treated as severely as an offense against the operation of the draft law.

Aside from all else, one cannot but realize that it is unjust to the boys we are sending "over there" to spill their blood in the cause of freedom, while workers at home are permitted to idle away their time in the pursuit of pleasure or appetite. The boys have a right to expect every ounce of physical energy to be exerted at home in the cause for which they are fighting. This, and this alone, will shorten the war. LOYALTY.
Thomas, W. Va.

Letter No. 3—The letter of Thomas Hogarth, *Coal Age*, June 29, page 1208, regarding the present mining situation in the country, strikes a deep chord. I can bear testimony to what he says in regard to the time lost by miners visiting from town to town and place to place.

The foreign element is largely in the majority in our mining camps, and it is no exaggeration to say that they are making more money today for their labor than they did before the war began. But, as Mr. Hogarth remarked, they are spending it on themselves—for drinks and pleasure—instead of investing it in War-Savings Stamps and Liberty Loans that would help the Government. I certainly do not begrudge these men or any one for seeking their own pleasure after they have met the demands laid on them by the war.

Time and again I have looked out on the long line of cars waiting to be loaded only to feel downhearted and disgusted when observing the small number of men whose names appear on the time sheet as working. It is true, as Mr. Hogarth has intimated, that automobiling has interfered greatly with the work of the miner, by enabling him to take extensive trips into the country to see his friends or attend a festival or other celebration. The question may be asked, What is the cure for this condition?

GOVERNMENT OFFICER TO ROUND UP TRUANTS

The plan Mr. Hogarth suggests of appointing a Government inspector who would act as a truant officer seems feasible if the fine imposed on idlers were used for Red-Cross work, after paying for the services of the inspector, which would be a reasonable expense. However, this is not a time to apply harsh and severe measures without restraint. If I may be allowed the expression, it is a time to employ the iron hand and velvet glove.

It is only fair to say that the majority of our slackers, in the coal mines, do not realize the great sacrifices their brothers are making. Could they see the devastation in their homelands, where whole families have been wiped out and nothing remains of the old homesteads but ruins and shellholes, every day would find them at work.

I sometimes think if more pamphlets could be printed in the different languages of the mine workers, describing the devastation of their homelands, it would have a wholesome effect on them and take away their desire for idling away their time and seeking their own pleasure.

One more suggestion and I will close. We are working an eight-hour shift, but many of our miners spend but five or six hours in the mine. This means a great reduction in daily tonnage and is a situation hard to remedy. There has been some talk of working a nine-hour shift, but how would this effect anything when men fail to work the eight hours that mark the present working day?

My suggestion is to cut the shift to six hours and work two six-hour shifts in every 24 hours of the day. If this could be done, it would give us a 12-hour working day during the period of the war. The plan might entail a little extra cost in the supervision of the mines, but I should like to see the plan discussed and learn the opinion of *Coal Age* readers with reference to its feasibility.

R. W. LIGHTBURN.

Perryopolis, Penn.

Sealing Off Fire on Intake

Letter No. 2—The sealing off of a fire that has gained some headway on the intake air is a matter of considerable importance. The work should be promptly and thoroughly done.

In the case set forth by "Ancora," *Coal Age*, June 22, p. 1173, it does not appear to me that there is any great danger of explosion, since it is stated that the size of the heading is 6 x 10 ft. and an air current of 30,000 cu.ft. per min. is passing, while the quantity of gas generated is so small that it has not been necessary to use safety lamps, heretofore, in driving these headings.

The fire is said to be located in the timbers 30 or 40 yd. back from the face, and I will assume that the distance, from the last open crosscut to the face of the heading, is 50 ft. This will give an air space in each heading of $6 \times 10 \times 50 = 3000$ cubic feet.

Immediately upon being notified of the discovery of the fire, I would order hauled into the mine eight pieces of 8 x 8-in. square timber of suitable length; also, a sufficient amount of 1½- to 2-in. lumber and 40d. nails, and plenty of good clay for filling in the space between the board stoppings to be built in each heading.

Having proceeded at once to the place, I would tear away an opening in the stopping outside of the fire so as to short-circuit a portion of the air current, and reduce the amount of air passing over the fire.

As quickly as the material arrived, I would set four of the heavy timbers in each heading as close to the seat of the fire as the heat would permit and where there would be no danger of the timber being ignited by the heat. I would employ two crews so as to build a stopping on the two entries at the same time.

In answer to the two questions asked in regard to the condition of the air, let me say that if the intake stopping were built first it would have the effect of allowing much smoke to stand on the return airway; whereas if the return stopping were built first the air on the intake would be practically clear of smoke. In order to protect the men who are building the stopping, I would hang curtains just inby of each stopping, so as to cut off the heat from the fire. I shall be glad to learn the views of others on this matter.

Worley, Ky. OSCAR JONES.

Shortage of Mine Labor

Letter No. 3—Referring to the question of shortage of labor in the coal mines today, permit me to suggest one thing that appeals to me as an important consideration and deserving of more attention than it has yet received at the hands of coal-mining officials. Mention was made of this in an excellent article that appeared in *Coal Age*, June 8, p. 1058, entitled "War as a Supreme Test of Efficiency," by Edward N. Hurley. Attention is drawn to the great need of efficiency, as shown through the cost accounting in coal mining and other individual industries.

Today, the question of industrial efficiency should be uppermost in the minds of every class of men and to none does this apply with greater force than to officials in charge of coal-mining operations. There are efficiency experts in almost every other industry, and why should they not be employed in the operation of coal mines. No industry affords a greater field for activity, in this respect, than the mining, preparation and marketing of coal.

UNWARRANTED WASTE IN COAL MINES

Attention has been drawn many times, in *Coal Age*, to the great waste of material in the operation of mines. Those acquainted with underground conditions know well that there is often sufficient steel rails, timber and other necessary material to meet all requirements for some time to come when orders for such material are sent to the purchasing department.

The man whose duty it is to purchase the supplies makes no investigation to ascertain, were it possible, whether there is absolute need of the thing ordered. No checking system is employed to show how much material has been used since the last order was filled and how much should now be on hand. The mine management seldom realizes the wealth of material that is left to be covered up and lost in abandoned places.

Again, there may be plenty of locomotives already in the mine, for hauling the daily output to the shaft or slope bottom, but, owing to a lack of efficient distribution or the adoption of a proper system of haulage, the present equipment is inadequate. As a result, a requisition is sent to the office, calling for further outlay. The management finds, later, that the cost of supplies is high, and believing that it is the result of the increased cost of material, fails to realize what is the true cause of the losses shown by the profit-and-loss account. While making every effort to increase the capacity of the mine, mine officials seemingly forget, or at least fail to employ means that will secure the highest economy.

I have mentioned only one or two things that a good efficiency man would remedy if given supervision of the practical working of the mine and a record of supplies of material and labor. This is an important matter, especially at the present time when the Government is demanding an increased output of coal and greater economy in the use of material, in every industry. Efforts to increase the efficiency of coal operations will go far to offset the present shortage of labor in the mine.

Lochgelly, W. Va. ROBERT J. WOOD.

INQUIRIES OF GENERAL INTEREST

Blue Gem Coal in Tennessee

I want to ask if *Coal Age*, or any of its readers, can inform me if the thin seam of coal known as the "Blue Gem Seam" is being worked in Scott County, Tenn. We are working, in our mine, a thin vein of coal that averages 24 in. in thickness and is of good quality. The operation is known as the "Oneida Consolidation Coal Co." and the name of the mine is "Morning Glory." What I would like to know is if this seam is the true "Blue Gem" coal. INQUIRER.

Oneida, Tenn.

Probably some of the readers of *Coal Age* can give the information desired by this correspondent.

Handling Electric Detonators

On several occasions, I have heard of peculiar accidents that have occurred through the handling of electric detonators. These accidents may have resulted through carelessness or the neglect to take ordinary precautions. Inasmuch, however, as we are using these detonators every day in our mines and many of the men are none too careful, I want to ask if it is possible to explode a detonator otherwise than by the electric current.

In one instance that was reported to me some time since, the detonator was said to be exploded by pulling, twisting or scraping the lead wires, and I have wondered if that is possible. Other instances have been reported of the accidental explosion of detonators where I am led to believe that the explosion was due to the wires, in some way, coming in contact with a charged wire or an electrical conductor. STUDENT.

Peru, Ill.

This question was submitted to different manufacturers of electric detonators and electric fuses, with the result that it can be stated with certainty that when electric detonators are properly handled and not permitted to come in contact with live wires or to receive a static charge of electricity, there is practically no danger of an accidental explosion occurring.

A number of peculiar accidents have been reported, from time to time; but, in practically every case, the explosion was due to an electric discharge. It is stated that the construction of the detonating cap is such that any amount of twisting or scraping of the wires entering the cap could not cause the explosion of the fulminate, which is separated from the ends of the wires by fully an eighth of an inch.

In the manufacture of electric detonators, the safest practice has been to embed the ends of the wires or the platinum bridge in prepared guncotton, which is not sentitive to friction, but which is readily ignited by the incandescence of the platinum bridge of a low-tension detonator, or the electric spark of a high-tension detonator. The ignition of the guncotton causes the explosion of the fulminate in the cap.

In one instance reported, a man was dusting a bunch of electric detonators with a feather duster. As he held the bunch of exploders by the wires, in one hand, and applied the duster with the other, one of the caps exploded. In explanation of this occurrence, it was thought that the contact of the feather duster with the bunch of wires produced sufficient frictional electricity to fire one of the caps. This, of course, could happen only in a very dry atmosphere and where other conditions were likewise favorable.

In mining practice, it is well known that electric fuses and detonators are often handled in a very careless manner, and it may frequently happen that the lead wires are unconsciously brought in contact with a conductor that is sufficiently charged to cause the explosion of the cap. It requires a very slight current to explode an electric detonator, about $\frac{1}{2}$ volt and from 0.3 to 0.4 ampere being sufficient.

Few persons realize how readily a static charge can be produced in the human body. On a dry, cold day, a man with full physical development, by walking briskly over a Brussels carpet, can develop sufficient static electricity to ignite a gas jet by touching his finger to the metal tip of the burner.

While it is doubtful whether a sufficient static charge could be produced in a person, in a mine where the atmosphere is more or less damp, it is very possible that an electric exploder could be fired in this manner when all conditions are favorable. The question is an interesting one, and we hope to learn the opinions and experiences of others in this regard.

In reply to the question of whether an electric detonator can be exploded in any other way than by electricity, the answer is, Yes. All practical miners and many who are less practical and who have learned by sad experience, know that a detonating cap can be exploded by percussion. Men have lost their fingers through the explosion of a cap, the contents of which they were attempting to ascertain.

On the other hand, strange to say, an instance is recorded of a heavy box of dynamite falling on a detonating cap, which was crushed by the force of the blow, the shell being broken so that the fulminate was exposed and yet the cap did not explode. It needs no argument, however, to convince one that such an instance as this is quite the exception and forms no guide to the safe handling of such material.

Other facts, equally strange and inexplicable are detonating caps that have been mashed flat to a thickness not exceeding $\frac{1}{32}$ in. without explosion taking place. While these facts cannot be disputed they do not warrant a miner taking any chances in the handling of detonators. There is only one safe rule to follow and that is to avoid the unnecessary handling of exploders and keep them in a safe place out of harm's way.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—Suppose, in a main airway 8 x 10 ft., in section, the velocity of the air current is 1200 ft. per min. This volume is divided equally into two splits, whose respective areas are 6 x 8 ft. and 6 x 10 ft. What is the velocity in each split?

Ans.—The sectional area of the main airway is $8 \times 10 = 80$ sq.ft., and the volume of air in circulation is, therefore, $80 \times 1200 = 96{,}000$ cu.ft. per min. This volume being divided equally between the two splits, there is 48,000 cu.ft. of air passing in each split. The sectional area of the first split is $6 \times 8 = 48$ sq.ft., and the velocity in that split is, therefore, $48{,}000 \div 48 = 1000$ ft. per min. The sectional area of the second split is $6 \times 10 = 60$ sq.ft., and the velocity of the current is, therefore, $48{,}000 \div 60 = 800$ ft. per min.

Ques.—A mine car is 9 ft. long, 4½ ft. wide and 2 ft. high; how much coal will it hold, the dimensions to be inside?

Ans.—The cubic contents of this car is $9 \times 4\frac{1}{2} \times 2 = 81$ cu.ft. It is customary to estimate 40 cu.ft. of mine-run bituminous coal per short ton of 2000 lb. On this basis the car will hold $81 \div 40 =$ say 2 short tons when loaded without "topping."

Ques.—A mine is drained by natural means and the ditch carrying off the water is 12 in. wide and 12 in. deep. The drain is full of water, which has a velocity of 2 ft. per sec.; how many gallons of water are passing per minute?

Ans.—When the ditch is full of water, its wetted sectional area is $12 \times 12 = 144$ sq.in. A velocity of 2 ft. per sec. is $2 \times 60 = 120$ ft. per min. The quantity of water flowing in the ditch, under these conditions, is $(140 \times 120 \times 12) \div 231 =$ say 900 gal. per min.

Ques.—Where would you apply the water gage, and does it increase or decrease as the workings extend, all other conditions being the same?

Ans.—A water gage is used, in mine ventilation, for the purpose of computing the power on the air. It should therefore be placed on the fan drift in order that it shall take into account the entire resistance of the shaft and mine, which the ventilating fan must overcome. In this position of the water gage, its reading indicates the pressure established by the fan, which is above or below the atmospheric pressure, according as the fan is blowing air into or exhausting air from the mine.

It is the mine resistance that *causes* the pressure, which the fan *creates*. If the connection with the mine was broken, and the fan was operating in the open air, it would be able to create little or no pressure because of a lack of resistance, which must always cause the pressure. For this reason, as the mine workings are extended, the mine resistance is increased and the reading of the water gage correspondingly increased, other conditions remaining the same.

Ques.—In opening up a new mine, what would be the essential points to consider in making the opening and laying out the mine workings?

Ans.—It is important to locate the mine opening with due regard to both surface and underground conditions. As nearly as practicable, the opening should be located in the center of the property if this will afford a suitable building site, easy shipping facilities and favorable haulage and drainage in the mine. Regard must be had as to whether the mine should be opened by a shaft, slope or drift, in order to secure the most favorable conditions in its future operation, in respect to economy and safety.

Where the seam is inclined, it may be advisable to sink a shaft on the dip side of the property, in order that both coal and water shall gravitate toward the shaft. But, if the seam outcrops at a point offering good facilities for shipping it may be of advantage to open the mine with a slope and work out the coal in successive lifts, by rooms driven to the rise of the gangways or crossheadings. All of these considerations must be carefully studied in the location of a mine opening.

In laying out the workings underground, the direction of the main entries or haulage roads should be such as to give a suitable grade in favor of the loaded cars and afford good drainage. In like manner the direction of the rooms must be such as to permit of the safe and easy handling of the cars from the working face to the gangway or level.

Ques.—How many tons of coal in a room 200 ft. deep, 40 ft. wide and having an average height of 4 ft.?

Ans.—The cubic contents of this room is $200 \times 40 \times 4 = 32{,}000$ cu.ft. Taking the average weight of bituminous coal as 80 lb. per cu.ft., the weight of coal in the solid in this room is $32{,}000 \times 80 \div 2000 = 1280$ short tons.

Ques.—If a pressure of 2 lb. per sq.ft. produces a velocity of 200 ft. per min. what pressure would be required to produce a velocity of 400 ft. per min.?

Ans.—In mine ventilation, the unit of ventilating pressure varies as the square of the velocity of the air in circulation. To increase the velocity from 200 to 400 ft. per min., or to double the velocity in the airway will require, in this case, $4 \times 2 = 8$ lb. per sq.ft.

Ques.—Which gas is most dangerous to life, blackdamp (CO_2) or whitedamp (CO)? State why.

Ans.—Carbon monoxide (CO), commonly known, in the mine, as "whitedamp," is the more dangerous gas. It is extremely poisonous and gives no warning of its presence by the lamp flame; while carbon dioxide (CO_2) is not generally considered a poisonous gas and its presence, in the mine, is at once made known by the dimness or complete extinction of the miner's light. This gas is sometimes called "blackdamp" by the miners.

COAL AND COKE NEWS

What Happened in June

[The figures in brackets in the text refer to pages in the preceding volume when the figures exceed 100, and to pages in the present volume when the figures are less than 100. Reference to the items thus indexed will afford further information. "What Happened in May" appeared June 15 on page 1130.]

June 1—No. 5 mine of the Lehigh & Wilkes-Barre Coal Co. near Hazelton has button strike [1071, 1119]—Regulation enforcing the production of clean coal comes into effect [1068].

June 3—"Coal Week" (lasting till June 8) commences. All purchasers of coal are requested to place orders for all coal needed prior to Apr. 1, 1919 [973, 987] —Mt. Jessup colliery closed down by Fuel Administrator for shipment of dirty coal [1083].

June 4—Meeting of mine workers' delegates in the Huntingdon and Broad Top region vote in favor of returning to work pending arbitration [1071].

June 5—Operators' association formed in the new Elkhorn fields, Letcher County, Kentucky, at a meeting held at Whitesburg—Fuel Administrator issues estimates of bituminous coal likely to be needed from Apr. 1, 1918, to Apr. 1, 1919, at 634,594,000 short tons, or 79,866,000 tons more than produced in 1917. This will be an increase of 14.4 per cent. over last year's production [1116].

June 7—Production Bureau of United States Fuel Administration is inaugurated, with James B. Neale, anthracite advisor to the Fuel Administrator, as director [1162].

June 10—New freight rates under order of May 25 come into effect—United States Fuel Administrator states that the automobile factories will only be allowed 25 per cent. of the fuel necessary to maintain their former production [1162]—Strike at Bertha mine of Quality Cement Coal Co., in northern end of Fairmont region. Strike ends June 11 [1163].

June 11—Convicts mutiny at Banner mine, Pratt Consolidated Coal Co. Mutiny ends, June 13 [1164].

June 12—United States Fuel Administrator states that the curtailment of the fuel supplied to automobile factories will consider only the manufacture of pleasure cars and not the production of trucks for war purposes nor the output of other war necessities — German Government lodges complaint against lynching of the miner, R. P. Prager—Director of Railroads amends order of May 25 by which intrastate rates are placed at the same level as interstate rates, at the level to which they were increased in that same order. Intrastate rates are to be raised only 25 per cent. Minimum rate of $15 is made to apply only to line-haul shipments, and not to coal, coke or certain other bulky shipments. Prepayment of freight not required till Aug. 1 [1162]—Strike at Coal Brook colliery of the Hudson Coal Co., Carbondale, Penn. Strike ended June 20 [1164, 1202].

June 13—United States Fuel Administration gives the following list of precedences in coal distribution, all classes being preceded by the domestic user: (1) Railroad, (2) Army, Navy and Government departments, (3) state and county institutions, (4) public utilities, (5) retail dealers, (6) manufacturing plants approved by the War Industries Board for preferential coal, (7) less important industries [1161].

June 14—Fuel Administration of New Jersey removes 56 tons of coal from summer home of John F. Dryden, president of the Prudential Insurance Co. This is the first excessive stock of domestic coal reduced by Government action.

June 16—Announcement made by Secretary McAdoo that the next offering of Government bonds would be in October and for six billion of dollars.

June 17—"Clean-coal" Conference at Kansas City attended by operators, labor leaders and coal inspectors of Oklahoma, Kansas, Missouri and Iowa (23)—Cavein kills three men at Short Mountain colliery, a Susquehanna Collieries Co. operation near Lykens, Penn. [23].

June 19—J. P. O'Connor, doing business as the Penn Fuel Co., is deprived of his license as a coal distributor having sold high-volatile coal as bunker fuel.

June 20—Notice is served on the Tidewater Coal Exchange to dump coal promptly as received and not hold it for foreign bunkering so as to receive the higher price provided for such coal—Short Mountain colliery closes for two days while three men are buried [23, 24].

June 21—United States Fuel Administration declares that "Government prices" are maximum prices and that coal may be sold at lower prices to railroad and other customers at the pleasure of the operators.

June 22—New prices are set for anthracite received by rail or water on Lake Michigan and Lake Superior docks [1201].

June 24—United States Fuel Administrator approves prices set by local administration for coal produced in Texas [1201] —New prices are made for coke produced in Cumberland County, Tennessee, and at Ansted, W. Va. [1201].

June 25—James H. Hoover, of McClellandtown, Penn., is made to pay $2500 to American Red Cross for having violated the Fuel Administrator's orders in regard to the shipment of coke and having neglected to make reports as demanded by the Fuel Administration—James T. Lind, of Detroit, Mich., is made Director of the Bureau of Gas Plants in the Fuel Administration—Freight rates are increased in accord with General Order No. 28, dated May 25, 1918 [1020, 1021]—Dr. James Douglas, of Phelps-Dodge & Co., Inc., and of the Stag Canon Fuel Co., dies at Spuyten Duyvil, N. Y. [1217].

June 26—Henderson W. Knott appointed to take charge of engineers and inspectors investigating the power plants of the country and making recommendations relative to fuel economy—Coal operators of central Pennsylvania meet in Washington and condemn the giving of bonuses and like wage inducements. A board of nine persons will hear charges against operators whose rates of wage fail to conform to those set for them under the Washington Agreement [24].

June 27—Wagon Mine Owners' Association formed at Pittsburgh.

June 28—J. M. Roan is appointed field manager of the inspection section of the United States Fuel Administration [21]—Maximum price is set for cannel coal, the price to be $1 per ton in advance of the prices for bituminous coal in the district surrounding and 50c. a ton more being allowed where coal is shipped in a box-car [22].

June 29—New prices are set for coal produced in Hocking and Athens County, the southern half of Monroe township in Perry County, the Bailey Run or No. 7 seam, Guernsey Muskingum, Meigs and Jackson Counties [22]—Report of Federal Trade Commission condemning profiteering, the price of coal being quoted as an instance [21, 22].

Harrisburg, Penn.

A hearing was held in the Common Pleas Court of Pittsburgh recently on a petition of the Pittsburgh Coal Co. asking that an injunction be granted restraining the Pike Coal Co. from mining coal claimed to be the property of the petitioner and also from running an entry through an entry of the Pittsburgh Coal Co. The coal in question lies in a 112-acre tract of land in North Fayette township, where the Pittsburgh Coal Co. operates its Partridge mine. Each of the companies concerned has mining rights in the property and each claims that the other is mining coal that does not belong to it. The Court is asked to pass upon the question of how much of the coal in the property belongs to the Pittsburgh Coal Co., the deed to the Pike Coal Co. granting all the coal not previously granted to the petitioner. The Pike Coal Co. has found it necessary in order to reach all the coal owned by it, to drive an entry across an entry of the Pittsburgh Coal Co., and the latter asks that the Court restrain the former from crossing at grade. Judge Shafer directed that briefs be filed.

The acute labor shortage in the anthracite fields, due largely to the operations of the draft, is to be discussed at a conference of the local boards of the nine anthracite counties with state representatives at a meeting on Tuesday, July 16. The call for this meeting was issued on July 3 from state draft headquarters in this city. Early in the week the draft boards received from the district board at Scranton a circular stating that in future calls men holding certified miner's certificates, pump runners and others who cannot be replaced in the operation of mines would not be taken, and it is thought that the meeting to be held on the above date has been called to explain this action and discuss the advisability of further exemption.

The Board of Investigation appointed by the United States fuel administration to inquire into wasteful and uneconomic mines decided on July 1 to proceed at once against at least 25 bituminous coal mines in the central Pennsylvania district. Mines proved guilty of waste will be closed. Hearings will be granted in every case.

It is said that a good part of the car supply troubles in the central Pennsylvania district are due to the allotment system of the Pennsylvania R. R., which bases its rating of mines upon an estimate of working places instead of actual loading capacity. Under this system old mines are getting full-car supply, it is said, and in some cases are even getting more cars than they can load, while newer mines, with greater actual loading capacity, are restricted in supply and are hard pressed to hold their labor intact.

There has been an effort on the part of mine owners to get reratings from the Pennsylvania, but without effect. Now, it is understood, J. P. Cameron, the district distributor, is taking an interest and is endeavoring to get a rearrangement of car allotments.

Charleston, W. Va.

All the coal men of the state who have given the matter any thought assert that the most perplexing problem with which the industry is confronted is that of securing adequate man power to keep pace with the increasing car supply. Coal men conversant with the situation have no hesitancy in saying that the crux of the whole situation is the failure of miners to work for as long a period as they might and the inroads made upon the ranks of the miners by the draft. This is particularly true in the southern part of the state.

While the car supply this week for the Kanawha district is fair, the probabilities are that production will be curtailed owing to the fact that so many miners laid off for the holidays. Reports from Coal River in particular indicate that the mines there will be handicapped because so many of the miners went to Ohio or Kentucky over the Fourth.

The car supply in the New River district is all that can be desired, but the difficulty of getting men to work hampers production. In the opinion of one well known coal man identified with the New River field, it is no longer a car shortage which interferes with greater production. He is of the opinion that the government will have to more drastically enforce the "Work or Fight" order. The bonus system has had a tendency to disorganize the industry in sections where it has been attempted because it amounts, in the opinion of some operators, to nothing more nor less than stealing men, and the National Fuel Administration has advised against it. Hereafter it will be discouraged.

Conditions were somewhat improved in the Pocahontas and Tug River Districts during the last week in June, though labor shortage resulted in a loss of 40,508 tons. The car supply was a little better, however, there being about 42 more cars in the district. However, the increase in tonnage was not commensurate with the improvement in the car supply and in the labor supply, the total production for the districts mentioned being 439,672 tons. This repre-

sented a total of 7327 hours worked. From all causes, however, there was a tonnage loss during the week of 58,761 tons.

There was in the Fairmont field a fair run of cars during the week especially at the beginning and ending of the week. There was an over supply on Monday of last week but on Tuesday only a little over 1000 cars. By Saturday however, with 1573 cars available, only one mine of all those reporting was not in operation.

Louisville, Ky.

Kentucky's coal mines produced 27,355,727 net tons of coal during the year ended June 30, according to a report of Prof. C. J. Norwood, chief inspector of mines, at Lexington, Ky., and forwarded to Wiley B. Bryan, Fuel Administrator of Kentucky. The 19 coal counties in eastern Kentucky produced 17,479,194 net tons, and the ten counties in western Kentucky 9,876,533 net tons. Pike County, in the eastern Kentucky field, led the 29 counties in production with 3,838,358 tons. Missing reports and production from some wagon mines, which could not be obtained, would probably add 100,000 to 150,000 net tons to the total for the state. In order to take care of the 25 per cent. increase in coal freight rates, and increased cost of retail operations, the Jefferson County Fuel Administration has announced a general increase in all grades of coal, this increase being at the rate of 50c. a ton. Western Kentucky has gone to $5.90 a ton; Jellico, $7.10; Harlan, $6.75, and Hazard, $6.65. Western Kentucky mine-run is 25c. a ton lower than lump, and all other coals are 35c. a ton less for mine-run. For steam and industrial purposes the price is 50c. a ton less than to the domestic consumer. The dealer is allowed to charge $2.30 a ton for profit and operating expense on anthracite, $2.50 on coke, and $2.20 a ton on all other coals sold on this market.

Birmingham, Ala.

Coal miners throughout the Birmingham district, and from every section of Alabama, have given most patriotic response to the Government's appeal, and operations since July 1, including the Fourth of July, have been uninterrupted. The increased production is particularly noticeable at the Acton, Acmar and Margaret mines, where railroad freight cars in numbers were loaded July 4 and the day celebrated by full-time work on the part of the miners.

Efforts are now being made, particularly in the Birmingham mining district, to bring in labor for the mines, as the great complaint thus far has been that the unskilled worker is retarding rather than helping production. The Fuel Administration is lending every assistance to the mine operators and is using its influence to divert skilled workers to this district.

The Central Alabama Coal Co., with mines at Kimberly, in the northern part of Jefferson County, has begun mining of coal on the Black Creek seam, which lies under the Jefferson seam. The new seam coal will be brought out of the mines on the same slope, the haulage system being extended so as to reach the greater depth. It is intended to add to the force employed at Kimberly and increase production just as rapidly as possible.

All new mining propositions in the state are being worked to capacity, and the only trouble now being experienced is the inability to obtain sufficient skilled labor. The Railway Fuel Co.'s new mine at Parrish, the stripping proposition of the Eagle company in the lower section of Jefferson County, and the several other new mines recently opened up, are all doing exceptionally well.

The Woodward Iron Co. will soon be getting coal out of its mine west of Fairfield, where a camp is now being constructed. New mining projects of the Tennessee Coal, Iron and Railroad Co. in the Blue Creek region and elsewhere will also be pushed to the utmost during this month, it is officially stated.

Victoria, B. C.

Discussing the disallowance by the Dominion Government of the Provincial Statute giving the early settlers within the Esquimalt & Nanaimo Ry. belt the right to apply and, their claims on examination proving sound, to receive Provincial title to the coal rights in their lands, Hon. John Oliver, Premier of British Columbia, recently stated that he saw no reason why the Provincial Legislature, at its next session, should not be asked to reënact the legislation. This is taken to mean that the Province will insist on its power to give the settlers the privilege indicated. It also means that the present British Columbia Government is likely to maintain the principle of Provincial authority in the case in question. The issue is one of vital import not only to the settlers, whose coal lands are at stake, but as well to the Granby Consolidated Mining and Smelting Co., which holds Provincial title to valuable coal areas, and to the Canadian Collieries (D), Ltd., which claims title to all the non-alienated coal lands in the railway belt by virtue of the terms of the subsidy granted to the Esquimalt & Nanaimo Railway Co., in 1884.

PENNSYLVANIA

Bituminous

Connellsville—The Enterprise Coal and Coke Co. has bought a tract of land in Morgan Township, Greene County, Pennsylvania, for the record price of $700 an acre. The coal is the Pittsburgh seam, and it is said will be opened and operated immediately.

Connellsville—Announcement was made on July 6 that the coke workers on the Fourth of July had manufactured 60,000 tons of coke, a record for the Connellsville field. This is about 2000 tons above the daily average. The miners and coke drawers went to work as usual, the majority earning about $10 for the day. The output for the last week was 362,000 tons, indicating that the men at the different works are working every day.

Connellsville—An employee of the Fredericktown Coal and Coke Co., in the Fifth pool, Monongahela River, claims the coal-mining championship of the Connellsville region. John Slifko, a pick miner, dug and loaded 300 tons and 1000 lb. of coal in 12¾ working days, receiving $240.32 for his labor. Another employee, Joseph Cadman, earned $178.08 by loading 278 tons. At the same plant 45 miners averaged $137.42 each is earnings during the first half ow May.

Uniontown—Payment of $10,000 war risk insurance, taken out by John Meckleburg while he was in the National Army, is believed to have established a precedent for the administration of the war risk fund. Meckleburg met his death last March in an accident at the Continental No. 2 mine of the H. C. Frick Coke Co., two weeks after he had been honorably discharged from the army. While in the service he took out a $10,000 insurance act, dividing the payments between his parents.

Blairsville—The Pennsylvania Railroad Co. has completed a new concrete coal tower in its yards here. One of the greatest drawbacks for years, that of loading the locomotives with coal, will be eliminated and an engine can be coaled in a few minutes. The tower has a storage capacity of several hundred tons. Other improvements under way here are the enlargement of the roundhouse and extension of the yards to care for the increased coal traffic from the Indiana branch and West Penn branch.

Uniontown—The trustees of J. V. Thompson have sold to the Stern Coal Co., a local corporation, the coal underlying the 75-acre tract of land adjoining the County Home west of the town and already opened through the Snyder mine. The basis of the transfer is a royalty payment of $5800 per acre as the coal is mined. This tops by $800 a similar contract made last winter for the 100-acre County Home tract and is the high-water mark for Pittsburgh seam coal deals. The coal taken from this acreage will be sold in Uniontown for domestic consumption.

Anthracite

Pottsville—The Sherman Coal Co., operating on Sharp Mountain, has made application to the City Council for permission to extend its works to include a portion of Cressona Road. It is planned to increase the capacity.

Hazleton—The old workings at Hollywood, near here, have been reopened by the owners, Pardee Bros. & Co., and will be worked by electrical equipment.

The Cranberry Creek Coal Co., operator of the Cranberry mines near here, is receiving bids on a stripping proposition which will remove the overburden from a 22-ft. seam recently proved and plotted, and which adjoins its No. 4 workings.

St. Clair—The Pine Forest colliery, the newly opened operation of the Philadelphia & Reading Coal and Iron Co., broke all records on July 5 for a new operation when 1270 tons of coal were shipped. Officials say the production will be increased until a maximum of 1500 tons daily is reached. There is a spirited rivalry between this operation and the Ravensdale colliery, also a new Reading operation, and shipments from both are constantly increasing.

Nanticoke—An explosion of gas in the Loomis colliery of the Delaware, Lackawanna & Western Railroad Co., on July 6, resulted in four mine workers being badly burned, necessitating their removal to Nanticoke State Hospital. Their condition is serious, it is reported. Soon after the men were removed from the colliery hospital, the superintendent and other officials descended the shaft and braved the danger of afterdamp in conducting an investigation.

Port Blanchard—Showing that they are alive to the country's need for a maximum coal tonnage, the workers employed at the No. 14 colliery of the Pennsylvania Coal Co. last week established a remarkably high average production. One day 2600 cars were sent through the breaker. To bring about such a big production the men worked longer than the limit designated by union rules; in fact, in some cases some of the men worked double shifts, with none of the workers filing the least objection to the requests of the officials.

Scranton—The Scranton Coal Co., which operates the Pine Brook colliery, is about to open the New County seam. This seam contains a large amount of fine coal and will greatly extend the life of the colliery. The New County bed is about 100 ft. below the surface and is overlaid by the Fourteen-foot seam, which was worked out some years ago. For some years there was doubt about the practicability of mining the seam, but boreholes made by the company prove the seam averages from 5 to 8 ft. thick. It will be mined with machines.

Forty Fort—The growing peril of mine caves in the Wyoming Valley was pointed out by attorneys for the Temple Coal Co. in its appeal from the assessment placed by the county on the coal properties of the company on the west side of the Susquehanna River. In 1916 the board of county assessors increased the amount of coal as minable and removable from 62 to 70 per cent. The coal company appealed and holds that it is impossible to remove that percentage owing to the river wash, sand and gravel, and that any increase above 62 per cent. would endanger the property through extensive settlement and water from the river.

Mauch Chunk—Harry A. Butler and N. D. Courtright, the lessees of the Switchback R. R., have organized the Mount Pisgah Coal Co. The mine is on the top of Mount Pisgah, along the Switchback R. R., only a short distance from the place where the first anthracite coal mine in the world was opened shortly after the discovery of anthracite coal in Summit Hill in 1794 by Philip Ginder, the hunter. The coal from this mine was then brought to Mauch Chunk over the Switchback and run down the river by means of chutes and loaded into boats. The coal mined on Mount Pisgah is of the very best quality, and the new firm is making arrangements to carry on mining of anthracite on an extensive scale.

WEST VIRGINIA

Montgomery—A number of new houses for miners are being built by the New Export Coal Co. at its Perryville mine on Campbell's Creek in the Kanawha field.

Philippi—Colonel Albert Thompson, of Philadelphia, who has been operating mines at Meriden for a number of years, has disposed of his interests there to the Franklin Coal and Coke Co., of Philadelphia, the price paid for the Thompson interests being $800,000.

Kingwood—Plans for the operation on a large scale of coal mines in Preston County are being made by the P. N. and R. W. Coal Co., which recently secured a charter from the Secretary of State for a $50,000 company incorporated by I. R. Nicodemus, of Fairmont; J. W. Wise, T. M. Rotruck, of Williamsport, W. Va.; C. W. Powers and Annie Powers, of Piedmont.

Fairmont—The tipple and other buildings at the Montana mine of the Consolidation Coal Co. burned down last Tuesday were restored before the end of the week and the mine was in commission again Friday. Working day and night shifts, C. H. Tarleton, manager of the West Virginia division, had the repairs made and the mine in operation within 86 hours after the fire.

Charleston—A large tipple is being built by the Smith Mining and Fuel Co. at Plus, W. Va., preparatory to opening a mine in the Coalburg seam.

Twenty-five hundred acres of coal land in Boone County, leased on a minimum royalty, will be developed if the railroad and fuel administrations give their sanc-

tion. With a view to such development, Quinn Morton, a prominent Kanawha Valley coal operator, Walter S. Wood, Staige Davis, L. H. Bobbitt and Mary E. Morris, all of Charleston, have formed the Hopkins Fork Coal Co., to which a charter has been granted, the company having an authorized capital of $99,000.

VIRGINIA

Graham—The Bradshaw Coal Co. is planning to increase the capacity of its works. Considerable new equipment for operation will be installed.

Roanoke—The Ragland Coal Co. is planning for the installation of new electric equipment at its works. The installation will include generator, engine and auxiliary apparatus.

KENTUCKY

Star Hill—The Star Hill Coal Co., recently incorporated, is planning for the development of extensive coal properties in this vicinity. The company's land includes a total of over 100 acres, and complete mining equipment will be installed for operation. J. B. Rogers is vice president.

Wallins Creek—The Wallins Creek Colliery Co. has recently taken over the holdings of the Wallins Creek Coal Co., having a capacity of about 700 tons daily. Plans are now under consideration for extensive improvements and the installation of considerable equipment to increase the present output.

Mayking—Thomas G. Langford, Memphis, Tenn., and associates, are considering plans for the construction of a new two-mile branch railroad extending to an extensive tract of coal property recently leased on Pine Creek. It is planned to commence active operations for development at an early date.

Paducah—The Columbia-Panama Coal Co. has commenced surveys for the construction of a railroad line to reach its properties in the Goose Rock district. At this location the company has about 2000 acres of land and will install a complete equipment of mining machinery to develop the property. W. A. Calhoun is chief engineer.

Sebree—The New Sebree Mining Co., capital $100,000, is being organized to take over the operations of the Sebree Coal Co., one of the older operating companies of the district. The incorporators are F. T. Patterson, J. D. Smith and J. M. Anderson, all of Birmingham, Ala. Mr. Patterson will be president of the company, Mr. Smith, vice-president, and Mr. Anderson, secretary-treasurer.

OHIO

Jacksonville—The Ohio Mining Co. has opened a new mine, located on the Toledo & Ohio Central R. R., which will have a capacity of about 150 tons daily. The mine works in the No. 6 seam, which is 6 ft. thick. A modern tipple equipped with screens has been installed.

Bannock—Elsworth E. Brown has disposed of his 400-acre farm to the Union Coal Stripping Co., of Cleveland, Ohio. The farm is situated near Lafferty, a few miles from Bannock, and is part of the extensive coal belt extending from Flushing to a point in the Buttermilk Valley.

ILLINOIS

Springfield—Automatic coal feeders are being installed at the city pumping plant which are expected to reduce the consumption 10 per cent.

Collinsville—Fire of unexplained origin destroyed the plant of the Arctic Ice & Fuel Co. here on July 4, causing a loss of $10,000. In addition to the building a large motor truck and five mules were destroyed.

Athens—In response to farmers' appeals, miners have been doing a day's work in the harvest fields after doing a day's work in the mines. On coming out of the mines they eat a hasty supper and then go into the fields and shock wheat until dark. As it does not get dark until nearly 9 o'clock, their day in the fields is almost as long as their day in the mines.

Harrisburg—Defective helmets are said to have caused the death of William Taylor, Loren Whitler and Robert Kennedy, members of the mine rescue crew of the O'Gara mine No. 1, who succumbed when they entered a room June 29 which had been sealed for four weeks on account of fire. It is claimed that this could not have happened if the helmets had been all right.

Spring Valley—Every miner employed in the mines of the Spring Valley Coal Co. at Spring Valley and Dalzall, is a member of the American Red Cross and of the War Relief Association. They are giving at the rate of 50c. a man during the period of the war. The motion to pay this amount was put through in three locals without debate, without a protest and without a dissenting vote. Last week the Spring Valley Coal Co. sent in its check for $500, as a lump-sum contribution for the year for that company.

Ziegler—The Ziegler Coal Co., which has completed the purchase of 2000 more acres of coal lands in Franklin County, Illinois, now has 9000 acres of the finest coal lands in the county. Best of all, these lands lie in one body. The Bell & Zoller Mining Co. is now operating the large 5000 ton-a-day mine on these holdings, and is at present sinking a new mine south of Ziegler which will give them a daily capacity of 6000 tons. The sum of $1,500,000 is being expended on the new mine, which will be one of the finest in the state. There are now 1000 men employed at Mine No. 7, and it will require 1400 men at the new mine. Most of the men earn from $5 to $9 per day. There are now 116 new residences in Ziegler all built along modern lines, and 200 more houses will be constructed by Jan. 1, 1919. Ziegler is now an incorporated town and has been since Aug. 17, 1917. Prior to that date it was only a mining camp owned by one man.

ALABAMA

Bessemer—W. C. and R. E. Sellers, of Birmingham, who recently sub-leased from J. J. Shannon and associates Bamford mine, about 12 miles from Bessemer, will shortly begin the production of coal from this opening, which has been idle for a number of years. The old spur to the Southern Ry. has been reconstructed, and structures and mining equipment have been provided for resumption of operation.

Birmingham—The Southern Cotton Oil Co. has purchased the properties of the Summit Coal Co., located near Dora, Walker County, and consisting of about 900 acres of Black Creek coal, the consideration as reported being $45,000. It is announced that improvements will be made, including the erection of a new washer and installation of electrical haulage. The purchasers expect to provide their various plants with fuel from the properties purchased, on which there is now an opening producing about 125 tons daily.

The Republic Iron and Steel Co. is making good progress in the construction of its new washeries and screening plants at Sayreton, Jefferson County, and Palos, Walker County, the only deterring features being the scarcity of labor and the difficulty and delay experienced in securing deliveries on equipment.

OKLAHOMA

Henryetta—The Fretwell Coal Co., which recently filed notice of an increase in its capitalization from $10,000 to $50,000, has commenced active operations on the development of a tract of coal lands comprising 490 acres. It is planned to have a daily capacity of 500 tons.

Foreign News

Winnipeg, Man.—At a joint meeting of the Board of Control and Civic Coal Committee on June 29, it was stated that of the 150,000 tons of soft coal required as a minimum for the winter supply only 25,000 tons had already been secured. Mayor Davidson stated that it was no longer a question of price, but one of getting the coal at any cost or freezing next winter. It was decided to send two members of the Civic Coal Committee to Alberta to investigate coal conditions there.

Personals

George Wall has been made superintendent of the Christian Colliery Co., at Mahan, W. Va. Mr. Wall was formerly superintendent of the Coal Valley Coal Company.

F. E. Herriman, coal traffic manager of the New York Central, who on June 19 was appointed vice president of the Clearfield Bituminous Coal Corporation, on July 8 was elected president of the corporation.

M. W. Price, who was safety engineer with the Lehigh Valley Coal Co. for a long period, and more recently with Weston Dodson & Co., in their southern mines, has taken a similar position with the G. B. Markle Co. at Jeddo, Pennsylvania.

I. J. Barry, of Indiana, Penn., has resigned his position as superintendent of the Indiana County Street Railways Co. to become general manager of the Bardes Six-Four Coal Co. in which he is interested. The Bardes company is opening two new mines near Homer City, Pennsylvania.

Josiah Bachman, secretary and treasurer of the Weston Dodson & Co., Widener Building, Philadelphia, Penn., and connected with the company for the past forty years, has resigned from active service, effective July 1. George C. Radford, formerly assistant treasurer, has been elected treasurer succeeding Mr. Bachman, and C. B. Jacoby has been elected assistant treasurer.

Obituary

Dr. John S. Wentz died on July 1 at his home in West Philadelphia, Penn., aged 81. He was prominently identified with anthracite mining for many years, representing the Wentz and Leisenring interests in the management of the Upper Lehigh Coal Co., Mary D. Coal Co., Midvalley Coal Co. and J. S. Wentz & Co., as president. Dr. Wentz and family associates acquired some 100,000 or more acres of bituminous coal lands in southwestern Virginia, organizing under the name of Virginia Coal and Iron Co. A part of these holdings was operated by the Wentz interest as the Stonega Coal and Coke Co. During the last ten years his son, Daniel B. Wentz, now in the service in France, was the practical head of these coal companies.

Trade Catalogs

Cambria Wire and Nails. Cambria Steel Co., Philadelphia, Penn. Pp. 47; 4¼ x 7¼ in.; illustrated. Latest edition of the Cambria company's wire and nail catalog.

C-H Battery Charging Equipment. Cutler Hammer Manufacturing Co., Milwaukee, Wis. Pp. 4; 8½ x 11 in.; illustrated. Describes charging equipment for electric vehicles and industrial trucks.

List of Steel and Other Products. Midvale Steel and Ordnance Co., Cambria Steel Co., Philadelphia, Penn. Pp. 55; 4¼ x 7¼ in.; Unillustrated. An index of the more important products manufactured by the company.

Circular Letter No. 123. Ironton Engine Co., Ironton, Ohio. Pp. 4; 8½ x 11 in.; illustrated. Describes three Ironton locomotives "that will gather coal under all conditions." Specifications are given for the three machines.

Twenty-eight Years of Steel Pipe Progress. National Tube Co., Pittsburgh, Penn., Pp. 4; 8½ x 11 in.; illustrated. Tells graphically the story of years of progress in the manufacture of the National Tube Co.'s product.

Sullivan Ironclad Coal Cutters. Sullivan Machinery Co., Chicago, Ill. Bulletin No. 73. Pp. 48; 6 x 9 in; illustrated. Describes this concern's cutter for room-and-pillar and longwall mining. Ironclads of both types are manufactured for electric drive, either direct or alternating current, or for compressed-air drive, with "Turbinair" motors.

C-H 9116 Starting Switch for Squirrel Cage Motors. Cutler-Hammer Manufacturing Co., Milwaukee, Wis., Pp. 4; 8½ x 11 in.; illustrated. Two-color pamphlet showing four typical installations of this type of switch. An interior view shows construction and arrangement of starting and running contacts, fuses, etc. Manner in which motor is connected to the line ahead of the fuses, without opening circuit to the motor in the transition, is clearly indicated.

Abstracts of Current Decisions on Mines and Mining. Reported from September to December, 1917. By J. W. Thompson. Department of the Interior, Bureau of Mines. Bulletin 164, Law Serial 14. Unillustrated 146 pp., 6 x 9 inches.

Industrial News

Ashland, Ky.—The Green Rock Coal Co. has filed notice of an increase in its capitalization from $5000 to $25,000 to provide for expansion.

Richmond, Va.—The Sabine Collieries Corporation has filed notice of an increase in its capitalization from $500,000 to $600,000, to provide for business extensions.

Charleston, W. Va.—The Harry B. Coal and Coke Co. has recently filed notice of an increase in its capital from $100,000 to $300,000, to provide for business extensions.

Middlesboro, Ky.—The Riverside Coal Mining Co. has filed notice of an increase in its capitalization from $25,000 to $50,000, to provide for extensions, improvements, etc.

Chicago, Ill.—The Michigan Central Railroad Co. has taken bids for the construction of a new coaling station to have a capacity of 300 tons, to be located at North Toledo, Ohio.

Chelsea, Mass.—Ribock & Sevinor, 72 Walnut St., have awarded a contract for the construction of a new 1-story coal elevator plant at their works, about 30 x 60 ft., to cost $10,000.

Utica, N. Y.—The Bossert Co., 1019 Hickory St., has had plans prepared for the construction of a new coal pocket at its plant to cost about $10,000. James R. Jones is general manager.

Juneau, Alaska—Preliminary work has been started by the Alaskan Engineering Commission in the construction of a spur track into the Baxter coal mines on Moose Creek, from the Chickaloon branch.

Mannington, Ky.—The Memphis Coal Co. is considering plans for the immediate erection of a new steel tipple. The company is also planning to increase the capacity by the development of an additional mine.

Whitesburg, Ky.—The Long Ford Coal Co., recently organized, has leased an extensive tract of coal lands near Long Fork, and is planning for the immediate installation of the necessary machinery for development.

Baltimore, Md.—The Penn Smokeless Coal Co., Pittsburgh, Penn., has recently acquired property at Lawrence and Decatur Sts., Baltimore, and is planning for the construction of a new coal tipple, storage bins and offices.

Whitesburg, Ky.—The Elkhorn Superior Block Coal Co. has filed notice of an increase in its capitalization from $35,000, to $100,000, to provide for the installation of new equipment at its plant, including electrical machinery.

Birmingham, Ala.—The Turkey Creek Land and Coal Co. has been incorporated with a capital of $10,000 to engage in a general coal-mining business. Charles E. Francis, A. W. Stearns and George Maesta are the incorporators.

Oakdale, Penn.—The Carnegie Coal Co. is rebuilding its tipples at Armide and Oakdale mines, having contracted with the Roberts & Schaefer Co., engineers and contractors, Chicago, for Marcus picking table screens at each mine.

Akron, Ohio—The Canton-Akron Coal Co. has been incorporated with a capital of $50,000 to mine and sell coal. The incorporators are James R. McAllister, Charles Blain, J. E. McAllister, Leo A. McAllister and John E. Morgret.

Hornell, N. Y.—The Erie Railroad Co., Jersey City, N. J., has awarded a contract to Fairbanks, Morse & Co., South Wabash Ave., Chicago, Ill., for the construction of new coal pockets with equipment, at Hornell. The work will cost about $150,000.

Charleston, W. Va.—Having leased a tract of coal land on Campbell's Creek in the Kanawha field, J. S. Cheney, formerly of the Stonegap Colliery Co. at Glamorgan, Va., and James Raisbeck, together with their associates, will develop the leased property.

Seattle, Wash.—The price of Wyoming coal has increased 35c. a ton in California, the raise being granted by the fuel administration to meet a higher price at the mines. Increases of 50c. per ton on California coal and 75c. per ton on coke to cover added cost of transportation were authorized July 1.

Cincinnati, Ohio—The Reliance Coal and Coke Co., 897 Union Trust Building, is pushing arrangements for installing modern coal-handling equipment in the old Marmet Coal Co. yards, recently acquired, and is purchasing coal-elevating and handling machinery as well as trackage and equipment for yard purposes.

Louisville, Ky.—Philip M. Riefkin, of Washington, D. C., and Alexander Henry, Jr., of Wilmington, Del., have contracted with 41 operators in the western Kentucky field for 7000 tons of coal per day to be delivered to the Hadley's Bend plant of the DuPont Powder Co., near Nashville. The contract is dated Apr. 1, 1918, and runs for a period of one year.

Henry Ellen, Ala.—The Donaldson-Stobert Coal Co., recently organized, is planning for the immediate development of approximately 280 acres of coal lands to have a capacity of from 300 to 400 tons daily. J. W. Donaldson is president; Thomas Berry, vice president; and T. Stobert, secretary and treasurer. Offices of the company are in the Brown-Marx Building, Birmingham.

Warfield, Ky.—The Easton Coal Co. has leased extensive properties on Buck Creek, including several mines having a capacity of about eight carloads per day. It is said the company is planning for extensive improvements and the installation of the necessary machinery to provide a daily capacity of about 35 carloads. The work is estimated to cost approximately $300,000. D. W. Farquharson, Welch, W. Va., is president.

Clendenin, W. Va.—The Elk Gas Coal Co., recently incorporated with a capital of $50,000, has perfected its organization and is planning for immediate work on the development of 400 acres of coal lands, to have a capacity of about 100 tons daily for initial operations. Work will be commenced at once on the installation of the necessary machinery, including hoisting apparatus, electric motors, etc. L. V. Koontz is president.

Columbus, Ohio—The Ohio Board of Administration has started to purchase approximately 500,000 tons of coal for the various state institutions under its care. This is the earliest that the board has started its purchasing, but a valuable lesson was learned last winter. The board has also purchased four large motor trucks to transport coal to the institutions whenever possible. Additional storage space has been provided at most of the institutions.

St. Louis, Mo.—The East St. Louis Retail Coal Dealers' Association, of which John Thomas is president and J. T. Maule, secretary, has filed with Fuel Administrator Baxter a petition for permission to charge higher prices for coal. They state that at the present prices, $4.50 for Standard, $4.75 for Mt. Olive and $5.25 for Carterville, the gross margin is $1.20 per ton, which they say is much below the margin allowed in St. Louis and St. Louis County, and in various Illinois cities.

Columbus, Ohio—Joseph H. Frantz, the newly appointed Ohio Fuel Administrator, has taken up his duties, and his first announcement was the retention of C. F. Mayer as executive secretary. Mr. Mayer has been operating the office since the resignation of H. H. Johnson, the former administrator. The administration has started a new survey of the amount of coal in the cellars and bins of domestic users, and a full report will be forthcoming in the near future.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the appointment of L. C. Sprague as its special representative in connection with the sale of pneumatic tools to railroads. Mr. Sprague was formerly connected with the tool company, but more recently has been connected with the railroad department of the H. W. Johns-Manville Co., New York City. His long connection and association with the railroads of this country especially fits him for the work which has been assigned to him.

Toledo, Ohio—Considerable activity prevailed at the docks during the past week, despite the intervention of the holiday. This is shown by the records of loadings at the Hocking Valley and Toledo & Ohio Central docks. The Hocking Valley docks loaded 157,427 tons for the week ending July 6, as compared with 140,450 tons the previous week, making a total of 1,334,804 tons since the opening of navigation. The Toledo & Ohio Central loaded 61,000 tons, as compared with 63,735 for the previous week, making a total of 700,000 tons since the opening of the lake season

New York, N. Y.—The Quigley Furnace Specialties Co., Inc., has opened a branch office in Pittsburgh at 427 Oliver Building, to handle the sale of powdered coal equipment, and Hytempite furnace cement. The powdered-coal engineering department will be in charge of L. V. Marso, formerly maintenance engineer of the A. M. Byers Co. plant at Girard, Ohio, and the specialties department will be taken care of by J. L. Cummings, Jr., formerly connected with the sales department of the company at New York.

Columbus, Ohio—J. M. Roan, who has been appointed field manager for the inspection division of the Federal Fuel Administration, effective July 1, is now organizing his office force. He will have his headquarters in Columbus and his jurisdiction will be country wide, extending in all mining districts. He has authority to name deputy inspectors to see that coal is prepared and cleaned properly. Just how many inspectors he will name has not been determined as yet. He also has authority to make suggestions and orders if necessary, to both operators and miners, in carrying out his duties.

Buffalo, N. Y.—The Consumers' Collieries Corporation has been organized here, with W. H. Hayden, president and treasurer; Willis M. Spaulding, secretary, and Charles B. Kinne, general sales manager. The company owns the Good Hope mine near Reynoldsville, Penn., which has been operated in a small way for the past year. It is now being put into condition to produce 300 tons daily in about 60 days. A second opening was planned, which is expected to bring production up to 1000 tons daily. The principal office is in Buffalo.

Louisville, Ky.—The Gordon & Miller Coal and Coke Co., composed of Ross E. Gordon, J. S. Miller and Boyce Watkins, is planning to file charter papers with a capital of $200,000 within a few days. The company has arranged to take over the improved mine of the Lynndale-Jellico Coal Co., at Lynndale, Ky., near Barbourville, on the main line of the Knoxville division of the Louisville & Nashville. The company has a tipple and trackage into its plant. It is planned to put in additional machinery, a power plant and other equipment to increase the capacity to about 20 cars a day.

East Pittsburgh, Penn.—The Westinghouse Electric and Manufacturing Co. announces a change in representation in its Western District, with headquarters at Indianapolis, Ind. Prescott C. Ritchie has been appointed district representative to succeed H. S. Johnson, whose resignation becomes effective June 30. Mr. Ritchie has had a considerable amount of experience in the automobile industry, having been in charge of headquarters' inquiry work, for the Western District, in the main offices of the company for some years past, and prior to that time he was connected with the Thomas B. Jeffrey Co. at Kenosha, Wisconsin.

Columbus, Ohio—The Buckeye Coal and Railway Company, of Columbus, has closed a number of leases on acreage in Athens and Hocking Counties which means the opening of quite a number of new mines in the Hocking Valley district. In all cases the leasing company retains the sale of the coal. Among the leases are:

Snow Fork Coal Co., 200 acres in Hocking County located near Murray on the Hocking Valley Ry. to be developed at once and to produce about 50,000 tons yearly.

Riddle Coal Co., of Murray, 50 acres in Ward township, Hocking County, No. 6 seam, entry being driven and spur under construction.

Star Coal Co., not incorporated, De. E. M. Cox, manager, 100 acres in Trimble township, Athens County, partly worked-over land. A new plant is under construction to mine No. 6 seam.

The Oakland Fuel Co., of Sand Run, has leased 153 acres of No. 6 seam in Ward Township, Athens County, which has been worked over. A new plant is being constructed.

The North Hocking Coal Co. has leased 320 acres of No. 7 coal near Murray. The tract will be developed immediately.

MARKET DEPARTMENT

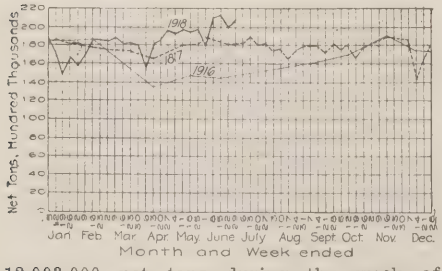
Weekly Review

Large Production of Bituminous Continues—Conservation and Curtailment the Order of the Day—Anthracite Industry Doing Its Utmost to Maintain Output—Distribution Receiving Attention—Markets Active

GRATIFICATION at the continued large production of bituminous coal is tempered by several circumstances which would tend to indicate that Fuel Administration officials, though optimistic, are in nowise prone to underestimate the probabilities of a fuel shortage next winter. "Lightless nights" are again to be resorted to, as much for their psychological effect on the coal-consuming public as for the coal saving that will result; non-war industries are discovering that the plan to curtail their fuel supply is no empty bubble—witness the 50 per cent. reduction to brewers of alcoholic and non-alcoholic cereal beverages; and now the Hoover idea has been extended to the domestic consumer, who will receive only enough coal to keep his indoor thermometer hovering around 68 degrees.

The railroads at this time of the year operate at the peak load of their efficiency. Weather conditions are propitious to the rapid movement of cars; crops have not yet been harvested and therefore do not congest transportation facilities; the unified control of the railroads makes for general betterment in service—all of which was reflected in the output of 12,458,000 net tons of soft coal during the week ended June 29.

The status of the anthracite situation has undergone no change. For the week ended June 29, shipments of hard coal amounted to 41,641 cars, 471 cars in excess of forwardings for the preceding week, but still less than the best performance made in the recent past. So insistent is the demand for anthracite that all the inventive genius in the hard-coal industry is engaged in the task of devising new means of producing more coal. Modern devices are being installed; old abandoned mines are being opened up and worked anew; more electric power is being used to supplant rapidly diminishing man power; miners are being asked to do their best in the interest of the Nation. Suffering from a shortage of labor, and with no relief in sight, the anthracite industry is doing its utmost to maintain a maximum output close to 275,000 tons of hard coal daily.



Recognizing the importance of stimulating and speeding up the production of both anthracite and bituminous, the Fuel Administration at the same time realizes that unless there is a proper distribution of the coal after it leaves the mines many injustices and hardships will be worked. To that end each retailer in the United States has been ordered to report the amount of his coal receipts, the quantity he delivers and the stock he has on hand. The plan has been in operation in New England for some time, and now it is to be extended throughout the country. For failure to comply with the regulations in this regard, 750 retailers in New England recently were given five days in which to file their reports or have their supply shut off. So it can readily be appreciated that this order has teeth in it.

Both the wholesale and retail domestic markets are active, and much coal is being distributed and stored. However, retailers are not receiving anything like their requirements, and householders are thus being greatly delayed in laying in their winter supply. New York and New England seem to be as needy of coal as ever, and the trade is wondering if the movement of 900 cars a day to New England will be ordered to continue throughout July.

With the steady shipment of coal to the Lakes from the West Virginia section which was set aside exclusively for that purpose, the movement of coal to the lake ports is assuming larger proportions. It appears to be more and more evident that unless something unforeseen occurs the Middle West and the Northwest will be well taken care of by the time cold weather sets in.

COAL PRODUCTION

Production of bituminous coal during the week ended June 29 not only exceeded the production of the week of June 22 by 455,000 net tons, or 3.8 per cent., but resulted in the second highest weekly production in history. The output (including lignite and coal made into coke) is estimated at 12,458,000 net tons as against

12,003,000 net tons during the week of June 22 and 11,583,000 net tons during the current week of 1917. The average production per working day is estimated at 2,076,000 net tons, an increase over the preceding week of 75,000 net tons or 3.8 per cent. and over the same week of 1917 of 145,000 net tons or 7.5 per cent.

Increased shipments during the week ended June 29 were reported from all districts with the exception of central Pennsylvania and Alabama. The decrease from Pennsylvania amounted to 1.8 per cent. and from Alabama 2.4 per cent. Material increases in shipments from the district including northeast Kentucky, high-volatile fields of West Virginia and the smokeless fields of West Virginia amounted to 13.0 per cent., from southwest Virginia 11.8 per cent., from Ohio 10 per cent. and from the Fairmont district 5.7 per cent.

Anthracite shipments increased 471 cars during the week ended June 29, the total movement amounting to 41,641 carloads.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended June 8	June 15	June 22	June 29
Bituminous shipments, 123 roads	219,839	222,892	212,849*	221,801†
Anthracite shipments, 9 roads	40,754	41,960	41,170	41,641

* Revised from last report. † Subject to revision.

Material decreases occurred during the week of June 22 in Illinois, Indiana, southern Ohio, Westmoreland, Fairmont, southwest Virginia and in Kansas and Missouri. Insufficient car supply caused production to decline in Indiana, southern Ohio and Fairmont, while in Illinois the declined production is attributed to both car and labor shortages, in Westmoreland and Kansas and Missouri mainly to labor shortage and in southwest Virginia to mine disability and other causes. Increased production in the high-volatile fields of southern West Virginia and in the Hazard and northeastern Kentucky fields is entirely attributed to better transportation conditions. The increase in northern and central Ohio and in Oklahoma and Arkansas is due to improvement in car and labor conditions. During the week there was a market in Illinois for all coal mined while in Kansas and Missouri and in the far west states market conditions improved considerably.

Beehive Coke—The production of beehive coke in the United States during the week ended June 29 is estimated at 604,000 net tons, a decrease compared with the week preceding of 6000 net tons or slightly less than 1 per cent. The average production per working day is estimated at 101,000 net tons as compared with 102,000 net tons during the week ended June 22. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production for the week ended June 29 at 401,114 net tons, the plants being operated at 77.4 per cent. of their present capacity in comparison with 75.5 per cent. during the week of June 22.

Byproduct Coke—The byproduct plants of the country were operated at over 90 per cent. of their full-time capacity during the week ended June 29. The operators reporting produced 496,396 net tons, their plants being operated at 90.5 per cent. as against 89.4 per cent. during the week of June 22. Losses due to labor shortage and repairs to plants decreased during the week, causing the improvement. Material increases in production occurred in Alabama and Pennsylvania. The operators in the former state attribute the improvement to a hundred per cent. coal supply and repaired plants, and the latter state to better labor conditions.

Atlantic Seaboard

BOSTON

A gradual increase in all-rail receipts, but volume is still inadequate to build up necessary stocks. Clear now that 4500 cars weekly from central Pennsylvania for New England cannot be relied upon. Several instances at tidewater where cargo space is in excess of coal available. Diminished output and heavy requisitions for naval and army transport account for smaller volume at Hampton Roads for New England consignment. While supply of shipping increases from week to week, loss of 25 per cent. efficiency estimated through difficulty in getting and keeping crews, especially in boiler rooms. Railroad situation begins to get action from Washington, but results thus far are meager. Coal at Boston & Maine gateways still being diverted from commercial users. Fuel authorities keep close check on receipts both by rail and water. Anthracite shipments fall off week ending July 6. Much anxiety over inroads of the draft on certified miners. Barges still move slowly.

Bituminous—Efforts at Washington a month ago begin to show results. The receipts of bituminous at the five New England gateways have gradually increased the last fortnight, the average for the first 7 days of July having been 741 cars against the 615 daily average for June. This is apparently the result of the order dated at Washington, June 10, instructing district representatives to direct operators to ship up to 100 per cent. on all New England orders and contracts in hand, after certain important needs in market territory had been cared for. Aside from occasional diversions to relieve congestion at New York piers, nothing has so far been shipped on special requisition by the New England Fuel Administrator, a provision designed to help those steam-users who had been unable to secure contracts, but it is possible that this month will see consignments of this kind started forward.

By this time it is perfectly plain that the weekly movement from the Altoona district alone cannot be worked up to 4500 cars, under the heavy demands in other directions. Bunker purposes at New York are necessarily favored for transport and other service, and the volume for other requirements at the piers has thereby been reduced. Important munition plants in Connecticut have had to encroach on their stocks of high-volatile to feed their steam plants, receipts for their account having fallen off so rapidly during June.

The time when there will be a surplus of coastwise shipping as compared with coal available at the piers is fast approaching. Already there have been cases where steamers under charter by important utilities have been sent to Hampton Roads with no assurance the coal would be furnished. In other cases a number of shippers have had to join in loading part cargoes in order to clear waiting vessels. Large requisitions in favor of byproduct plants and then also the exacting demand for export to the Allies and for transport, the navy, and other Government services have materially curtailed the volume of coal available for this territory. Output in the smokeless districts has also fallen off, and what most operators have foreseen is already taking place. The draft is seriously cutting into the labor supply, especially in the Pocahontas field, where the proportion of non-citizens is very small. The great demand for coke also has its bearing on the supply of run-of-mine, and shipments west are still continuous under special permits. July is likely to make an even more unfavorable showing for New England, than June, and at this writing it is hard to see how ships are to be given dispatch later in the season.

The movement via Curtis Bay and Port Covington has increased, but not to the extent called for by program. The flow of coal is irregular, and already colliers arriving at the piers have been subjected to delay. There are many in the trade who are skeptical of Baltimore & Ohio and Western Maryland movement, and there are many buyers who join in the same opinion. With the New England railroads still moving coal freely from connecting roads, it is hard for them to see much merit in restricting Somerset, Georges Creek and Fairmont coals from the all-rail route.

Were it not for the delay in manning and keeping in operation the 94 steamers now in the coastwise coal service, surplus of shipping would be much more pronounced. It is figured that the loss in efficiency is at least 25 per cent. for this one reason, taking the fleet as a whole. Steamers that were counted upon to make 34 to 38 round trips per year are barely making one trip a month. Time was when certain of these ships would make 47 trips per year. The problem of securing crews and keeping them aboard grows more and more serious.

The railroad fuel situation shows no real improvement. Under the distribution plan announced late in May railroad and Government departments were to be supplied through the Fuel Administration at Washington. The New England roads have found it necessary, however, to make frequent calls on Mr. Storrow, to such extent that not only a considerable tonnage is still being diverted at the gateways from commercial consignees, but hardly a cargo reaches Boston for inland distribution that is not heavily requisitioned for railroad fuel. Even with strenuous efforts the Boston & Maine reserve has increased hardly any. The proper department at Washington has now taken notice of the situation, and two cargoes, amounting to 5900 tons, have been put in process at Baltimore. The summer consumption of the Boston & Maine is about 4700 tons daily.

An interesting meeting was held on July 9 in Mr. Storrow's office with further regard to the compensation to be granted "wholesalers" who do not handle cargoes through their own wharves in such a way as to meet the regulation on "physically handling." A fortnight ago Mr. Storrow fixed the Massachusetts compensation as 23c. per net ton (including purchasing compensation), but since then the New York Fuel Administration has granted 35c., and the Connecticut and Rhode Island administrators have felt it incumbent on them to meet the advance or see coal go to New York consignees. It developed at the meeting that there was a pronounced feeling among shippers against anything that would look like profiteering or that would open the gate to paying bonuses for coal. As an outcome the Massachusetts compensation will probably be advanced to 35c. on shipments out of New York, leaving Hampton Roads deliveries for the present on the 23c. basis for such wholesalers as come within the rule. Washington should now see the point and revoke the celebrated licensing rules 24 to 26, and thereby shut down on any such competition as has already come to light between different territories drawing coal from the same source.

Anthracite—The holiday had its usual effect upon hard-coal shipments, and shipments from the mines since then have fallen off noticeably. The trade is anxious over the continued drafting of skilled anthracite mine workers and one frequently hears the hope expressed that the authorities will find some way to remedy the loss in labor that will presently make itself felt in reduced output. For the first five days in July the average daily receipts of domestic sizes at the New England gateways were 491 cars. Steam sizes averaged 177 cars. Barge movement has slowed up to quite an extent, due chiefly to the precautions still being taken against sea raiders, and partly also to thick weather. It is certain that July receipts will be considerably less in New England than in June.

NEW YORK

Anthracite conditions continue serious. Domestic coals scarce. Organizations ask for State Fuel Administrator. Change to be made in bunker coal pools. Demand for bituminous remains heavy, with free coals hard to pick up.

Anthracite—The continued heavy production is having but little effect on the situation, which is becoming more critical as the season advances, with the increased demand from war industries and domestic users. Labor conditions are not improving. Men continue to be drafted, while others are leaving the mines for higher wages at munition plants, shipyards and other industries. It is claimed that some collieries, because of the labor shortage, are unable to operate more than 50 per cent. capacity.

Locally the situation remains serious. There is a continued scarcity of domestic sizes, including pea, and dealers are thoroughly aroused over the prospects of a shortage here next winter. For this reason the trade is anxious that a State Fuel Administrator shall be appointed at once. They continue to put forth arguments as to the necessity of an appointment being made at once if this market is to have its share of coal. Frequent meetings are being held in various parts of the city, and Dr. Garfield is being urged to fill the vacancy caused by Mr. Wiggin's resignation several weeks ago.

The newest order of the Anthracite Committee, wherein it is directed that water shipments into New England must be on the largest possible scale, and that shipments by rail should exceed one-twelfth of the rail shipments of the 1916-1917 period plus the increased percentages allotted the state into which shipments are made, attracted considerable attention here. The committee says that shippers who have not during April, May and June exceeded one-third of the annual shipments of the 1916-1917 period plus the increased percentages should make up during July the deficiency, in addition to the other rail shipments. This will result, in the opinion of some of the trade in this market receiving less coal than it would if the order had not been issued.

There were 6951 cars of anthracite dumped at the New York tidewater docks for the week ended July 8, as against 7426 cars the week previous, a decrease of 475 cars, due in part to the holiday, on which only 14 cars were emptied.

The New York County Fuel Administrator, Reeve Schley, has issued an order to all retail dealers and shippers prohibiting the delivery of buckwheat No. 1 and larger sizes of anthracite coal to other than the consumers named in Section No. 1 of the order of the United States Fuel Administration of Jan. 17.

Dr. Day, Commissioner of Public Markets of this city, has announced that he has closed negotiations with the DeJulio Co., of 220 Broadway, whereby this city will receive 300,000 tons of coal from the Schuykill regions to take care of the needy next winter. Deliveries are expected to begin soon after the formal contract is signed.

The steam coals are scarce, with a good demand. Buckwheat No. 1 is hard to pick up, and with the new order of Mr. Schley is not expected to increase in supply.

Current quotations per gross ton f.o.b. tidewater at the lower ports, follow:

	Circular	Individual		Circular	Individual
Broken	$6.50	$7.25	Pea	$4.90	$5.65
Egg	6.10	6.85	Buck	4.85	5.60
Stove	6.35	7.10	Rice	4.35	4.80
Chestnut	6.45	7.20	Barley	3.85	4.00

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice and barley are not fixed by the Government.

Bituminous—The local situation continues serious. Stocks are low and there is small opportunity for consumers to lay in an extra supply. Large consumers and regular customers are able to obtain sufficient to keep their plants going, but are not able to store any for future use. Car supply shows some improvement, but the labor situation remains a menace.

There is plenty of bunker coals to be had; in fact, some shippers are said to be over-stocked. This supply will probably be reduced shortly, and the quantity of coal available for commercial uses increased by the issuance of an order on Monday by the United States Fuel Administration to the effect that coals in Pools Nos. 1 and 9 are to be used for transatlantic ships and that coals in Pools Nos. 4 and 10 are permissible for coastwise and river steamers.

Dumpings of bituminous at the local tidewater docks for the week ended July 8 show that 7089 cars were dumped as against 7228 cars the preceding week, a decrease of 139 cars.

The order issued from Washington a couple of weeks ago directing that 900 cars be sent daily from the central Pennsylvania fields into New England is still in force, with the result that this market is not receiving as much coal as it ought to get.

In regard to the margin of 35c. per ton on coal physically handled by jobbers, Ellery B. Gordon, assistant to the State Fuel Administrator, has written to Charles S. Allen, secretary of the Wholesale Coal Trade Association, explaining further several points in connection with the ruling. He says that sales agents who obtain this commission from the mines will be expected to take this margin minus the amount of commission they received from the mines; that the order is a provisional one and quite liberal, and that he wishes to caution wholesalers from taking advantage of it where their conditions of operation do not justify the full margin of 35c.; and thirdly, that it is not the intention that the ruling will bring about a competition between sections, but that irrespective of the margins permitted at various points served by New York wholesalers they will place their tonnage where it is needed most without regard to margins, following their usual proportionate distribution as far as possible.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-mine	3 08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite tonnage does not improve. Dealers' yards empty. Making receipts go as far as possible. Some domestic buckwheat demand. New light and power regulations. Increased retail prices account freight raise. Operators call on public to conserve fuel. More statistics ordered from retailers. Bituminous slightly improved, over previous week. Talk of changed price fails to attract attention. Stocks being accumulated.

Anthracite—From the retail standpoint it cannot be said that any noticeable progress has been made lately toward filling bins, but there is an apparent feeling of confidence that conditions are about to improve. Larger shippers, while they expect much heavier shipments into this market, hesitate to give the dealers much encouragement for fear something will happen to change their plans, or that they will be besieged by the retailers for more coal than it will be possible to ship. Thus far this month tonnage receipts are even lower than the average for June, much of this being traceable to the Fourth of July holiday, which materially cut production.

Reports recently filed with the local fuel administrator show practically no prepared sizes in the retail yards, with an enormous tonnage to be delivered. A number of dealers have gone into the market for No. 1 buckwheat coal for domestic trade, and are endeavoring to secure a stock. This size has not been sold in any appreciable quantity for this purpose, but is being sought for emergencies. The dealers who are showing an interest in it feel that it will be good business to stock the coal in the empty spaces they now have, as they feel there will be no difficulty to move it when winter arrives.

Lightless nights have again been ordered, and other limitations placed on the use of electric current, effective with the 10th inst. Elevator curtailment and the staggered, or "skip-stop," system of trolley service has also been ordered for the 15th. Many of the commercial bodies here are much opposed to the skip-stop system on the street railways. In the curtailment of illumination the elimination of all window display lighting becomes a law instead of a request, as last year. Electric energy for power and lighting, as well as gas for cooking and heating, will thus be regulated and their consumption greatly reduced.

This week the fuel authorities have given much consideration to the alleged faulty reports of owners of buildings who had applied for permits to receive coal. There are cases against 87 owners of buildings who it is claimed have rendered false statements as to the amount of coal on hand and the amount consumed last year. Action in court will be taken against all those who are unable to satisfactorily explain their reports.

An announcement was made this week of the total shipments for the first quarter of the Government coal year, wherein it was shown they fell short of 600,000 tons, whereas 700,000 tons were needed.

Retail prices as quoted by the dealers have now reached the highest point since the big strike of 1902. One representative firm, which is supplied by the big companies as well as the independents, this week quoted as follows: Broken, $9.85; egg, $9.45; stove, $9.75; chestnut, $9.85; pea, $8.20; buckwheat, $8.

In comparison with these figures it is interesting to note the new figures issued by the chairman of a fuel committee in one of the suburban districts. The new prices are fixed at this time owing to the increase of 45c. in freight rates, and the suburban quotations are made for dealers handling both company and individual coal;

	Egg	Stove	Nut	Pea
Company	$9.00	$9.25	$9.25	$7.75
Individual	9.75	10.00	10.00	8.50

It was thought that all possible variations of statistics bearing on the retailers' business had been asked for, but the dealers have now been called on for still another statement. Late in the week they were in receipt of communications from Washington, inclosing forms of statements for them to fill out showing the amount of coal on hand during the week just past, together with the amount delivered and the tonnage en route. This statement is to be made out in duplicate each week, and one copy sent to the national administration at Washington, while the other is to be sent to the state fuel administration in this city.

There is no appreciable change in the steam coal situation. All sizes continue to be fully taken, with only the least possible leeway on barley coal, and this only in occasional instances. With the continued fair shipments of bituminous there is still little market locally for culm, and most sales are made at the $1 figure, although some of the companies insist on $1.25 for their shipments, the most of which goes to commission houses. It is noticeable in this territory that the manufacturing plants are storing considerable of the anthracite steam sizes, and even the non-war plants are getting good consignments and will likely have all the coal they are allotted for the year by the time snow flies.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—Fairly good shipments have continued to come out, although the car supply is far from the liking of the operators. It is only fair to state, though, that this week there has been a slight improvement in this respect, as we have come across operators who state they have received a little better than 50 per cent., and some even as high as 60 per cent. of rating, as compared with an average of about 50 per cent. for the previous week.

The preferential order of 4500 cars per week for New England continues in force and at the moment there is no prospect of the order being rescinded for some time to come.

The operators seem to be but little disturbed at the agitation for a price reduction caused by the report in Washington of the alleged profits under Government price fixing. As a matter of fact the producers do not see how the price can be reduced, with the likelihood at any time that the workmen will ask for increased pay due to the manner in which the cost of living has mounted in the last six weeks.

BALTIMORE

Big slump in movement of soft coal noted. Inspection at mines for bad coal apparently not very rigid. Anthracite men report light receipts and in many cases are refusing more orders. Work or fight order both hurts and aids.

Bituminous—A decided falling off in the receipts of soft coal here is noted. Handlers of the fuel in this section report that there has been a decided decrease in direct movement of fuel and an almost complete elimination of the diversions that had kept this section well supplied for a few weeks. The fact that the lines north have been cleared of much congestion, while local freight yards here have suffered a jam of freight other than coal, has militated against the receipt of any great quantity of diverted coal. The preferential list of deliveries to steel works and for railroad fuel, much heavier in the past two weeks than for some time previous, has also absorbed much of the flow of fuel from the mines. The result here has been that a number of the industries have been forced to go into the slender surplus stocks they had managed to amass during the fairly free supply period. Numerous requests for fuel that have come to the Maryland Fuel Administrator have been sent to the district representative for assignments, but the response has been extremely light.

Anthracite—Dealers here report receipts comparatively light. The movement to this section continues not only below the 10 per cent. increased allotment basis, but below the standard set at this time last year, when there was much more coal in cellars and in yards of dealers than at this time. Numerous dealers are now figuring that they can not possibly deliver more than the two-thirds business of the orders already on their books before winter, and the list of those refusing to take more orders at present constantly grows. The public, too, is becoming more and more uneasy as they find increasing difficulty in even getting promises of partial delivery before October or November.

Lake Markets

PITTSBURGH

Doubts as to magnitude of prospective shortage. Labor supplies uncertain. Narrow market.

In view of the heavy production of coal, some observers are wondering whether the shortage, or prospective shortage, is not being exaggerated. Allowance is made, of course, for the unprecedented consumption of many industries, but on the other hand it is held that measures of economy should count for a great deal, and the high cost of coal must be a great incentive, apart from the regulations and vigorous pleas of the Fuel Administration.

Car shortages continue in the Pittsburgh district, but there is also some labor shortage, and it is doubtful whether an increased car supply would result in a large increase in production. It is pointed out that there is this important difference between present conditions and those of the early months of the year. Then cars were not only short, but in irregular supply, the result being that miners frequently came to work and found nothing to do. Now the case is different. Car supplies are regular, even though not adequate.

The miners are not producing as much coal as they could by working full time, but they are probably producing nearly if not quite as much as they are disposed to produce until fresh measures are taken to stimulate their activities, contingent of course upon there being the added car supply. By the last two weekly reports of the Geological Survey western Pennsylvania shows a deficiency of about 17.6 per cent in production, 11.5 per cent being attributed to car shortage and 3.6 per cent to labor shortage.

The market is still a narrow one, nearly all the coal produced going out on contracts or Government requisitions. Brokers are still able to secure from consumers a commission on the major portion of the small tonnages of coal they can secure for sale. The market remains quotable at the set maximum prices: Slack, $2.10; mine-run, $2.35; screened, $2.70, per net ton at mine, Pittsburgh district, brokers being permitted to charge 15c. brokerage to consumers.

TORONTO

Prices increased owing to increased freight rates. Coal coming forward freely, but dealers much behind with deliveries. Consumers unable to place new orders.

There is practically no change in conditions. Coal is coming forward freely, but the supply is entirely inadequate to enable dealers to overtake large orders on hand. Customers are all anxious to lay in supplies for the winter, but dealers as a rule are refusing to accept new orders. Quotations for best grades per short ton are as follows (subject to an increase of 45c per ton to cover increased freight rates when new orders are filled). Retail anthracite egg, stove, nut and grate, $10, pea, $9; bituminous steam, $8.50; slack, $7.50; domestic lump, $10; cannel, $13. Wholesale, f.o.b. cars at destination, three-quarter lump, unprepared, $6.11: prepared, $6.31; slack, $5.18.

BUFFALO

Still the shortage report. All varieties of coal sure to be scarce. Consumers agree and try to stock up. Cars are fluctuating. Anthracite falling off.

Bituminous—Not much change has taken place in the trade. The movement may be called normal for war time, which is of course under much restriction and with prospect of more of the same thing. Nobody looks for an easy time next winter, and the owners of all sorts of factories are wondering if they will be allowed to run at all. It is hard to get much idea of the future course of the authorities. In fact it will be governed by the amount of the shortage, for a shortage is certain.

It is still hard to get a price list to which all will agree, but the following is as authentic as it can be made: Thin-vein Allegheny Valley, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; cannel, $6.15; smithing, $5.85, all f.o.b. Buffalo, per net ton, with jobbers' profit added.

Anthracite—Following the general plan of summer distribution, the city supply is much less than it was early in the season. Many consumers are complaining that their orders, given in March, are not yet filled by the distributors, and other authorities say that no one has reason for complaining, as the prospect is for a usual supply. The real

difficulty is with the natural gas supply, which nobody can size up, so that the people with gas apparatus in their houses are unable to determine what to do. They prefer gas to coal and will probably still use it if it is to be had, even though the price is advanced from 30 to 35c. per 1000, as the company demands. A guarantee supply is what is asked now.

The anthracite shippers are doing their best to keep up the lake movement, but with a holiday last week the loading was only 77,500 net tons, of which 25,400 tons cleared for Milwaukee, 21,400 tons for Duluth and Superior, 18,000 tons for Chicago, 7100 tons for Fort Williams, 3000 tons for Hancock and 2600 tons for Houghton.

The shipment for the season to July was 866,156 tons, as against 1,123,495 tons to the same time last season. June shipments fell off 86,450 tons from the amount in June last season.

CLEVELAND

Holiday cuts receipts of bituminous coal. Mine equipment hard to get. Consigned car statistics. Coal receipts at head of lakes.

Celebration of the Fourth of July at the mines in the No. 8 district, and the consequent slackening of work on Friday and Saturday, cut heavily into receipts of bituminous coal here. Except for this factor, the movement showed an improvement over the preceding week. With the wiping out of the preferential car-supply system, more equitable distribution of cars and an increased output is expected. Car supply on nearly every road showed improvement. The general feeling among operators is that stocking of coal at industrial plants in lower lake cities should be stopped until the demands of the Northwest are better met. In some cases operators report difficulty in getting mine equipment ordered before the priority plan of distributing steel was adopted.

In the week ended June 29 the operators belonging to the Pittsburgh Vein Operators' Association of Ohio consigned 1626 cars to railroads, 3193 to the lake, 1533 to Ohio, 246 to Michigan and Indiana, and 87 to Canada. Mines on the Baltimore & Ohio shipped 6685 cars, on the Pennsylvania 3290, on the Wheeling & Lake Erie 1584, and on the New York Central 169. For the month of June the car supply in the Pittsburgh vein district was about 37 per cent short. By roads the shortage for the month was: Baltimore & Ohio, 41 per cent.; Pennsylvania, 36 per cent., Wheeling & Lake Erie, 33 per cent., and New York Central, 16 per cent.

On the average about 3200 cars of bituminous have been dumped in the week into upper lake carriers. Fourth of July celebrations are beginning to be felt, and some freighters have been forced to go to three docks in order to get a full load. Receipts of coal at the head of the lakes for June are shown to be: Bituminous, 905,700 tons, and anthracite, 238,500. This compares with 991,603 tons of bituminous in June, 1917, and 221,278 tons of anthracite. Total receipts of bituminous up to July 1 are 1,992,200 tons, and anthracite, 374,600 tons, compared with 1,692,540 tons of bituminous and 440,245 tons of anthracite in the corresponding period of last year. Statistics just compiled show that in June 1,649,088 tons of bituminous and 288,947 tons of anthracite moved westbound through the Soo canals.

DETROIT

Detroit's coal receipts are still light, with mine-run holding the lead. Domestic buyers delay. Lake trade shows favorably.

Bituminous—Much dissatisfaction is expressed among jobbers and wholesalers in the Detroit market concerning their inability to get coal moving into the city in larger quantity. Unless a heavier movement develops in the near future, the coal men fear there will be a serious shortage of supply during the coming winter. Attempts to improve the present supply seem to meet little success. While car supply is reported more satisfactory in many of the mine districts, there are still complaints from sections of shortage of transportation facilities, holding back production and shipment. Reports of production being curtailed by shortage of mine workers also are heard.

Inquiry from consumers of steam coal continues active and the available supply is taken so quickly that jobbers say it is almost impossible to find free coal on tracks in or around Detroit for filling emergency rush orders. Moderate progress has been made by some of the large users of steam coal toward creating reserve piles. Little opportunity is afforded, however, for selection of stock as the shipments received are chiefly mine-run, with only small amounts of slack and prepared sizes.

Sizes favored for household use are said to be forming only a small part of the shipments, and some of the dealers have found it difficult to obtain anything like an adequate supply. A moderate degree of success is attending the work of retailers in attempting to impress on customers the desirability of stocking up now for winter household needs. The consumers are being warned that limitation of anthracite supply and elimination of other substitutes make it probable chief reliance must be placed on domestic bituminous.

Anthracite—Little improvement is reported in the movement of anthracite into Detroit. Daily receipts are said to average under 40 cars, and retailers have been unable to get much of any stock in their yards. Orders placed three months ago remain unfilled.

Lake Trade—Though not averaging up to the loading that will be necessary to realize the schedule for lake shipments before cold weather, there was a better supply of coal at loading docks the latter part of last week and early this week. The movement of anthracite to Lake Superior ports in June was 268,947 tons, the lightest for the month since June, 1912.

COLUMBUS

A strong demand for all varieties of coal still characterizes the coal market in Ohio. There is some let-up in the domestic demand, but the steam and lake trades are absorbing all the fuel produced.

The coal trade in the Buckeye State continues active in every particular. Demand for tonnage from all sources is strong, and production is not yet up to expectations. During the past week there was a fairly good production, when the holiday is taken into consideration. All available tonnage is quickly taken up, and operators can dispose of their tonnage readily. The tone of the trade is generally satisfactory.

Domestic trade is still active, although there is not the feverish demand noted several weeks ago. This is accounted for by the statement that many domestic users are on their vacation trips and are not buying coal as formerly. Another reason is that many of the users have a full supply of fuel for the coming winter, and that the acute demand is now passed. But dealers are still having a good run of orders. West Virginia grades are in the best demand, though a large majority of the consumers are ready to take Ohio-mined grades. Retailers still have orders that will keep them fairly busy for the coming month. Their surplus stocks are low, and little opportunity is afforded to increase them. Retail prices are firm at the new levels, which include both the advanced freight rates and the new government price schedule. Anthracite is scarce and sells in the neighborhood of $10.70. Hocking grades sell from $4.80 for thick-vein to $6.20 for thin-vein.

The steam trade is strong, and consumers are taking advantage of the slight lull in domestic business to increase their surplus stocks. This is especially true of the larger consumers. Railroads are taking a good tonnage, and some are trying to stock for the heavy fall use. Many of the schools have now been supplied and public and state institutions are looking after their fuel supply. The threshing season is now at hand, and a considerable tonnage of mine-run is being distributed to various sections to take care of the grain harvest promptly.

Lake trade is still active, although records show that there is a shortage of between 1,500,000 and 2,000,000 tons on lake shipments compared with pre-season estimates. This is accounted for because of the late opening and of car shortage and labor difficulties. Lake shippers look for a priority order to be issued later in the season.

CINCINNATI

Diminished receipts caused by holiday, but other conditions are favorable, including car supply. Lake movement continues heavy and steady.

The Fourth of July holiday, with the reaction of the following day, caused the usual loss of production at the mines, although some instances are reported where the men voluntarily worked part of the holiday in order to keep coal moving. Aside from this loss, conditions are all favorable to increasing production, as the car supply is much improved and bids fair to continue its betterment, while miners seem generally to realize that their work is among the most important in winning the war, and in consequence labor troubles have been reduced to the vanishing point. Consumption for industrial purposes is large, but shipments are beginning to gain on current consumption, and storage for future use is therefore possible for local concerns, as well as for those in the Northwest, furnished via the lakes. The lake movement is assuming record-breaking proportions with the steady shipment of coal from the West Virginia section set aside for that purpose exclusively, and it is becoming more and more evident that unless some unforeseen interruption to production and movement of fuel occurs, the Middle West and the Northwest will be in the best position for the winter ever known, even in ordinary times.

LOUISVILLE

Domestic stocking demand considerably in excess of supply, with retail yards empty and dealers holding orders for several thousand tons. Slight surplus of screenings and steam coal. Car supply satisfactory at mines, but labor shortage serious.

In the eastern Kentucky fields considerable improvement of properties of operating companies is under way, although there are practically no new mines going in under Government regulation. Many companies are increasing their capital in order to make improvements to facilitate operations. The car supply is generally good, and no complaint is heard on that score, but all mines are short of labor.

Practically the same situation exists in western Kentucky, which has been shipping capacity production and unable to supply the demand. Little eastern Kentucky coal, with the exception of some low-grade Hazard coal, has been coming to the Louisville market, resulting in the demand for western Kentucky being extremely heavy.

More coal is being stocked this year by domestic consumers than ever before. It is claimed that deliveries during May and June were ten times heavier than during any previous spring months on record. One large concern reported that it had orders on its books for about 5000 tons of coal, while two of its largest yards are empty. At this season of the year 2000-ton orders would be considered heavy. The retailers are all snowed under on domestic orders, and are not promising any prompt deliveries. More cash business is developing than usual, and several dealers believe that it is only a question of time before retail business goes on a cash basis, credits now being on a thirty-day basis.

Steam consumers are well taken care of, and there has been some surplus steam coal, including screenings, on the market. A few domestic consumers have been taking such coal, but consumers in general are afraid of stocking west Kentucky mine-run and screenings, as this grade of coal has a habit of firing. However, in small tonnage lots for domestic consumption such coal doesn't fire, but the consumer cannot be convinced of the fact.

BIRMINGHAM

Railroads active in closing fuel contracts. Industrial demand for steam coal strong. Domestic grades being eagerly sought. Output as a whole has improved only slightly. Still a question of labor.

Representatives of the various railroads centering in this district have been busy the past week endeavoring to place orders with the mines for their 1918-1919 coal supply. The demand from industrial sources has been brisk and the supply with many plants has been inadequate and uncertain. Data which are now being compiled on the essential industries in this zone are expected to eliminate many consumers from participation in the coal supply and will afford a measure of relief to the preferred class.

Both the wholesale and retail domestic markets are active and much coal is being distributed and stored. However, retailers are not receiving anything like their requirements and householders are thus being greatly delayed in laying in their winter requirements.

The labor supply is retarding coal production greatly and numerous new operations fail to add to the output the tonnage that would otherwise be easily gained. Practically normal outputs were obtained at many mines throughout the district on July 4. However, daily productions are so spasmodic that it is difficult to discern much improvement as a whole.

Coke

CONNELLSVILLE

Holiday makes no trouble. Coke surplus a possibility in near future. Production increased.

For the first time in history when the blast furnaces were really active there has been no flurry by reason of Independence

Day. In other years, except when pig-iron production was light, there has been scurrying for spot coke before Independence Day, with a sharp advance in the market. This year the furnaces picked up such extra supplies as they could, with the limitation that they could not pay above the Government maximum, and this week they have found themselves comfortably fixed as to coke. If there was a curtailment in shipments last week it was made up by stocks accumulated. An effort was made by all operators, however, to avoid loss of time, by working on the eve of Independence Day.

A few blast furnaces are idle that might perhaps be in operation if there were more coke, but there are practically no cases of operating furnaces being short of coke, and some of the furnaces report moderate reserves. Predictions are made by some close observers that if present conditions continue for a few weeks there will be a surplus of coke in the market, and that might possibly result in some shading of the Government price. It is quite certain there is more profit in coke than in coal at the present set prices. Up to the present time nearly all the free furnace coke that has developed has been picked up promptly by furnace representatives in the region, never reaching the stage of being openly offered in the market. Foundry coke, however, is offered with some freedom, as the operators generally make more 72-hour coke than the foundry trade can consume, and the $7 price cannot be charged blast furnaces. More often than not brokers secure a commission from operators for the sale of foundry coke, but such instances in the case of furnace coke are very rare. The market remains quotable at the set prices: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1-in., $7.30, per net ton at ovens. Coke screenings from old dumps are bringing up to $6.50, for fuel purposes, and better preparation may bring somewhat higher prices, up to the $7.30 maximum prescribed.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended June 29 at 353,590 tons, an increase of 7640 tons over production in the previous week, which was record since the first of the year.

Buffalo—The jobbers in this market are still unable to get beehive coke to any great extent, but the demand for it is good, though the Canadian furnaces are not up to the average here. Dealings are with the coke producers direct for the most part, but byproduct coke is moving freely. Some jobbers report sales of a coarser coke than they have formerly obtained. While the breeze price is still $2.75 at the producing point, the larger sizes sell all the way to $5.50 a ton and the demand is much above the supply. Makers of illuminating gas are asking $8.50 a ton undelivered, and report that they are obliged to use practically their entire output, though they prefer coal.

Middle Western

GENERAL REVIEW

Federal Trade Commission report excites comment. Labor question still serious. Demand for coal keeps up well.

The recent report of the Federal Trade Commission to Congress, in which coal operators were termed "profiteers," has caused a lot of comment among mining men in the Middle West. At this time, when 90 per cent. or more of the operating companies are up to their respective necks in difficulties of labor, transportation and finances, and at the same time bending every effort toward increasing their production, the report comes somewhat as a surprise.

There is some optimistic talk in the trade about help on the labor question from Washington. A number of the optimists think that Mr. Garfield has enough influence with the President to overrule Major General Crowder's order which does not exempt the miners. The belief is that the miners will have to be exempted or the output of the mines will be lessened to such an extent that the country will suffer a serious loss.

Local conditions throughout the Middle West are practically unchanged; the car situation is perhaps a trifle better, but the labor question is as serious as ever. The demand for coal, both for domestic and steam use, keeps up steadily, with most operators having enough unfilled orders on their files to run them for the next six weeks without taking on any additional business.

CHICAGO

Production does not keep pace with demand. Domestic situation unchanged. Several cargoes of anthracite moving toward Chicago.

The demand in Chicago for steam and domestic coal, all grades, still continues to exceed by a large figure the production. A number of large steam buyers were of the opinion that there would be a decided slump in mine-run and fine coals shortly after the advance in railroad rates went into effect. Much to their chagrin there have been no signs to date of the steam market weakening to any appreciable extent. It is true, however, that screenings are sold a little more freely than they were a week ago. The efforts on the part of a number of purchasing agents to get their plants under cover so far as the coal question is concerned has proved unavailing, and these men are still making the rounds of the coal offices trying to place their orders.

The domestic situation is practically unchanged, the dealers trying every possible means to prevail upon the operators to accept their orders.

It is expected that the anthracite situation will be relieved some in the near future because there are several cargoes of anthracite moving toward Chicago, and these are expected any day.

Quotations in the Chicago market are as follows, per net ton f.o.b. cars at mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55

No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

There is no change in the retail price, and the prevailing market on Standard is much the same as last week, as follows:

Williamson and Franklin counties, $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

There is a shortage of water throughout the Carterville field that is keeping some plants from getting out a better tonnage, and some washing plants are idle. The railroads still continue to take coal heavily out of this field, although it is understood there is to be a 60-day suspension of railroad loading, in which time this coal is to be shipped to Chicago and northern cities for domestic purposes.

In the Mt. Olive field the working time is fairly good. Equipment is rather plentiful and the labor problem is not so bad as in some other places. The tonnage here is just about equal to the demand. In the Standard field the labor problem is a serious one. The miners want to work at mines that give them steady employment, and some operators are unable to move the tonnage produced.

MILWAUKEE

Anthracite price schedule held up pending investigation as to proper margin of profit. Wisconsin allowed more Illinois coal.

Notwithstanding a fortnight or more has elapsed since the scale of prices for anthracite coal at Milwaukee was publicly announced, no bills have been rendered at the new scale, as the state fuel administration directed a suspension of billing until a proper margin of profit had been definitely determined.

For sixty days beginning July 1 Illinois bituminous screenings will be allowed to move to the entire State of Wisconsin, and the state fuel administration is urging manufacturers to take full advantage of the dispensation so that coal received by lake may accumulate on the docks for use later in the season.

The Central Board of Purchases of the city has entered into contract with a pool of local dock companies covering 65,000 tons of soft coal at prices ranging from $5.74 to $6.50 per ton. No bids on anthracite were received. Dealers who handle bituminous coal by rail underbid the dockmen, but the board decided that it would be unwise to depend upon rail supplies. The bid of the dock men on 51,000 tons aggregated $342,363 and that of the rail men $305,653. The rail men refrained from bidding on supplies to some of the city utilities requiring a long haul, but declared they would include such points if awarded the contract.

Since last week 18,125 tons of hard coal and 133,766 tons of soft have been received by lake, making the total receipts since the opening of navigation 157,772 tons of hard coal and 923,307 tons of bituminous.

ST. LOUIS

The market is somewhat inactive. An unusually heavy surplus of Standard coal on the market and steam is dragging. Cars are plentiful on account of zone restrictions. Carterville getting more plentiful. Country demand fair. No outside shipments. No eastern or Arkansas coal coming in.

The local situation is much easier. For the past week there have been an unusually heavy surplus of Standard coal on the market of all sizes, and screenings and mine-run are dragging, with no prospect of conditions improving unless the railroads begin to buy.

Conditions in the Carterville field are favorable with the short car supply, but not so bad as it has been at times. The labor problem still continues to be serious.

SEATTLE

Revision in freight rates boosts price of coal 20c. Wider use of Washington blacksmith coal demanded. Penalty clause for miners who lay off adopted by organized labor.

The price of coal mined in western Washington mines has been advanced 20c. per ton, owing to the advance in freight rates. This is the second raise in price in the recent past, the last being a lift of 10c. per ton. If the teamsters in Seattle are successful in pushing their demands for more wages, retail prices are expected to go up about 50c. a ton more. The Fuel Administration office has notified local industry to use Washington blacksmith coal in preference to the Pennsylvania, imports of which will be stopped in the near future. D. C. Botting, of the local fuel administrator's office, states that Washington blacksmithing coal is of the highest quality and has been used for years by such firms as the big Tacoma car shops of the Northern Pacific, the Oregon-Washington R. R. and others. Blacksmithing coal to the extent of 1000 tons a month can be produced by the mines at Wilkeson, if necessary, the fuel administrator estimates.

At the recent convention of the representatives of District No. 10, United Mine Workers of America, it was voted to restore the penalty of fines for those who took time off from work when it was not necessary and thus contributed to the shortage of coal which now exists. When some of the mines shut down in April men working irregular hours, as well as their employers, were relieved of the penalty feature of the last agreement between the unions and the operators. District officials now declare that these men are too well satisfied with the wages they receive and are not working as steadily as the union believes they should. The order will affect 6000 miners.

COAL AGE

Volume 14 New York, July 20, 1918 Number 3

Mechanical Energy versus Human Muscles

IT HAS been stated that the mines of this country must produce between 75 and 80 million more tons of bituminous coal this year than every before or some of our industries will be forced to go on short fuel rations. Of the two alternatives, that of increased production is the more desirable in every sense.

Increasing the output of coal is much like multiplying a vulgar fraction—we may either mutiply the numerator or divide the denominator. In other words, we may either increase production by working the present labor supply under existing methods a greater portion of the time, or we may change the means, methods or manner of working but expend the same amount or less of physical exertion.

To increase the amount of manual labor of any individual in a given length of time or to greatly increase the hours of labor both have their obvious limitations. Nature will not stand being driven too far. A change of method, on the other hand, usually entails a considerable increase in mechanical equipment; but the results attained often pay handsome dividends upon the initial outlay.

As an example of how mechanical equipment may aid physical effort, let us consider the following: A man traveling on foot can cover, say, 20 miles a day. We change the process of locomotion—substitute ball bearings and rubber tires for shoe leather—place the man on a bicycle, and with the same muscular effort he can cover 60 miles a day. Let us now make another substitution and place the man on a motorcycle. He is now able to travel 200 miles a day with even less effort than he walked 20 miles. Thus by the aid of mechanical help the man's "mobility" has been multiplied by ten, yet his physical effort has been decreased.

All the operations involved in the production of coal are not so readily solved by the application of mechanical energy as is the simple case of locomotion cited above. Many of them, such as undercutting for instance, have already been accomplished, while others still await solution or have as yet been only imperfectly or partially solved.

One important consideration to remember when considering the installation of mechanical equipment is that man's muscles are so weak that they can but little more than move his own limbs; his brain is big enough and active enough to guide and control the largest and most complicated machines that he has yet devised.

Without sufficient fuel our war effort must slow down. There is but one way to produce more coal with fewer men, and that is to substitute mechanical energy for human muscles. Have you done your level best to increase output at your mine by putting in plenty of equipment? Every eye in America is focused on the producers of coal.

IDEAS AND SUGGESTIONS

Simple Face Conveyor

BY H. G. DAVIS
Kingston, Penn.

The mining of the thinner or poorer quality beds of anthracite in the Lackawanna and Wyoming fields brought with it new and perplexing problems. The depleting also of the operating forces by the war and the increased demand for coal has resulted only in adding seriously to the perplexing situation already existing.

The coal mining companies have therefore been placed at their wits' ends to devise means for keeping

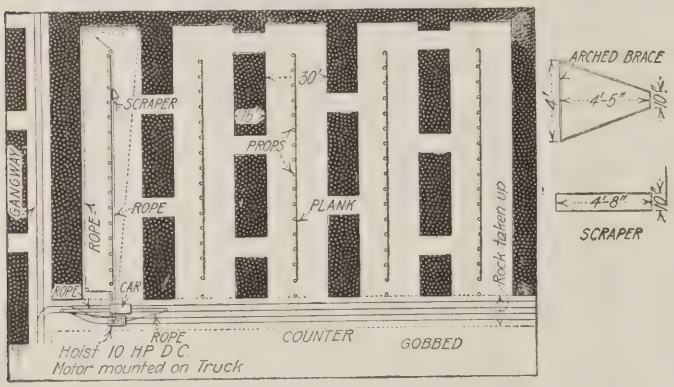

DIAGRAM OF SCOOP AND ITS OPERATION

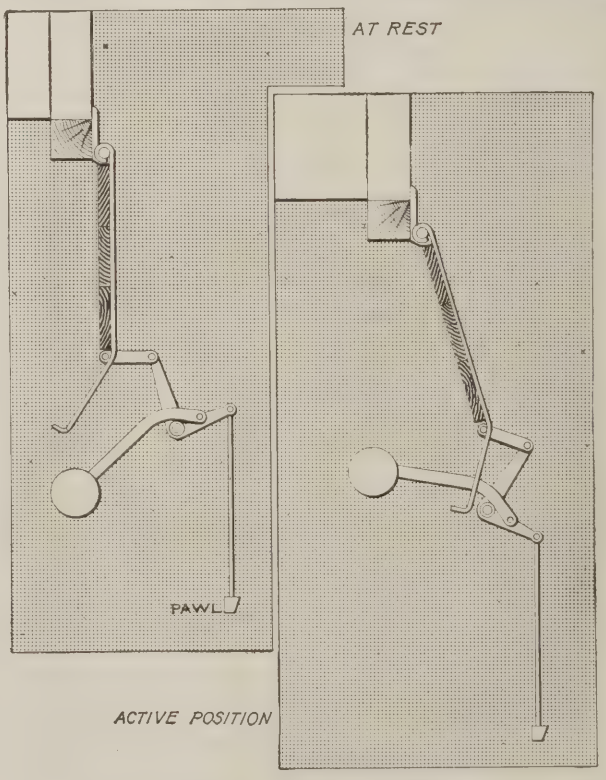
up anything like a normal output. The Delaware & Hudson Coal Co. has successfully introduced in some of its mines in the vicinity of Scranton a loading arrangement that appears to be giving satisfactory results.

The scraper or conveyor used in bringing the coal from the face to the gangway or loading road is made of ¾-in. steel, and is reinforced at the top and bottom with light angle iron. It is V-shaped, 10 in. wide at the rear end, 40 in. wide at the front, 4 ft. 5 in. long and has no bottom. It is braced across the top by a piece of ½ x 2-in. iron, in a bow shape, so as not to interfere with the releasing of the load at the car, or discharging point, as shown in the accompanying illustration.

I am informed that with this arrangement the Delaware & Hudson Co. is loading out 25 to 30 cars per shift of eight hours, from a panel of four to six chambers in a bed 38 in. thick. This system can be successfully used in the thicker beds of this region, and the man power employed thus made much more productive.

I have been informed also that Cadwallader Evans, Jr., who is now with the International Salt Co. as general manager, is applying this method for loading salt in the mines of northern New York. I might incidentally state that Mr. Evans was the first to introduce this system in the coal mines, and I am under the impression that he has patented some parts of the equipment.



As already stated, there is no special reason why this invention could not be used more universally for loading anthracite coal, particularly in thin beds, so as to avoid the necessity for expending the large amount of energy now wasted on the top and bottom rock cut necessary to make height for mine cars, and in the thicker beds in which the pitch is not enough for the coal to run on sheet iron and is too heavy for cars.

There are several other face conveyors on the market which are quite successfully used in connection with the undercutting machine. The adaptability of all of these should be investigated by the employers of labor today, in order to assist in a greater production during the present crisis.

An Automatic Deflector

There is always danger to men working at shaft bottoms—especially at times of caging cars—from pieces of coal or other objects falling down the shaft. The open space between the cage top and the side of the shaft may be a source of danger to men passing underneath when the loaded car is being run onto the cage. At such times anything falling down the shaft may strike unprotected workmen.

To remedy this state of affairs, the Madison Coal Corporation, of Illinois, devised a scheme which was

TWO POSITIONS OF AUTOMATIC DEFLECTOR

installed at its No. 6 mine near Divernon, Ill. An automatic deflector was attached to the collar at the shaft bottom on the side of the shaft nearest the loaded sidings, at each compartment. The device is shown in the accompanying illustration at rest on the left and in

active position on the right. Each deflector constitutes a 3 x 6-ft. wooden shield.

In operation, when the cage about reaches the bottom landing it engages a pawl which connects by rod, bell crank and connecting link with the bottom of the deflector. The shield is thus moved into the active position shown by the illustration, thus roofing over the open space between the cage top and the side of the shaft. When the deflector shield is in the active position it intercepts falling objects and protects the men passing underneath it.

The policy of the more progressive companies is to guard against accident or injury to their employees in every practicable way. Automatic safety devices often do more than conserve life and limb, they may bring about greater efficiency through increased security.

Portable Saw for Mine Use

Instead of taking the wood to the saw, the mill is moved to the timber at the Glen Carbon plant of the Madison Coal Corporation, of Illinois. At this mine considerable prop timber is stored at the plant, as it is used in large quantities underground. The prop timber is stacked on the ground so as to be convenient to a track which runs the length of the yard.

A portable home-made sawmill runs on this railroad-gage track, as shown in the accompanying illustration. A 36-in. circular wood saw and a 25-hp. motor are mounted on a truck built of 8 x 10-in. sills. A pair of wheels at each end and a house superstructure to protect the machinery and operating workman in bad weather complete the outfit. A feed wire through the yard permits of electrical connection at any point, for power for the motor on the truck.

The circular saw can be seen at the front left-hand corner of the truck, directly over one of the track wheels.

PORTABLE SAW IN TIMBER YARD

Suitable arrangements are provided for holding the timber being cut. The mines use so many props that the timber covers a lot of ground, and it is much easier to move the saw up as the timber is used than to handle timber over a large yard to a stationary mill. At the Glen Carbon mine one prop is required for every 3½ tons of coal mined; at the No. 6 plant of the Madison Coal Corporation one prop is used for every 10 to 12 tons produced. Ordinary mine requirements in this section call for props with a 4-in. diameter, small end, as a minimum. Where smaller timber is received in a lot, it is utilized for mine track ties.

Keeping Track of Miners' Safety

By Ernest L. Mandel
Editor, "Magyar Munkaslap," New York City

In my travels through the coal fields of southwestern Virginia I noticed with interest the practice of the Stonega Coal and Coke Co., of Big Stone Gap, Va., which operates 16 mines at seven plants, all the plants being electrically operated. C. G. Duffy, the superintendent,

Stonega Coke and Coal Company

			M								

THIS RECORD SAFEGUARDS MINER'S LIFE

has an interesting form for recording the condition of the roof and the means taken and the provisions on hand to protect the miners. This form was prepared by R E. Taggart, the general manager of the company, and it appears to have done good work in prevention of accidents. The Stonega plant, at Stonega, Va., for instance, in 1917 mined over a half a million tons of coal without a single fatal accident. The record this year up to the close of April was equally good.

Backing Up Our Soldiers

The first thing they teach soldiers is teamwork—the "get-together" idea. For it's teamwork, and teamwork alone, that wins battles.

So it behooves us war savers to "get together" too. Wherever you and others get together for work or play, form or join a team of war savers whose purpose will be to get folks all working together on this big idea of thrift (systematic saving) to win the war. The Government calls these teams War Savings Societies and is counting on them for real service.

Just think of it—25 members of a War Savings Society, by each buying four Thrift Stamps a week, can in six months supply a whole company of soldiers with steel helmets.

Also, this team idea sets new and patriotic standards of living. It becomes the popular thing to do with less; to make what we have do a little longer.

By buying only the needful things we give the Government a better market wherein to purchase things for soldiers.

Join or start a team of savers today. Sign a promise to spend wisely, save regularly and invest your savings in Thrift or War Savings Stamps. Talk over new ways to save. Get your friends into the game—sign them up for the team.

It's not the individual
Or the army as a whole,
But the everlasting team work
Of every bloomin' soul.—*Kipling.*

Increased Coal Output by Stripping

By A. C. VICARY
Erie, Penn.

SYNOPSIS — *Wherever the stripping method of producing coal can be employed it should be used, as it effects a 75 per cent. saving in labor per ton. Contrary to popular belief, small steam shovels will handle overburden at practically the same cost per cubic yard as the large special machines.*

ANY coal operator knows a great deal more about actually mining coal than I do. Before making even the most modest suggestion relating to underground mining, I would make doubly sure of my premises, and even then go very slowly. But I don't feel so much hesitancy in talking about strip-pit operation. It is a well-established fact that there are hundreds of coal-mine owners who do not fully appreciate what can be done by applying the methods of the "dirt-mover" to mining coal.

So we will look at the possibilities of coal stripping from the dirt-mover's standpoint—keeping in mind that the dirt-mover does not know everything about coal stripping, by any means. The experience of men raised from the cradle to coal mining is always a good thing to have when stripping. Here is one sad case of the lack of such experience by way of example:

Two young men happened to observe a wagon mine, which was located on the side of a hill near a peaceful little town in western Pennsylvania. The little mine was giving employment to a mere handful of workers, and the tonnage was small, less than 100 tons a day.

Forget to Consider the Coal

These two young men were old in dirt-moving experience, and they saw a fine chance for the application of steam shovel ideas to coal mining. So they told the operator of the little mine just what they thought of his methods, and how much better they could get out the fuel by stripping. Finally they secured a contract to excavate the coal, at a figure which was satisfactory to the coal man, and high enough to promise fat profits for them. They leased a shovel and brought it to the job. Everything went swimmingly.

About one month later the operation was at an end, and the two young men were dead broke. One of the would-be coal-stripping barons went to work for the man who had leased out the shovel, to repay the rental due. The savings of both men were gone.

Every detail had been carefully planned except the coal, which Mother Nature had unthinkingly left out of the hill. The two men had moved the steam shovel to the job and had made a fatal investment of their savings on the mere say-so of the inhabitants of the nearby town, who had confidently said: "Oh, that hill is just full of coal!" It would have cost them only about $25 to dig three or four test holes to verify this confidence of the natives. Three or four holes would have been sufficient to arouse their suspicions, as there was no coal in the hill except the little pocket which was being worked by the wagon mine and which would have "petered out" probably within a few months anyway.

I don't think any real coal operator would be likely to make such a mistake as that. He would know the tricks of coal beds, and he would have secured an accurate estimate of the quantity of coal present, its depth, and the thickness of overburden, before going ahead with stripping.

Most coal operators whom I have met are just about the exact opposite of those two young dirt-movers. They know pretty accurately what coal exists on their acreage, but they are too slow in starting to strip rather than too hasty. If every coal operator who really ought to start stripping (in justice to his own pocketbook and as a duty to the coal-hungry nation) should suddenly decide to do it, the manufacturers of steam shovels would be hopelessly behind in their orders for years to come.

There are literally hundreds of experienced coal operators who have idle coal on their acreage which could be stripped to excellent advantage. In most cases the total labor expense per ton on this coal would run about one-quarter of the labor cost per ton that is expended in mining the deeper coal on the same property. The operator has not attempted stripping, usually because of one or more of the following reasons:

1. He does not really believe the statements he has heard about the low cost of moving dirt and rock by steam shovel. Deep down in his heart he is scared by the amount of overburden to be handled—a yardage which perhaps would merely induce a dirt-moving man to take out his pencil and start figuring.

2. Possibly there is not a great quantity of coal near the surface, and the operator concludes that there is not enough strip coal to bother with—forgetting that coal mined by stripping is usually produced with a much larger margin of profit, and is consequently

LOADING THE STRIPPED COAL
Erie shovel owned by Cochran Bros., stripping and loading for the Youghiogheny Coal and Coke Co., Dawson, Penn.

equivalent financially to several times the tonnage of coal that lies deeper. And that's what he is really looking for, after all—the profits.

3. In many cases I have found that the coal operator has been frightened by accounts of enormous stripping operations, and has come to think of coal-stripping equipment as being represented by six figures. For instance, he is alarmed by visions of an enormous steam shovel costing about $200,000. Now, as matter of fact, steam shovels are available, as well as other equipment, to fit stripping operations of any size. Some coal operators are uncovering 200 to 300 tons of coal a day with a total plant investment of about $10,000, and are enjoying the most handsome profits they have ever made from coal. And it is a remarkable fact that on these smaller operations the cost per ton is almost as low as it is when stripping with an immense shovel.

I note that some coal men have received the mistaken impression that a large steam shovel will strip coal at a much lower unit cost than is possible with a

ANOTHER VIEW OF ERIE SHOVEL LOADING OUT STRIPPED COAL

smaller shovel. In fact, one man who stands high in the councils of coal operators recently made the following remarks, among others, before an important gathering of coal brains:

"The size of the [stripping] proposition has a lot to do with it. With a large operation and a large acreage, you can buy expensive machinery, because your cost of machinery per ton of output will be very small; but in an operation of only a few acres, your actual cost of machinery is prohibitively high per ton."

Now, it does seem as if this might be true, but it isn't! The statement seems reasonable, and the man who made it may be pardoned for making a natural mistake—one which anyone except an experienced dirt-moving man would be likely to make.

This man quite possibly arrived at his faulty conclusion by timing one "swing" or cycle of a steam shovel from the cut to the dump and back; then dividing this time for one swing into the total time worked per day, to get the total number of dipperfuls, which he then multiplied by the capacity of the dipper. Very simple!

He overlooked a fact which is well known to steam-shovel men: that the cost of moving a steam shovel increases rapidly as the size of the shovel increases—

ERIE SHOVEL STRIPPING FOR THE ELSIE COAL CO. AT BRIDGEVILLE, PENN.

disproportionately so. At the very start, in getting the shovel to the work, a large machine must be shipped in parts and practically built on the job, while the small shovel comes from the factory on a railroad car and is ready for work a day or two after the arrival of the car.

The same comparison is forced upon the notice of the operator every time that the two shovels dig themselves out of work and have to move up for more. The large shovel loses disproportionately more time in moving up.

Another fact which should be borne in mind is that the depreciation of the large shovel must be figured as being much more rapid than that of a smaller shovel. The large shovel is a special machine that is adapted only for special conditions, and is useless for other work. At the conclusion of a stripping operation, the large shovel must be moved to the nearest heavy stripping location, no matter how distant or at whatever cost. The owner must either move the shovel to where it can be used or lose the capital invested in it.

The small shovel, on the other hand, can be sold practically anywhere, because such shovels are used by excavating and building contractors, brick yards, cement mills, crushed-stone producers, sand and gravel producers, etc., and have a ready market. If a small shovel receives the right kind of treatment, it can safely be depreciated slowly. The capital does not shrink to any great extent. To prove this for your own satisfaction, just try to buy, say, a ¾-yd. Erie shovel second-hand. You will find it impossible to procure one for less than 80 per cent. of the cost of a new machine!

These are some of the points in favor of the smaller shovel, but I do not for a moment want anyone to get the impression that I am arguing for the small steam shovel and against the large one. Each has its distinct field and neither can compete with the other. Each machine does work that the other could not do. I merely wish to emphasize the fact that the obvious advantages of the large shovel are just about counterbalanced by advantages of the small one, with the result that, strange as it may seem, the small machine will move 600 or 700 cu.yd. of earth per day at about the same cost per yard as the 3000 or 4000 cu.yd. moved by a monster shovel.

Getting back to the discussion of the coal operator's natural hesitancy about embarking on a stripping proposition, I admit that it is perfectly natural for the operator to be most inclined to follow the kind of mining that he knows best, and that he should be somewhat more cautious in starting a method of mining with

which he is not familiar. One coal man said to me: "I am making enough money now; why should I spoil my sleep by trying to make more? If anybody comes along and makes me a good proposition, I will let him strip on my acreage, but I won't undertake it myself."

Most mining men are more ambitious than that, especially since it has been demonstrated clearly just what kind of a fix the nation is in, and is going to be in, for coal.

There is no more difficulty about running a stripping operation in connection with underground mining than there is in managing an old mine and opening up a new one at the same time. In fact there is likely to be much less difficulty in operating the strip mine. There are some miners whose ambition nowadays seems to be to get a barrel of beer and lie under a tree—and go back to work only when the bank-roll is gone. But labor problems are hardly problems at all when you are stripping. The labor force is small, and you can afford to select high-grade responsible employees and pay them well. If you pay a good steam-shovel operator 50 per cent. more than the market rate for his labor, the effect may quite possibly be to lower your per-ton cost. In any event, the one-man pay-roll increase is sure to be insignificant when divided by the total tonnage. But it would be a different matter to raise the per-ton rate to miners to 150 per cent. of the prevailing rate.

In order to give some idea of what can be accomplished on a small stripping operation with a 20-ton shovel, carrying a ¾-cu.yd. dipper, I submit some figures that have been taken more or less at random. These estimates are too general to be of value in any particular case, still they are based upon actual averages and may be depended upon as conservative.

With a 3-ft. coal bed, underlying 12 ft. of overburden, the 20-ton shovel will uncover from 125 to 150 tons of coal per day. With a 4-ft. bed, under 10 ft. of overburden, the shovel will uncover from 175 to 200 tons a day. With a 6-ft. vein, and 8 ft. of overburden, the shovel will uncover 350 to 400 tons per day. Working on a 9-ft. coal bed, underlying 10 ft. of overburden, the shovel will uncover 450 tons of coal or more.

These figures are for a box cut, and are of course less favorable than the records which the shovel can make if digging into the side of a hill, and casting down the slope at the side. The estimates of the tonnage uncovered are based upon the shovel moving 600 cu.yd. of overburden a day, which is a conservative figure often considerably exceeded. With favorable conditions it would do better.

Of course, the foregoing figures can give only an approximate idea of the probable output. No real estimate can be made without considering the specific conditions which govern each particular case. The estimated cost of the shovel for a day's work will be about as follows:

Interest on shovel at 6 per cent., plus a depreciation of 20 per cent. (Note: As explained above, 20 per cent. depreciation is much greater than the actual loss of value. If you set apart even 10 per cent. to depreciate a good small shovel, and then take reasonable care of it, the shovel will in five years be valued on your books far below its actual market worth.)	$ 8.75
20 per cent. depreciation and 6 per cent. interest on cars, track, etc.	2.60
Shovel runner's wages per day	8.00
Wages of fireman and pitman at $4.50 per day each	9.00
Wages of handy man, for water and coal supplies	4.50
Incidental supplies per day	1.00
Total	$33.85

Now divide this figure, the cost of a day's operation of the shovel, by 200 tons, if that is the amount of coal uncovered, and the cost of stripping the coal by steam shovel is approximately $0.17 a ton. In case conditions were so favorable that 400 tons of coal per day could be uncovered with one ¾-yd. shovel, the cost per ton for stripping would be about $0.085 a ton.

This does not include the cost of loading the coal, which a shovel will do for about 15c. per ton, or perhaps less, in either case. This gives a total cost of 32c. a ton for stripping the coal and loading it on the cars, when 200 tons per day are uncovered; or 24c. a ton for stripping and loading, when 400 tons are uncovered. To this must be added at the start the cost of hauling away earth to begin the operation.

These are figures based upon actual work, and may be relied upon. In adding the wages of management to these costs, it is justifiable to estimate not more than the unit charge for management in deep-seam mining; and this charge should, if anything, be still less after the operator is reasonably experienced in stripping work.

It is not necessary for me to comment on the comparison that the coal operator will involuntarily make between the cost per ton when stripping and loading by steam shovel, and what it is costing him to produce coal by deep-mining methods. Under present conditions, the moral is almost too obvious to recite. With the nation's double shortage (of coal and of labor) it is a patriotic duty for the coal-mine operator to strip coal, if he has any that can advantageously be produced by this method. It is a clear case of getting three times the tonnage per man employed—or better. If there are stripping possibilities on your property, now is the time that they ought to be realized.

SHOWS THE PORTABILITY OF THE SHOVEL
A 20-ton Erie shovel climbing up the side of a mountain, along the bed of a creek, to get to the coal-stripping operation of the Elkhorn-Piney Coal Mining Co., Powellton, W. Va.

In closing, I wish to make it clear that this article is not interested testimony, designed to promote the sale of steam shovels. Nowadays the manufacturer of steam shovels has a great deal more trouble building them than selling them. If these few remarks should lead anyone to investigate and finally buy a steam shovel, he will probably find that it will be necessary for the shovel manufacturer to divert a machine from some less essential industry, and sell it to him in preference because of the vital importance of *more coal* at this time, when the country is already facing a shortage.

Maximum Production for Humanity's Sake

By H. K. PORTER
New York City

SYNOPSIS—*Maximum production is necessary during the present war, but this is unobtainable unless efficient apparatus is provided. Locomotive haulage, both trolley and storage battery, has done much to increase coal production. Easy running cars would doubtless do vastly more.*

IT HAS been aptly said that the titanic conflict now being waged across the water is no longer a struggle of the people of a number of nations against the people of a number of other nations, but rather it is a struggle of nations against nations—the struggle of the allied nations, with their liberal democratic governments, against the corrupt military rulers of our enemies.

Of the ultimate victory of the Allies and the vindication of the principles for which they are fighting there is little doubt in the minds of clear-thinking men, and the vast preparations which are being made by our country go to further insure the complete success of the allied cause and the ultimate victory of humanity.

All industry in the United States must bend its every endeavor toward producing the greatest volume of materials, both raw and finished, with the greatest possible economy and efficiency.

It is not possible that maximum production for humanity's sake will be realized in every instance, but to insure maximum output in all of our industries it is necessary that there be a closer coöperation between employer and employee. This desired harmony of effort can only be realized through a closer understanding of the problems of the employees, the men at the lathes, in the mines, at their work—wherever they happen to be.

Workers Now Better Understood

In many of our industrial establishments the laboring man has become better understood through the medium of welfare work and kindred activities than in the years gone by, and his standard as a working man—as a producer—has been raised by a goodly percentage. Many of the foreign-born have had instilled into them the love for our country and its ideals, and they have come to love the industry in which they are working.

It can be admitted, however, by those of us who are familiar with conditions in and about the mining operations, that many operators have failed to realize that through a study of their miners, by helping them to raise their standard of living, by more acutely realizing their thoughts, aims and ideals, more efficient and more willing work would be performed by the foreign-born miners, who through birth are temperamentally different from us in almost every way.

My sentiments were accurately expressed by an editorial in *Coal Age* which said: "It may be that the foreigner is the man of the stricken barn, the blighted field and the crippled horse, but no good will come of reminding him of his misfortune. In the language of the streets, 'have a heart.' What a foreigner wants more than your praise of America or your denunciation of his Fatherland or Motherland is the grip of your hand, the tremor of your voice and the exultation of service which your patriotism evokes."

The coal-mining industry should adopt this as its motto and as its guide, because in it lies the possibility of maximum production for humanity's sake.

Most of us will admit that we can instill the desire to work from patriotic motives in the majority of our foreign-born miners. And if through a clearer understanding of their aims and ideals we can accomplish our avowed purpose, it then becomes necessary to give them the proper tools to work with the economical tools, to remove as much of the drudgery from their toil as we possibly can. No man is a willing worker if his energy is taxed to the limit, if his energies are drained to such an extent that when he arises in the morning the exhaustion of the previous day has not been removed by a night of rest.

Progress Made by Introducing Machinery

We know that coal-cutting machinery has been responsible for increased production, because it enables the men to do their work faster and in a pleasanter manner, and because it permits them to earn more per day.

We know that the electrification of the main haulage provides a better supply of empty cars for the miner and has helped to increase production greatly. The use of storage-battery locomotives for gathering purposes also has, and is, and will have, a tremendous effect toward a more willing and more economical production of coal.

The elimination of the mule for gathering service was a humane step, both for the mule and for the men working in the mines. It has undoubtedly worked toward a greater production.

Almost any mining man who has studied mine labor problems will tell you that more grumbling, discontent and layoffs have developed through the dislike of handling cars than from probably any other cause originating within the mines. Of course, paid disturbers have hatched up and magnified imaginary troubles, in many instances, which have also upset the routine of coal production. But the handling of mine cars by the miners has always been a source of annoyance and friction.

Imagine yourself struggling with a stiff-running mine car, trying to push it over irregular tracks or a wooden emergency track. Could you within three-quarters of an hour afterward devote yourself to your work with your best energy? How many of your men have ever been laid up for two or three days by a sprained back? Your company doctor can cite numerous instances where a disabled miner has attributed his injury to attempting to move a stiff-running mine car. It is positively back-breaking.

Most of the people who have a knowledge of coal mining and who are actually engaged in the production of coal will say positively that their cars are placed for the miners under all circumstances. They will assert

that cars are rarely, if ever, handled manually; but in many instances, and in fact in the majority of cases, they are considering ideal and not actual conditions. Little as they want to believe it, thousands and tens of thousands of loaded and empty mine cars are moved by the labor which should be loading coal, every day that our mines are working.

The miner and his "buddy" must push the loaded car to the parting and push the empty car back into the room. The men must move the stiff-running mine cars at the shaft bottom and they must push them on the tipple. Every second's delay in the handling of one mine car, when multiplied by one thousand or by ten thousand, means an enormous waste of time throughout a complete working day.

It would not be so bad if one man could handle the ordinary stiff-running car, but now that mine cars are getting larger in size, so that they hold from 4 to 5½ tons of coal, they are heavy to handle and in many instances it takes three or four men (we have heard of instances where it took five men) to push some of the heavy mine cars. If you figure the time of the extra men needed, you cannot but realize that increased production for humanity's sake is being seriously crippled by the lack of proper cars in which to haul the coal.

In one of the accompanying photographs three men are seen pushing a loaded mine car. This car weighed about 4¼ tons and was equipped with ordinary plain bearings—back-breakers. In the other photograph is shown a car of the same weight, which is being pushed by one man—and this man was able to start the car from rest without assistance and propel it with ease.

The track where the photographs were taken was approximately level, and while it might take two men to push the roller-bearing car up a slight incline, it certainly would have taken four or five men to push the plain-bearing loaded car up the same slope. The advantages of the antifriction bearing are especially potent in the anthracite region, where storage-battery locomotives for gathering are not as numerous as in the bituminous section, and where a severe shortage of mules exists at the present time.

This means that in the anthracite region a great many more cars must be pushed by hand this year than last year. The same is true beyond the question of a doubt in connection with a great many of the bituminous mines, of which we have no definite record.

The photographs which are here shown were taken before an assemblage of about 30 prominent mining men and was sufficient proof to them of the desirability of using roller-bearing mine cars. These are easy on the men, as compared to the plain-bearing cars which make the labor of pushing extremely tiresome.

Then again, roller-bearing mine cars need to be lubricated but once every three or four months as compared to the every-day lubrication of those with plain bearings. In fact, a prominent operator of western Pennsylvania recently stated that the proper time to oil a plain-bearing mine-car wheel is every time you look at it, because every time you look at it it needs to be oiled. Consequently, the labor involved in oiling the plain-bearing car is wasted, because if roller-bearing mine cars are utilized the services of the oiler can be employed in a more profitable manner. In other words, the use of roller bearings releases another man for work in the actual loading of coal.

THREE MEN NEEDED TO PUSH A LOADED MINE CAR EQUIPPED WITH ORDINARY PLAIN BEARINGS. THE SAME LOAD, IN A MINE CAR WITH ROLLER BEARINGS, WAS PUSHED WITH EASE BY ONE MAN

It seems rather far-fetched to speak of roller-bearing mine cars and maximum production for humanity's sake in the same breath, but the operators who are using roller-bearing cars know that the two are synonymous. Many of them will tell you that their miners fight for the easy-running mine cars. They well know that if they secure the easily pushed car their work is going to be lessened. They will then not be compelled to break their backs attempting to produce the coal which is going to win the war for us and our allies, and which is going to help the miners to become better citizens. Simultaneously, the coal operators through an increased production will be enabled to expend greater efforts in making true-blue Americans out of the nomadic foreigners that now produce the Nation's fuel.

Only when combustion is very poor, owing to inadequate space above the fuel bed and rapid cooling of the gases, are hydrocarbons likely to be found in flue gas.—*Bureau of Mines Bulletin No. 135.*

Reliable Gears

By C. J. BROWN
Pittsburgh, Penn.

SYNOPSIS—*A maximum production of fuel is highly necessary at this time. All elements of the equipment upon which the production of coal depends should be selected with care. Gears, in order to be reliable in use, should be both hard and tough. These qualities are brought to a maximum by heat treating the steel of which the gear is made.*

CONTINUOUS operation in any essential activity is demanded and absolutely necessary at this time. The needs of our Government make this imperative; especially is this true in the coal-mining field. To produce the coal necessary every sinew must be stretched to the breaking point; every feature of operation must be carefully studied and acted upon in order to eliminate curtailment of output; there must not be any delays due to breakages or other avoidable causes; mines must produce their maximum tonnage continuously.

Gearing represents an important item in the chain of equipment, the parts and supplies of which, when linked together, go far toward making continuous operation possible; and too much attention cannot be given to its selection and care. This is not only true insofar as locomotives are concerned, where much time is required to replace broken gears or pinions, resulting in serious delays to haulage systems and consequent loss of time spent by mechanical men in making repairs, who might be otherwise engaged, but it is also true of all other gearing that is used in and about mining operations.

Case Hardening Not Ideal Treatment

So far as gearing is concerned, the delays illustrated can only be successfully avoided by using a superior grade of material. This is a practice that the R. D. Nuttall Co. has been endeavoring to have the mine operators follow, and with a considerable measure of success. This company has advocated heat-treated gearing for mine service for a number of years, correctly claiming that it is false economy to use anything else.

Case hardening was the first step, but although it proved to be quite a success as compared with untreated gearing, it was not the ideal treatment for mine service because the glass-hard surface with soft core or center, while it was ideal from the viewpoint of wear alone, did not have the necessary toughness to withstand the severe shocks and stresses to which mine gearing of all descriptions is continually subjected. Consequently, earnest and extensive research and experimental work were carried on by this firm to perfect a treatment better adapted to mine conditions.

There are two important points to be considered by the mine operator when deciding upon the type of gearing best suited to his purpose, especially when his locomotive gearing is the issue. These are hardness and toughness. One is just as important as the other. It is not wise to select a gear or pinion with great surface hardness and soft core, capable of giving long service if steady and continual wear were the only consideration, but unable to withstand breakage due to the many stresses and shocks incidental to mine service. Neither should there be selected gearing tough to the point of successfully eliminating breakage caused by frequent starting and stopping, inexperienced motormen, uneven and crooked haulage roads, etc., but without necessary surface hardness to give long service from the viewpoint of wear.

Hardness and Toughness Ideal Combination

The ideal is a combination of the two good qualities, hardness and toughness, and this combination unquestionably has been obtained in specially heat-treated gearing; in fact, the principle of the treatment has been solely founded upon these two qualities. The treatment referred to is well known to the larger number of mine operators and is fast becoming the standard—namely, Nuttall BP grade when applied to forged steel and NP grade when applied to cast steel.

To better appreciate the benefits to be derived from the installation of treated gearing—gearing that will show results at the end of the year—the following record should be carefully noted:

A Westinghouse electric mine locomotive No. 38581, equipped with 35-hp. motor, operating over a 5000-ft. haulage road with two maximum grades of 2½ per cent., around 75 deg. curves, and hauling full trips up grade, covered 4000 miles, and hauled 100,000 tons of coal per year. A BP grade pinion in this service gave 100 per cent. results for a period of five years and was not entirely worn out when removed. It hauled during this period 500,000 tons of coal under heavy service conditions. In this same service an oil-treated pinion wore out in six months; it hauled 50,000 tons of coal. In five years ten oil-treated pinions would have been necessary, resulting in ten interruptions of service. Allowing one-half day for each interruption, this would mean a reduction in output of 3000 tons. A case-hardened pinion broke in 1½ years; it hauled 150,000 tons of coal; but the vital point is that it broke. The broken teeth wedged in the gear and locked the wheels. Not only was the locomotive disabled, but the haulage

TABLE OF COMPARATIVE DATA

Grade	Material	Carbon	Ultimate Strength	Elastic Limit	Elongation in 2 In.	Reduction of Area	Surface Hardness Brinell	Relative Life	Relative Cost
CS	Cast steel (Untreated)	Medium	60,000 to 75,000	30,000 to 40,000	18–22%	25–35%	121–155	$1.00	$1.00
BP	Forged steel	Medium	115,000 to 130,000	80,000 to 90,000	8–12%	25–35%	418–555	4.00	1.30
NP	Cast steel	Medium	110,000 to 120,000	75,000 to 85,000	6–10%	20–25%	360–512	3.00	1.20

road was blocked for two hours, which alone meant a reduction of nearly one-half day in production. It will not be necessary to go into detail with the mine operator to illustrate the saving in ultimate cost effected by having in service the type of pinion whose performance is first cited.

The table of comparative data, shown on the preceding page, gives interesting and valuable detail information for anyone interested in the subject of gears and gearing.

It will be noted that the tensile strength of the BP and NP gear from the test piece is not in proportion to the tensile strength corresponding to the Brinell hardness. This is due to the test piece being a measure of the physical properties at the center of the tooth, while the Brinell test gives physical properties of the gear at the surface of the tooth. The equivalent tensile strength as shown by the Brinell tests of the two grades is as follows:

Grade	Brinell Hardness	Equivalent Tensile Strength
NP	360–512	178,000 to 253,000
BP	418–555	204,100 to 273,300

It can readily be seen that the great resistance to fracture of these grades is due to this high strength of the outer fibers of the steel. This hardness grades off very gradually in a straight line ratio to the center of the tooth.

Erico Portable Bonding and Welding Apparatus

By W. E. Huber
Cleveland, Ohio

The electrical distribution of energy and its attendant losses is one phase of the momentous problem of coal. The heavy current flow of the electric railway where the track rails serve as part of the circuit may be a source of loss against which conservation tactics may well be employed. Better maintenance of track than has obtained in the past cannot be expected, therefore the return circuit of the electric railway is a field of increasing interest, for progress in method and appliance.

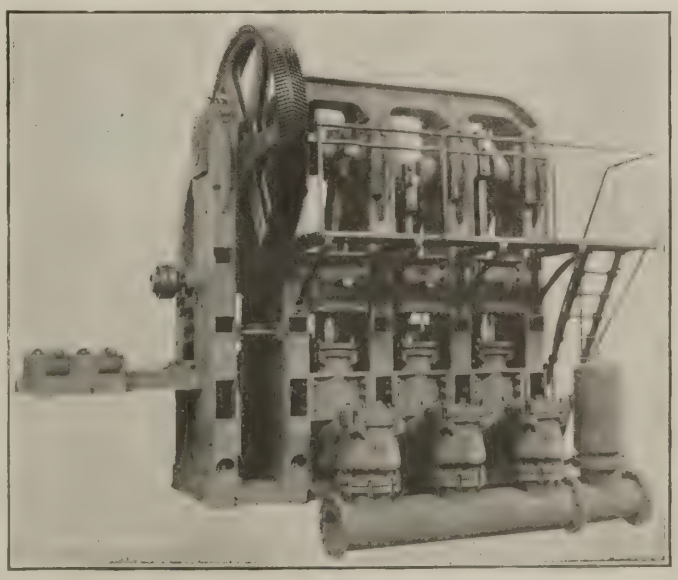
The old method of applying a welded copper bond to a rail joint made use of a bonding car which carried a pair of resistance welding clamps with a suitable motor-generator and low-voltage transformer. In the early days of electric traction when the problem was the bonding of new track, the bonding car left little to be desired, and under the maintenance conditions of some roads it still meets all of the requirements that have developed. It is a work car as well as a first-class bonding apparatus.

The problem of a small portable apparatus which would comprise all of the welding functions of the bonding car was studied from the beginning; constant effort and the aid of developments along other lines has brought the solution in the Erico portable welding apparatus, which weighs about 200 pounds. It comprises in its functions all those of the three-ton bonding car and in addition, when it is not in use for installing bonds, it may be transformed into an arc welding set for work either in shop or along track. The complete apparatus for rail bonding on a 600-volt line consists of a welder, a rheostat and a grinder for cleaning the rail. Fig. 1 shows the apparatus adapted for a 250-volt line, in which case the rheostat, having a lesser demand for radiating capacity, is quite small and is transported as a hand tool weighing about 25 pounds. The evolution from bonding car to portable welding apparatus for a 250-volt line thus brings the total weight of apparatus from three tons to a trifle over 100 pounds Fig. 2 shows the 250-volt rheostat as an arc welding set.

FIG. 1. WELDING A RAIL WITH THE ELECTRIC WELDER

FIG. 2. MAKING REPAIRS IN THE SHOP

The original bonding car makes use of heat generated by the flow of a heavy, low-voltage current across the terminal of the bond, at right angles to the rail; the carbon electrode of the welding clamp presses the bond terminal against the rail until the heat generated by the current from the transformer effects the welded union of bond terminal and rail. The portable welder also presses the bond terminal against the rail by means of an electrode and, in so far as the heat action and welding of the terminal is concerned, is similar in its action to the bonding car; the full intensity of heat and consequently the completed operation is obtained more quickly with the portable apparatus than with the car. The electrode of the portable welder which engages the bond terminal is not the solid carbon block used with the bonding-car type of electric welding apparatus, but consists of a hollow composite box with a graphite contact against the bond terminal; within this small chamber the heat is generated at the terrific intensity of the arc, to be conducted through the thickness of the graphite plate and diffused by the graphite medium into an ideal, uniformly incandescent welding electrode at the contact with the bond. The heating medium of the portable welder is a form of inclosed magnetic arc, the negative electrode of which is the graphite plate which contacts with the bond terminal. The remarkable part of the apparatus is the effect of the magnetic field within which the arc is drawn. The effect of the field upon the arc flames may be likened to that of an air blast applied to a gas flame, the analogy holding as to the increased quantity and intensity of heat, due to a higher voltage drop, and as to the vigor of the action, which is accompanied by an explosive vibrating sound. The magnetic field of the welder is the result of the rectangular solenoid which forms the body of the welder, the axis of which is the center line of the arc.



The welder is supported in operating position at two points on one rail and by a chain and hook reaching over to the other rail. To disengage the apparatus, merely pick it up. Adjustment of the contact between the negative electrode and the bond terminal is obtained by varying the length of the chain, which changes the inclination of the apparatus, and by the hand wheel which raises or lowers the body of the welder. For a given rail these adjustments need not be changed. Pressure of the electrode or front plate of the furnace box is secured by a pressure screw.

The inclosed magnetic arc of the portable welder has a drop of about 125 volts and requires about 100 amp. when in normal operation. An open arc pencil has a drop of from 20 to 50 volts. In case of operating either the welder as in Fig. 1 or the open arc pencil as in Fig. 2, the rheostat is interposed between the operation and the trolley wire. The rheostat comprises a number of unit resistance paths, each of a common current capacity under the same potential source. The operator of the welder may therefore at all times secure the most efficient amperage for his apparatus regardless of any drop in the line voltage, by adding to the number of current paths of the rheostat in operation; likewise the arc welder may keep his current up. The current capacity of the rheostat is thus increased until all of the current paths are in operation. The apparatus as a whole is one of the most timely improvements to assist in meeting the great maintenance difficulties of the present time. The bonding feature of the apparatus alone gives it a prominent place in the list of up-to-date appliances, while the arc welding feature is coming more and more to be first thought with the emergency man.

Modern Mine Pump

The accompanying illustration shows a recent development of the vertical triplex plunger pump for mine use. Mine water, as a general rule, is acidulous and calls for a pump the cast iron of which is protected. The water end of this Scranton mine pump is lined with wood, lead and bronze, so that not one square inch of cast iron is exposed to the action of the water.

A mine pump to be serviceable must be simple, yet rugged in construction. It must be sectionalized as far as possible and all parts be readily accessible. The pump shown has a five-bearing crankshaft with adjustable wedges located on the top half of the bearing. Since on a single-acting pump the thrust is on the top half of the journal box, any necessary adjustment can be readily made without throwing the crankshaft out of alignment. The crank- and wristpin brasses and

A WOOD LINED TRIPLEX PUMP

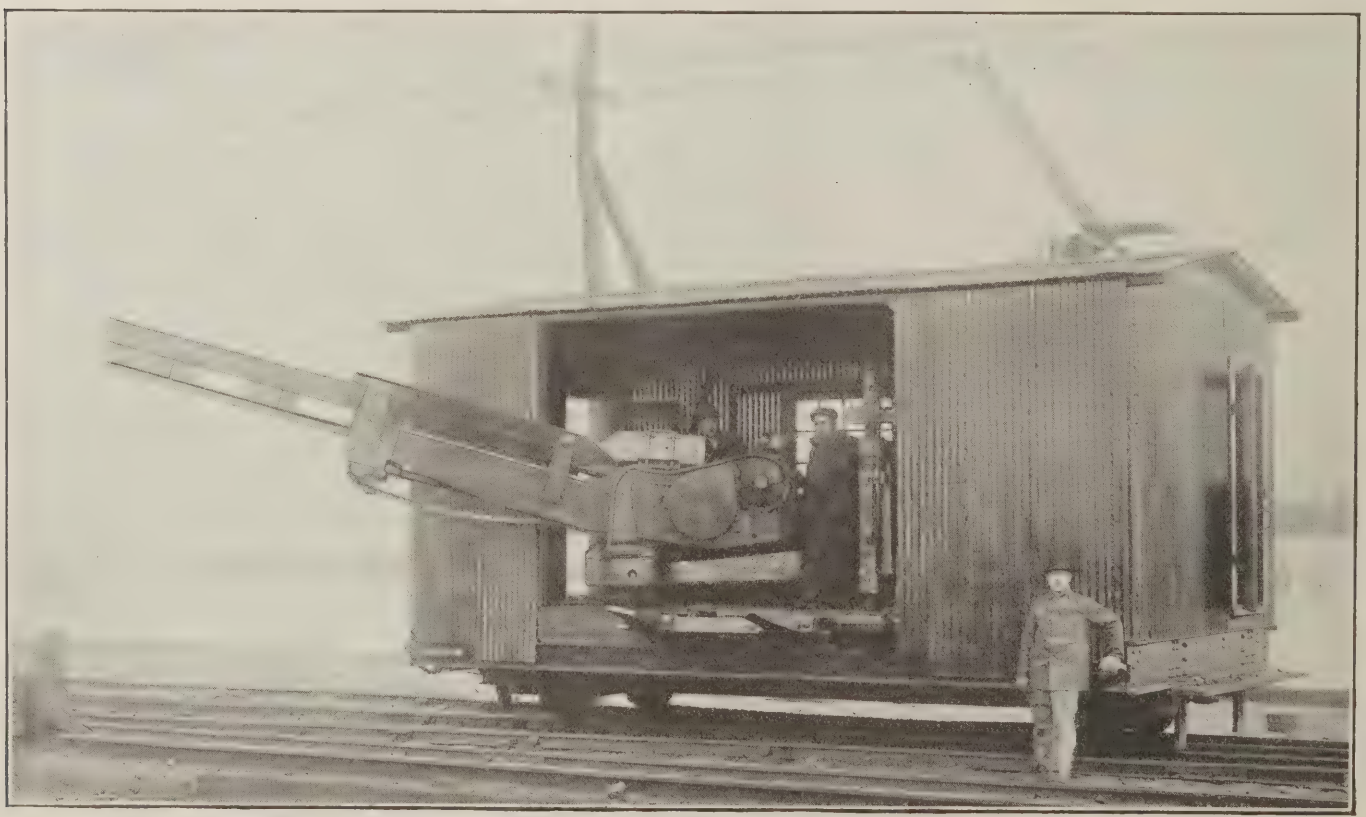
crosshead shoes are made of a special bearing bronze and provided with adjustment for taking up wear.

Pumps of this type are usually driven by single-reduction herringbone gears and direct-connected by flexible coupling to the motor. The water valves, which are the most important part of a mine pump, must be especially designed for each individual case. The water velocity is held down to 3 ft. per second, which insures a quiet-operating and long-lasting valve.

The valve seats are of the double-ported type and flanged, facilitating easy removal for refacing. This is essential, as the water handled by most mine pumps is gritty and the faces of the seats become scored. The valves up to 600 ft. vertical lift are made of rubber and inserted in a bronze plate which extends down and around the periphery of the valve, holding it rigidly in place. Rivets, studs or tap bolts should not be used to hold a rubber valve to its plate, as they are quickly affected by the acid water and result in considerable trouble.

The valve stem and spring are of phosphor bronze. The spring is incased in a bronze cage, as a protection against the scouring action of the water. The valves, seats, chambers, and all parts where possible, are made interchangeable to eliminate the necessity of carrying a large stock of repairs.

Mine pumps and their driving motors should in all cases be mounted on heavy cast-iron baseplates, securely tied together. This arrangement facilitates the erection of the pump and guarantees a permanent installation. Triplex pumps of the foregoing design have developed an efficiency of 85 per cent. for the pump alone.



Box-Car Loader in the Present Emergency

By ELLIS B. USHER
Milwaukee, Wis.

THE Government's warning that 75,000,000 to 78,000,000 tons more coal will be needed in war industries this season than last, and that this amount must be had by increased output or drastic curtailment in nonessential industries and domestic uses, leaves no chance to escape the conclusion that, with known labor shortage, steadily growing worse, all the mechanical aid available to mining must be utilized. Machines that will increase production at the mines, that will handle and move the product more expeditiously and at the same time economize labor, must be put to work.

Machines of proved efficiency naturally should be the first to be chosen. The mechanical box-car loader built by the Manierre Engineering and Machinery Co., of Milwaukee, Wis., although one of the newer loaders for coal and coke, has during its nine years' career taken a place that justifies calling attention to it as an instrument that may greatly assist in winning the war. The Manierre loader was the first machine to load coal, coke and other bulk material into box-cars on the conveyor principle without throwing it, and therefore practically without breakage.

All the different types of this loader are built on the same principle, and consist of a conveyor frame

MANIERRE LOADER, FOR LOADING COAL, COKE AND OTHER BULK MATERIAL INTO BOX-CARS

carrying the motor and conveyor balanced in a fork supported on the end of a box-section, cast-steel arm, which is journaled on another similar arm, in turn carried by brackets upon a post. This post is securely attached to a monolithic foundation or other adequate support. The arms are journaled on ball and roller bearings and move with great freedom. The loader can thus be placed in the car with great facility since it is without complicated mechanism. The balanced feature of the conveyor frame makes it easy for the operator to tip the conveyor to the floor when starting to load, thus avoiding throwing and breakage. This is accomplished by a worm gear at the rear end of the machine.

The chutes, which are of several varieties to meet different conditions of installation, have the common characteristic of a universal motion at the delivery end, where attachment is made to the loader. This enables the chute to follow the loader, in all positions, as the coal is distributed throughout the length of the car.

Any of these loaders (there are seven standard types) can be built stationary or portable. They all will load box-cars on either side, on two tracks, or the machine may be placed on the opposite side of the car from that on which the chute enters. Special conditions are easily met by construction adapted to them.

Space does not permit more detailed analysis of the mechanical construction of this machine or the many engineering problems that it has successfully solved, but results accomplished are vital at this time and testimony to such accomplishments is easily to be had.

One of the leading dock companies of the Great Lakes says: "One man operating this loader in box-cars takes the place of four men trimming by hand and does the same work in one-fifteenth of the time that the four men will do it. With this loader we frequently load run-of-pile bituminous coal at the rate of one car every five minutes or twelve cars in an hour, while it is good work for four trimmers to load a 40-ton car in one hour and 15 minutes."

A large byproduct coke shipper gives testimony as follows: "The cost of loading per ton on a type 'C,' 16-in. machine is $0.0235, and on the 24-in. machine $0.03. At the same labor rates the cost of loading box-cars by hand would be approximately 23c. per ton."

A large mine owner in Illinois, who has just put in a machine at a second mine, tells the manufacturers that the first loader "took the place of six men loading by hand and in addition increased the number of box-cars loaded 400 per cent. in eight hours' work."

From coal mines and large dealers in all the fields in this country and Canada comes the cry of distress as to labor and car shortage. Nothing therefore is more important to the Government and to the public than to utilize every successful and proved mechanical device available. The Manierre loader is in this class, and the manufacturers looking farther ahead than many other concerns have prepared with a supply of standard machines and motors on hand. This has been done in order to meet rush orders with a promptitude that will in itself be a public service.

Safety Powder Flasks and Fire Pails

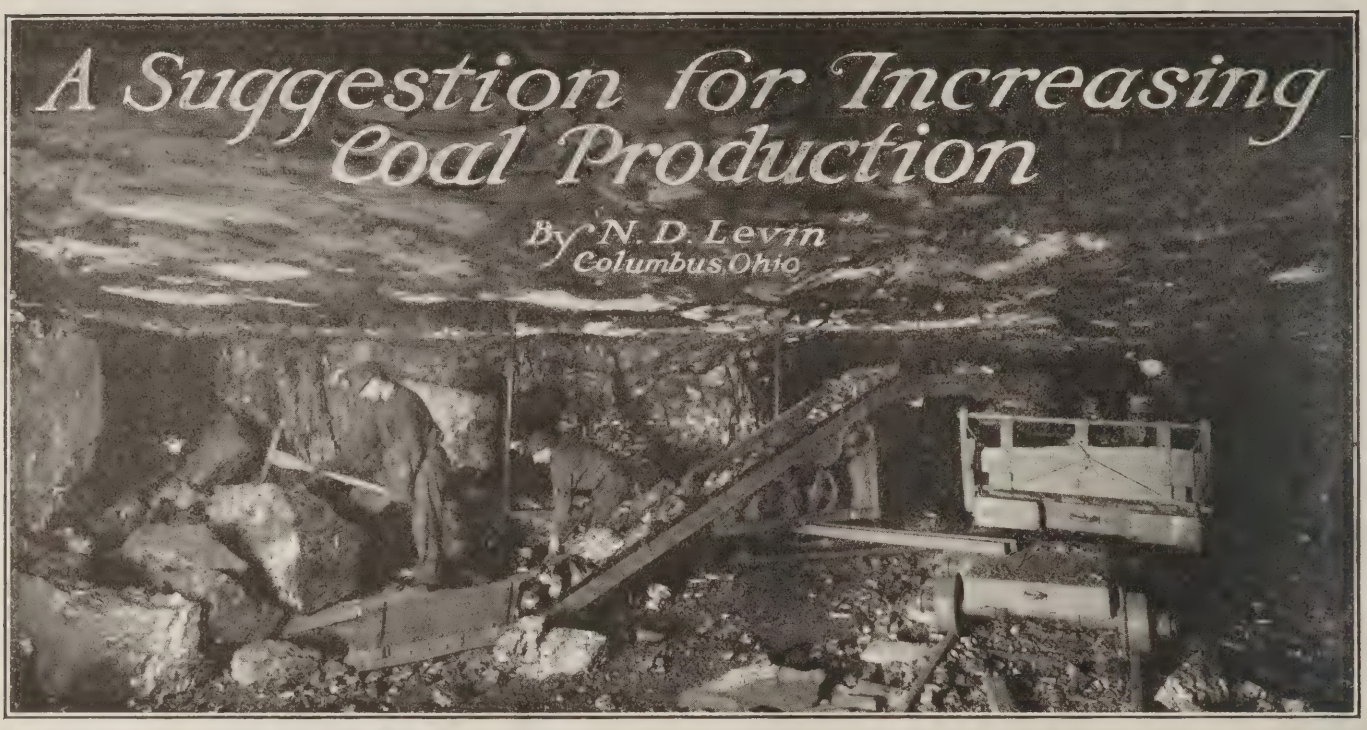
A consideration of great interest to those engaged in coal production is the large number of men employed in the industry that are subject to draft. The number amounts to roughly one-sixth of all the men employed. The labor supply is limited, and the gap made in the ranks of the coal miners by the needs of the army can be filled, if at all, only with great difficulty. Under such circumstances the questions of labor efficiency and conservation become even more important than in normal times.

As a result even greater care than ever should be exercised in accident prevention, and only such equipment should be employed as has demonstrated its econ-

SAFETY POWDER FLASK

omy and durability. "Fibrotta" powder flasks or jacks as manufactured by Cordley & Hayes, of New York, come under this category.

These flasks are entirely non-metallic and are consequently non-conductors of electricity. An electrical conductor coming in contact with the exterior of the flask will thus have no effect upon the contents and will not cause an explosion. This safety feature has been recognized by many mine inspectors throughout the country.



These powder flasks are made in one piece under heavy hydraulic pressure. They are consequently seamless and jointless. The surface is so treated chemically as to make it hard and glasslike and impervious to moisture. The cork stopper is attached to the flash by means of a strong linen cord, thus preventing the loss of the cork.

Flasks of this kind are economical because of their long life, which exceeds that of many of the metal containers the price of which is high and still rising. It is claimed by the makers that Fibrotta flasks will not swell, rust, warp, leak or dent out of shape. The material of which they are constructed is hard and strong and will stand rough usage. In addition it is a non-conductor of heat as well as electricity. As a result of all this these flasks are light and easy to handle and will not sweat on the inside and injure the contents.

The manufacturers of these flasks also made funnels for filling them, as well as fire pails of the same material. Some of the latter have been in continuous use for many years without serious deterioration. Such pails are not affected by anti-freeze solutions and when properly labeled are approved by the Underwriters' Laboratories and recognized by all the fire insurance companies.

A Suggestion for Increasing Coal Production

By N. D. Levin
Columbus, Ohio

SYNOPSIS—*As the demand for coal grows stronger, the man power available for its production will doubtless become less. To offset this shortage various means have been proposed, but none appear to possess greater merit than the employment of light, easily portable loading conveyors, which perform the most arduous work the loader has to do. In practice these have made possible an increased production per man employed.*

AT THE present time the production of coal is limited by the ability of the railroads to handle the output of the mines. The time will come, however, when the transportation companies will have sufficient equipment and be in position to handle and distribute the coal produced. The question will then be, Will the mines be able to maintain, or rather increase, the tonnage? One or two more drafts will, in certain localities, reduce the man power to such an extent that its lack will be felt keenly.

The demand for coal next winter will be enormous; it is claimed that it requires 16,000 tons of coal to build an 8000-ton ship, and 80 lb. of coal to produce a single 3-in. shell. We must build hundreds of these ships and millions of shells. At the same time every effort should be made to keep the industries of normal times going so far as possible.

Several remedies have been suggested; for instance, to exempt miners from military duty. But this would hardly seem practicable, as there are many other industries—railroads, steel mills, iron mines, ship-building yards, etc.—that would have equally good reasons for claiming exemptions. It has also been suggested to allow boys to work with relatives in the coal mines; also to employ women for work underground. The general opinion is, however, that such means should not be resorted to except in case of extreme necessity, and we trust that the war will be won before it becomes necessary to send our women and children into the coal mines.

Another suggestion is to lengthen the working day from 8 to 10 hours. This would not give the desired result; England lengthened the working hours during the war without deriving any benefit therefrom. The object of this article is to make a suggestion that may be helpful.

Despite the fact that most modern coal mines are equipped with machinery especially adapted to undercutting and hauling a maximum output, and each operation necessary to obtain such output has been carefully studied and special machinery designed therefor, primitive methods of loading the coal still prevail to a large extent.

Efficient and reliable apparatus is available for undercutting the coal bed; holes for the insertion of the blasting charge are drilled either by the use of electric or compressed-air apparatus; explosives have been brought to a high state of perfection; electric gathering and haulage locomotives have practically replaced animal power, yet the coal is still almost universally shoveled into the mine cars by hand.

Experiments have been made during the last two

THE LOADER AT WORK

years with a small conveyor, such as shown in the accompanying illustrations. It has been found that two men will average 50 to 80 tons per shift using this loader. It is obvious that less labor is required to shovel the coal onto the end of the conveyor (which is only about 6 in. high) than to shovel it into a car 3 or 4 ft. in height. A second handling of the coal is unnecessary, as the conveyor can be so located in a room as to reach the far corners. Where the coal is not shot down onto the floor, a considerable quantity of it can be pulled down from the face in such a manner as to cause it to fall onto the conveyor. In certain instances an apron is used on each side of the conveyor. This is not shown in any of the illustrations. Coal falling upon this apron can be readily pushed into the conveyor.

In states where the shooting of the coal is performed during working hours, the conveyor can be set so that the coal is shot down onto its outer end and onto the aprons. The conveyor is so light that it can be handled and placed in position by one man if necessary. The truck is equipped with roller-bearing wheels, and can be pushed from one place to another by two men unless the grades are heavy.

My reason for recommending a light, inexpensive machine of this kind is that delays will not seriously affect the usefulness of the machine. It is evident that if the conveyor is compelled to remain idle, say 15 minutes, waiting for a car, the men will have work to do in the meantime; they may pull down coal from the face, or load up the front end and aprons so as to have a carload ready without any shoveling, as soon as an empty is secured; or they may take a rest, which under many circumstances can hardly be considered a waste of time.

A man shoveling coal into a car is desperately inefficient from the mechanical standpoint. In order to lift a shovelful of coal weighing, say 20 lb., through a distance of, say 3½ ft., he must lift his entire body through a certain distance while he raises his trunk (from the hips upward) from approximately a horizontal to a vertical position. The total muscular energy thus expended is large, while the portion of it consumed in useful work is small.

By the use of the conveyor it has been demonstrated that an increase in output can be secured, employing the same number of men. If the men can double the number of cars loaded per shift by the use of this machine, it is obvious that each place will be loaded out in one-half the time required by the use of shovels only, and therefore each place can be cut and loaded out twice as often. This is equivalent to doubling the output with the same number of loaders, or from the same territory the same output can be obtained with

THE LOADING MACHINE UPON ITS TRUCK READY TO BE MOVED

less men and no development work will be necessary for some time to come.

Conveyors of this kind can be quickly produced in large quantities, thus securing an early increase in tonnage, much earlier than could be secured by opening new territory. What the country needs is output, and for quickest results at comparatively small expense, I know of no way to equal the use of this small conveyor equipment.

It is easy to understand that two molecules of CO can find one molecule of oxygen in the furnace gases much more quickly than one molecule of soot can find 12 molecules of oxygen. Therefore, simple gases, like CO and H_2 burn quickly in the furnace, because they more readily find the small amount of oxygen needed for their combustion; whereas the more complex combustible like soot burns slowly.

Efficient Haulage Methods

By PAUL TEAS
Cleveland, Ohio

SYNOPSIS—*It is useless for the miners to dig coal unless it can be transported quickly and promptly to the tipple. Mine transportation is the "neck of the bottle" that must be kept open if coal is to be shipped. Gasoline-locomotive haulage is proving efficient for this purpose.*

EVERY new responsibility created by the war taps a new source of energy that the American people had scarcely dreamed of possessing. The number of men from the coal-mining industry who have been and will be called to the colors leaves a serious gap—but the situation can and will be met. America's "will to do" is more than equal to the demand.

The problem of getting coal from the workings to the tipple is as important as that of digging it. The miners would soon bury themselves if the coal were allowed to pile up behind them. A well-organized haulage system is the vital connecting link between the mine face and the railroad—the "neck of the bottle" that must be kept uncorked if the mine is to work to capacity, and if the owners are to do their part toward supplying the world shortage of fuel.

It took the prod of war to really "show up" animal haulage. The flop-eared, perverse mule has been associated with coal hauling for so long that some people had almost come to think that mules grew in mines, like mushrooms.

But when the war came, mule prices went up; owners began to realize that mule and horse haulage never had made a good showing. They were "ripe" for some better methods—and fortunately the methods were ready.

The owner or operator looking for increased production, setting down his arguments "for" and "against," will find these points in favor of internal-combustion-locomotive haulage as compared with animal haulage. The cost of a reliable locomotive has not increased as rapidly in proportion to the work it does, as has that of mules and horses; it will haul far greater loads per trip; it will keep at its task, hour after hour, all day, without requiring any rest between trips; if properly designed, it will operate successfully underground as well as on top, without giving off objectionable fumes; it will burn only a small amount of fuel in proportion to the work it does, and will require but little lubricant; it will not require a licensed engineer, but can be operated by any man who has a fair knowledge of machinery; being built properly in the first place, it will not require any heavy outlay for upkeep; and practically without deterioration when not in use, it will not add appreciably to the overhead operating expenses of the mine when not working.

To verify the belief that one of the solutions of the acute labor shortage in our coal mines is through the introduction of efficient haulage methods, an inquiry has been conducted among some representative concerns who have given this type of haulage a thorough trial.

Their reports would indicate that the day of animal haulage is now well past and that owners who look to gasoline power may also confidently expect and realize lower operating costs.

At Philippi, West Virginia, the Morrell Coal Co. has used internal-combustion haulage from the time it started in business. The power unit is a three-ton friction-drive locomotive, and its performance has been carefully checked by the superintendent, C. M. Wolfe.

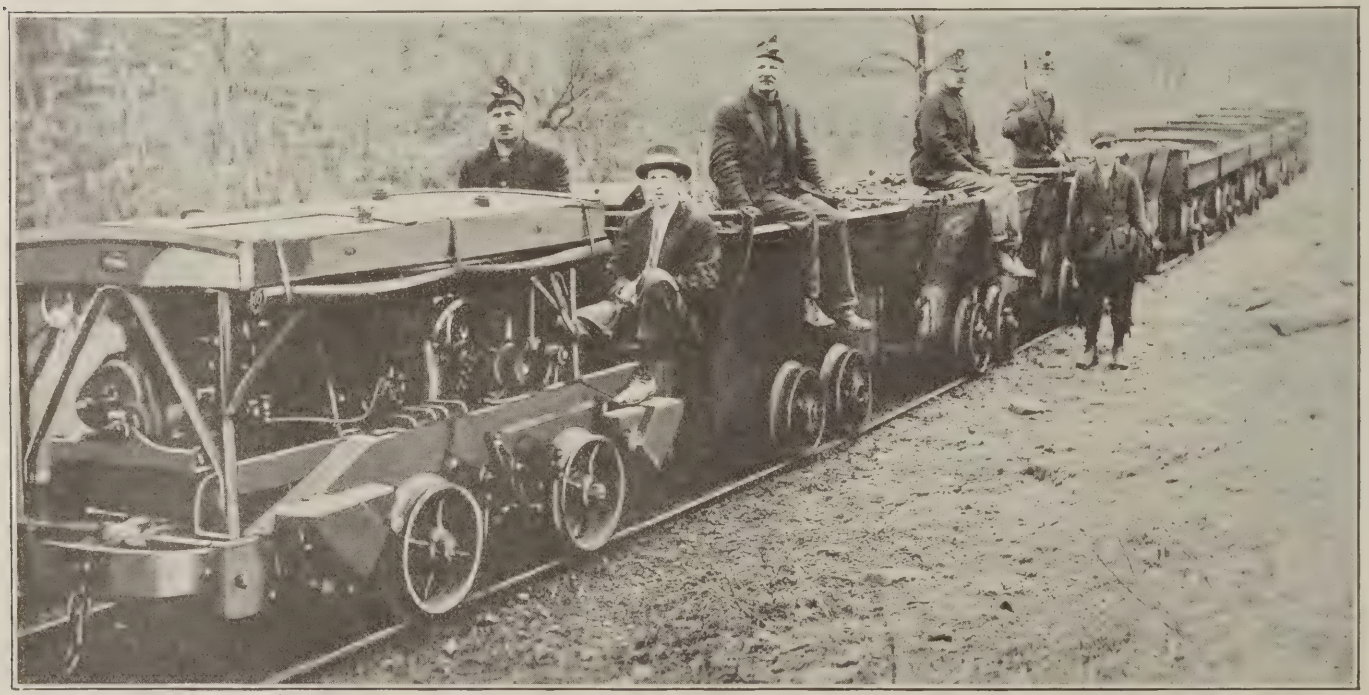


FIG. 1. GASOLINE LOCOMOTIVE WITH TRIP OF CARS AT SOUTHERN CONNELLSVILLE COKE CO., UNIONTOWN, PENN.

FIG. 2. LOCOMOTIVE WITH A SHORT TRIP OF LOADS, MORRELL COAL CO., PHILIPPI, W. VA.

Production averages about 400 tons per 8-hour day, and the locomotive handles the entire output with ease. It takes six-car trips, each car holding 1½ tons, and covers the round trip between mine and tipple in ten minutes.

So far—and the owners feel that a year and a half is long enough for a test—the locomotive has been economical both in fuel and lubricating oil. An average of 9 gal. of gasoline and a limited quantity of lubricant are used, and the outfit is operated successfully with only two men—neither of whom is an expert mechanic.

Using this type of power, these advantages are noted: Low operating and maintenance cost; saving in operator's wages, since no skilled engineer is required; ability of locomotive to pull extra-heavy load, taking up slack between cars without stalling; and ability to pick up speed quickly under load.

Over in an adjoining county, at Clarksburg, another company adds an enthusiastic word for gasoline-locomotive haulage. The Central Fairmont Coal Co. started its search for a worthy successor to the patient mule some years ago. Finally the president, D. Howard, found a type of locomotive that looked suitable. He questioned officials of other companies, owning the same make, and then ordered one.

Conditions at this mine put the locomotive to a really severe test. The haul is 3000 ft. long, starting underground and including a troublesome grade. These conditions did not, however, prevent the outfit from giving so good an account of itself that later the company ordered another of the same make. Both are now being used—and used hard—every day.

Both locomotives are busy nearly all of every day, but neither of them has ever shown any sign of weakening under "punishment." For about two years the upkeep has averaged scarcely more than $1 per month for each locomotive. When it came to recruiting competent operators, the officials found their troubles already settled for them by the locomotive builders themselves. The modern gasoline-haulage unit is operated and controlled in practically the same manner as is a motor truck—even the owner of a pleasure car would soon "get on to it."

With a big field of experienced truck and auto men to draw from, the Central Fairmont Coal Co. has had no trouble in locating operators of ability, men who can not only drive the locomotives forward and backward under load, but who can give them intelligent care whenever it is necessary.

Bearing in mind that each of this company's locomotives is in use nearly all day, and that they both pull heavy loads against stiff grades, the officials feel that their gasoline bills are exceedingly reasonable. Seven gallons per locomotive per day covers this item—a mere trifle compared with the cost of feed for enough mules to move the same tonnage.

The coke people, too, are "taking stock" of their haulage facilities and are finding animal power costly and unprofitable. The manager of the Southern Connellsville Coke Co. found in ten months' experience that his gasoline locomotive could make its 4000-ft. haul four times an hour. That means a round trip of more than a mile and a half every 15 minutes—32 trips each eight-hour day.

Loads at this mine average 400 bushels of coal. Figuring that the locomotive hauls more than 12,000 bushels per day for nearly 25 miles, and then covers an equal distance with strings of "empties" on the return trip, the consumption of gasoline and oil seems low indeed—5 gal. of gasoline and 1 qt. of lubricating oil. As may be judged from the illustration (Fig. 1), this outfit has few grades to contend with. Although the trip begins in the mine, no trouble is encountered with exhaust fumes—the owners finding that the locomotive operates about as satisfactorily there as on the surface.

The H. C. Frick Coke Co. is another large concern whose experiments with internal-combustion haulage have shown good results. At one of its plants—at Bute, in Fayette County, Pennsylvania—one gasoline locomotive of the friction-disk type has replaced eight mules and their drivers.

Following and profiting by the experiences of these operators, some of the strip-mining companies are already "dipping into" gasoline haulage with equally good results—though in their case the conditions are so different as to make the change even more striking.

For a "daylight" mine to adopt gasoline haulage, buying fuel at market prices, is a notable admission of the efficiency of the gasoline locomotive. A number of the large stripping companies are, of course, using steam locomotives that burn coal produced on the

spot; and it is hardly to be expected that any company would deliberately turn to gasoline machines unless convinced that the latter offered greater economies in operation.

The reasonable conclusion appears to be that, as capable men are taken by the draft, their place in the mines must be filled by better mechanical facilities in the form of digging, loading and conveying equipment.

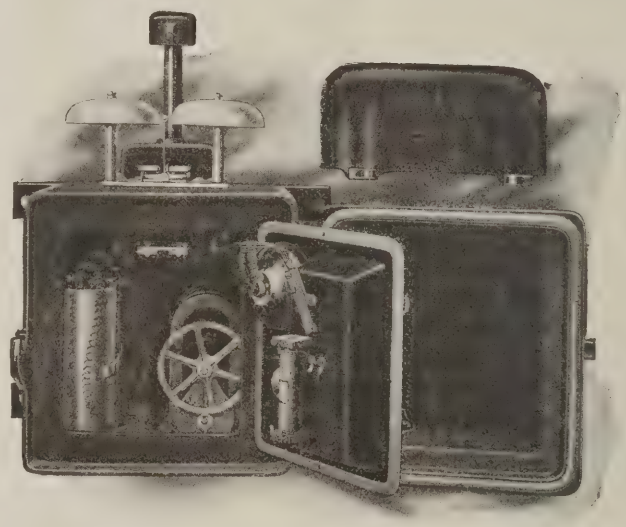
If loyalty to the nation that has given them their chance does not alone impel those who remain to stay on the job and work all the harder, perhaps the mere "motive of gain"—an extra ply or two in the pay envelope—may help to turn the trick. But if neither of these alone suffices, no doubt a resourceful administration will find some other way.

One can scarcely believe that the great minds of a nation that has done the apparently impossible in many other directions will allow anything to seriously interfere with the production of a great war essential.

The Nerves of the Mine

By L. B. Gawthrop
Philadelphia, Penn.

Of all uses to which the invisible force of electricity has been put by man, perhaps the most useful, the most important and the most far-reaching in its results is the transmission of intelligence. Efficient as electric power distribution may be, other means may be found to take its place should necessity require. There are no substitutes for the telephone, the telegraph, the wireless and the electric signaling system.



In practically all modern industrial plants the telephone and the electric signal play an important and a highly utilitarian rôle. In some instances the executive in his office may not only secure telephone connections with the heads of his various departments, but by means of instruments, such as electrical revolution counters and the like, may have actual communication with various important machines themselves and is thus enabled to know definitely at any time exactly what each unit is doing.

The coal mine is in many respects as intricate an establishment as many factories or other industrial institutions; and in the mine, also, the electrical transmission of intelligence is highly important to the smooth running of the organization, to the production of a vital national necessity, and in not a few instances to the protection of property or the preservation of life itself.

It is needless to say that signaling devices and telephones are worse than useless unless they are reliable. In any system of intelligence-transmission as intricate and complicated as that employed in a big mine, each unit and each element must be absolutely dependable. In this class of apparatus the Electric Service Supplies Co., of Philadelphia, Penn., has specialized for years and now has a line of equipment that it is satisfied is highly efficient and reliable for the purpose intended. Its mine telephones, electric signal switches and mine signal push buttons are built "on honor," of the best materials obtainable for the purpose and after designs the utility of which has been proved thoroughly in extensive practical use.

A good intelligence-transmission system in a coal mine might rightly be called the nerves of the organization. Such a system is vitally essential to maximum production, since it is through it that orders and directions are conveyed to the most remote as well as the more adjacent parts of the operation. This is accomplished quicker and more certainly and accurately by electricity than by any other means.

Giving orders quickly and intelligently naturally involves the use of the telephone, but other signaling may be done with bells and buzzers or incandescent lamps provided with their proper respective control equipments. The telephone is particularly useful to the superintendent or other official who desires to keep in close touch with all parts of the operation. This service it performs admirably, since when, we will say, the superintendent wishes to give the mine foreman certain instructions, he merely rings up, gets his man, has a few minutes talk with him and hangs up. A great saving of time has been accomplished. In addition, the executive originating the order has the assurance

EFFICIENT ELECTRIC MINE TELEPHONE

that his message has been given to the proper person exactly as he wished it given, since he spoke to the man himself just as surely as if he had conversed with him face to face.

The same applies with equal emphasis to the mine foreman or electrician who may wish to get in touch with the superintendent or any other person about the mine. The advantages enjoyed by the officials through the use of the telephone are as great in proportion as those accruing to the superintendent or other executive responsible for the operation of the entire plant.

Great as are the advantages of the electric transmission of intelligence, exemplified most forcibly by the telephone, it is in times of emergency that its full value is most significant. A failure of the mine fan, a suspension of power, in fact any emergency affecting the safety of either life or property, demonstrates the true value of the ability to rapidly and accurately transmit orders and instructions. These are the occasions when a mine telephone is invaluable; in ordinary day to day operation it does much to insure the production of maximum output, which in these days is a vital necessity.

Specializing in the Mine

By J. APPLETON and J. SOMERS
Ironton, Ohio

SYNOPSIS—*There was a time when a miner was a skilled workman and performed all the operations necessary in coal production. Times have changed, and the miner today is almost exclusively a wielder of the shovel. Specialization and concentration of operation have done much to boost output when output is badly needed.*

THE serious problem which at this time confronts the entire coal industry is that of mining sufficient fuel for future requirements. This must be accomplished in the face of an unprecedented labor situation and the impossibility of getting enough needed new equipment promptly, owing to manufacturing conditions brought about by the demands of the war.

Every new application and development which will accomplish something toward this end should be carefully considered, and this article is prepared with the hope that it may be of some service to coal operators in solving the problem now before them.

Best results are obtained from labor and equipment when the work is so divided that both men and machinery are operating without interruption due to any one or more parts that perform the cycle of operations being delayed. In the ordinary method of coal mining sufficient attention is not paid to this point, with the result that both labor and machinery stand idle when they might be operating to advantage.

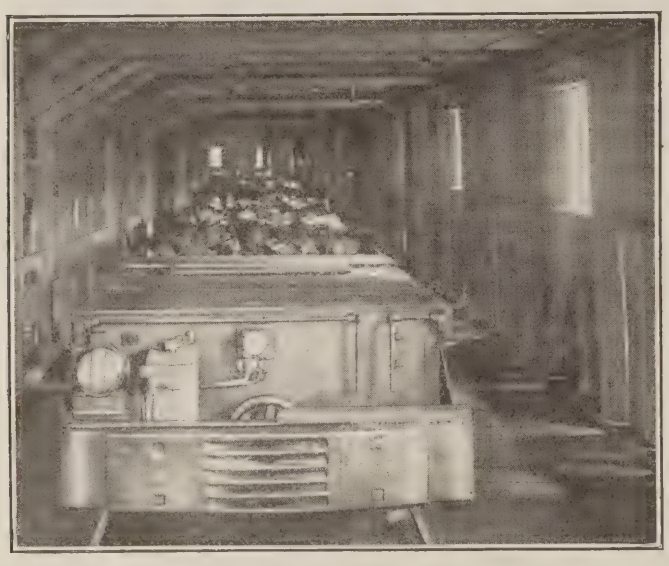
In manufacturing operations, maximum output and reduced costs are obtained by specializing the work each man does. Both he and his equipment keep on working continually at the particular job laid out for them and are not kept waiting by the other operations which are necessary to complete the finished product.

LOCOMOTIVE IN A ROOM

Let us see how this plan works out when applied to coal mines. There was a day when the miner cut his coal with a hand pick and also had all the rest of the various operations to do pertaining to coal production.

The cutting machine eliminated the pickman, and the coal miner became a coal loader. This was a decided step forward and increased the amount of coal per capita. But it did not go far enough, because the coal miner still had other duties to perform in addition to loading coal, such as timbering, shooting and sometimes laying the track.

Under the present system each miner is assigned to a particular place in the mine, and if he does not work the place remains idle. He is paid by the car for the amount of coal he loads, the other work he does being included in this price. If a man changes places he may have to do a lot of preliminary work which really be-



LOCOMOTIVE AND CARS ON ROTARY-DUMP TIPPLE

longed to his predecessor before he can start loading the coal which is the basis of his day's pay; and this he naturally objects to, as it reduces his remuneration for that day.

To make this clearer, let us consider the longwall method of mining, in which the men are not assigned regularly to any particular place but are assigned each day to any portion of the face where there is coal ready to load. For obvious reasons the longwall method of mining cannot be generally adopted, but its good features if applied to the room-and-pillar method would produce far better results than are now secured.

To explain in detail what is meant, let us consider the method used at the Bailey Coal Co. mines at Toler, Ky., where Lawrence Farrell has worked out a system which is believed to be unique.

Instead of having the loaders take up a large part of their time each morning preparing their places and the coal for loading, which means that cars and storage-

A TRIP IN THE TIPPLE

battery locomotives remain idle until this work is done and the coal can be loaded, this preliminary work is done by a few extra men who specialize on this class of operations and therefore become expert in their performance. Details of the system Mr. Farrell has so successfully worked out are as follows:

All the work of bringing down the coal is done at night. The coal is first cut; then the track is laid. A man with an electric drill follows the tracklayer, boring the necessary holes, and a shotfirer follows. Under this arrangement all the tools the coal loaders need are a pick and a shovel, which they can easily carry around from place to place. In the morning, at starting time, each loader is assigned to some working place where the coal is loose and ready to load, care being taken to concentrate the men available so that gathering and hauling of the coal may be done with efficiency and at a minimum expense.

In this way the cars and locomotives are put into operation as soon as the men start work instead of remaining idle several hours until the coal is made ready to load. This also applies to the tipple men and others who have nothing to do until coal is actually being hauled.

How many mines are there where it is 9 o'clock or later before the hauling of coal can be commenced, the cars and locomotives during this time remaining idle and nonproductive? To accomplish the results outlined above at the Bailey mine, only two extra men are required; and as they do nothing else, they become expert at this work. Proficiency, especially in drilling and shooting, means much.

LOCOMOTIVE AND TRIP IN A HEADING

Eliminating this special work means that the class of labor now procurable can be used to advantage. Loading coal only is done by these green men, who could not be used for drilling and shooting. Consequently, the maximum efficiency is secured from the labor available.

The cost of the extra men doing the drilling and shooting, also the powder used, is not charged against the loaders. It has been found that the increased amount of coal obtained more than offsets this expense. Also, by relieving the loaders of this work, the men are much more satisfied. They stay at the mine instead of quitting for a slight pretext, as they did under the old method.

At the Toler mine 25 mine cars designed by Captain Bailey are employed, the special feature being the large capacity of the car with minimum height. This has been accomplished by making the car overhang the wheels. A capacity of 2½ tons per car is obtained with a car 10 ft. long and 32 in. in height, this being the same

BORING A SHORT HOLE IN THE FACE

dimensions as the Ironton storage-battery locomotives employed. These cars are shown in the accompanying illustrations.

With only 25 cars and two storage-battery locomotives, 450 tons of coal per day are handled over a haul which is unfavorable, the length being 2800 ft. and the entire distance having a grade against the load, in some places reaching 5 per cent. The amount of coal loaded per man is high, averaging about 20 tons per man. The mine cars are dumped eight times per day.

With labor specialized and concentrated in this way, and supplemented by up-to-date methods of gathering and hauling by means of storage battery locomotives much can be accomplished towards meeting the present serious situation; and we hope this article may be the means of some coal operators investigating what has been accomplished with this method and the equipment employed in this mine. The method is just as practical and possible in other operations.

Minecdotes

A Slight Mixing of Words

The mechanical engineer had been having his troubles. The mines were working full time and full handed, and consequently turning out a record tonnage. Repairs were accordingly heavy, and when something broke a duplicate part had either to be made in the shop or purchased and delivered in record time.

The company operated several distinct plants, some of which were miles from the office. When a gear failed on, we will say, a picking table, it meant that the engineer must either ride horseback several weary miles, take a passenger train if convenient, run his chances of getting a ride on a "shifter," or walk. The important thing was to get to the disabled machine, collect the necessary data and get a night-letter off via the order clerk as quickly as possible regardless of personal convenience or inconvenience.

One day, after being called to one of the remotest operations to measure up and order a pinion, the mechanical engineer took up with the superintendent the question of the latter's making his own measurements for gears when occasion demanded. He assured the superintendent that it was needless to bother whether a gear was of the involute, cycloidal or radial flank contour. It was necessary, however, to state the material of which the gear was made (cast iron, steel casting, steel forging, rawhide, brass, bronze, fiber or cloth), the method of manufacture (cut or cast), outside diameter, number of teeth, width of face, diameter of bore, size of keyway or keyways if any, set screwing if any, length of hub, and the position of hub with respect to the center line of the gear face—that is, most hubs were set central and extended as far on one side of the wheel as on the other, while some hubs extended farther on one side than the other, or extended on one side only. The engineer explained also that pinions were sometimes shrouded, and in such a case it would be necessary to state the width of the working face (most easily secure by measuring the face of the gear with which the pinion meshed), the total width of the pinion tooth, the total width of the pinion over the shroud or shrouds, and state whether the shrouds were "full" or "half," one end or both.

The superintendent was much interested, as the mechanical engineer was speaking a language that he only imperfectly understood. He knew well what the face of a room meant, but the face of a gear was another matter. Involute, cycloidal and radial flank did not particularly interest him—they were out-and-out "highbrow," and non-essentials anyway. But he had to know all about shrouding. The engineer accordingly spent some time—several minutes in fact—in explaining the theory and practice of this method of strengthening gear teeth. He impressed upon the superintendent's mind that shrouding was practically always either "half" or "full," and on either or both ends. He finally made everything clear, and after counting the ties for four or five weary miles got a cold supper and a "call down" from Mrs. Engineer for being "so awfully late."

A week or so later, as the engineer was preparing to leave the office one evening, the telephone rang. The superintendent was on the wire. The pinion on the belt conveyor had broken. He had another, but thought it would be wise to keep one spare on hand. He had measured the piece and would give him the figures. The engineer got his notebook; he had obtained the measurements for that pinion a year or two before and carefully preserved them in a card index, as he had all other data of similar nature, but he wanted the superintendent to gain confidence in himself. So when he had his notebook and pencil ready he told the superintendent to "shoot."

Slowly and carefully the superintendent gave his figures, the engineer replying "Yes," "Uh-uh," "Are you sure of that?" "All right," etc. The pinion was of cast iron, it was so many inches in outside diameter, had 15 teeth, the working face was 4 in., the bore was $2\frac{13}{16}$ in., the keyway was $\frac{3}{8} \times \frac{3}{4}$ in., the total length was $5\frac{1}{2}$ inches.

"Is that all?" queried the engineer.

"Why ye—No. It's got ah—er—ah—Well, I know what it is, but I've forgot what you called it. As I remember what you told me this pinion has a complete suit of grave clothes on each side!"

In due time the superintendent got his pinion—*full shrouded* both ends.

Maximum Efficiency from Mine Cars

To a large extent maximum efficiency in coal-mine operation depends upon the facility with which the mine cars can be operated, says "Graphite Mine Car Lubricants," an exceedingly informative sixteen-page booklet compiled by the United States Graphite Co., of Saginaw, Mich., for gratuitous distribution. Therefore, to prevent delay and expense from undue wear and tear and to insure quick and easy handling it is necessary that mine cars be well lubricated. . . . Graphite grease is peculiarly adapted to this class of service, and if of the right sort will furnish lubrication of a superior degree and at the same time remove many of the objectionable features encountered in the use of oils and other greases, among them that of excessive labor cost.

Steel Mine Ties

By G. A. RICHARDSON
Philadelphia, Penn.

SYNOPSIS—*At a time when maximum production is highly desirable, steel ties possess many advantages over wooden ones. Although slightly higher in first cost, the steel tie is more efficient, especially in low coal beds; lasts longer; can be laid quicker and much more easily. The miners themselves prefer the steel ties because their use enables them to earn more.*

HOW can we save labor? How can we increase production? These two questions, important at all times, have become doubly so at the present; and we all know that coal-operating officials are finding themselves at their wits' ends to keep pace with increased demands on the one hand and a big reduction in their working forces on the other. Hence, when it is stated that the use of steel mine ties will increase production, save labor and reduce operating costs (a statement which has been made many times before), it should come home with particular force. Even if operating costs were not reduced or were made slightly greater, the first two parts of the statement justify a thorough investigation, while the complete statement expresses the cardinal aims of all business men.

The steel mine tie is no longer an experiment. It has been used successfully and for a long enough time to establish its superiority over the wooden tie, which it is rapidly replacing. As far back as 1910, one maker of steel ties put out 50,000. Sales of the Slick steel mine tie, an improved type which made its appearance on the market at the beginning of 1915, were 400 per cent. greater in 1916 than in 1915; and though further big increases have been seriously hindered by the difficulties experienced in obtaining the necessary steel, the mere statement that nearly 300,000 of this one type were sold in one section alone in 1917 gives a good idea of the demand which exists.

At the present time there are several well-known types of steel mine ties on the market. Of these, it is my intention to speak more specifically of the type known as the Slick steel mine tie, because I am firmly convinced that it possesses special features of design which make it by far the best for all-around use. Patented Jan. 19, 1915, this tie embodies improvements made as a result of a thorough study of then-existing types and their advantages and disadvantages.

In taking up the question of the actual advantages gained by the use of steel ties, the fundamental points on which these are based are as follows: (1) Size and weight; steel ties are smaller in size and lighter in weight than wooden ties for the same class of service. (2) Life; steel ties will give much longer service. (3) They are easily and quickly installed or taken out, due to special features of design.

Other points than these might be mentioned, but they would be more properly classified as subdivisions of the above, and in fact the three fundamental ones are so closely dependent on each other that it is difficult to separate them entirely. They will be brought out as the subject is developed.

Let us consider first of all the advantages of steel ties as compared with wooden ties from the standpoint of size and weight. A medium-weight Slick mine tie for 36-in. gage, complete with fastenings, will weigh about 10 lb., whereas a 3 x 4-in. wooden tie will weigh from 14 to 16 lb., depending on the kind of wood. A light-weight Slick tie for this same gage weighs only 5 lb. These savings in themselves, though important, would not warrant any unusual consideration were it not for the size and shape of the ties.

Steel mine ties are compact and have a shallow section; this latter fact makes it possible to materially modify track-laying practice. Owing to the thickness, which is only ½ in. for the light and medium-weight ties, it is possible to space them much farther apart than could be done with wood ties, because the rail between ties is supported by the floor. The actual distances of spacing will of course vary with the mine and the conditions encountered. In a large mine in Westmoreland County, Penn., one of a group that has used over 50,000 steel ties in the last two years, it is stated that wooden ties are spaced as close as 18 in., while the usual practice with steel ties is to place one at each joint and enough in between to make one tie to about

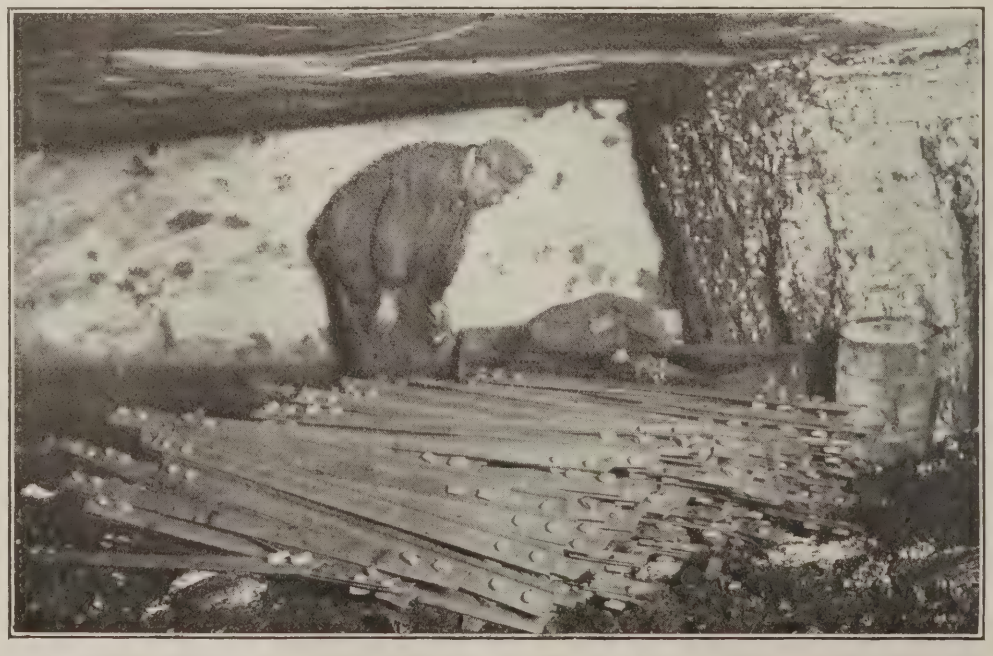


FIG. 1. PILE OF STEEL TIES, SHOWING SMALL SPACE OCCUPIED

FIG. 2. TRACK WITH BOTH STEEL AND WOOD TIES

every 10 ft. If wooden ties are not spaced fairly close together the rails are apt to break because of lack of support. This particular group of mines uses medium (No. 2 Slick) ties for the most part, with 20-lb. rail at 40-in. gage for all but heavy hauling.

At another large group of mines in Indiana County where the light-weight ties are used with 16-lb. rails for all but heavy service, the usual spacing is three steel ties per 15-ft. length of rail as compared with at least five wooden ties.

It can be seen from these two examples that it is possible to reduce the weight of a track section materially; in fact, to such an extent that two men can readily lift and carry a 15-ft. section of track with 16-lb. rails. This ability to move the track readily is of the greatest importance in mining.

Another advantage which results from the extreme lightness and compactness of the steel mine ties is the fact that a miner can readily pick up as many as half a dozen and carry them under his arm to the place where he wants to use them. This means that he does not have to waste time waiting for an assistant to come and help him. He can go ahead when he gets ready, and in practice does so. Some idea of the small amount of space taken up by these steel ties can be gained from Fig. 1, which shows a pile of 360 such ties stored at the side of a main entry in a 3½-ft. coal bed. A comparison of the size of the pile with that of the spike keg in the rear, or the stooping man, clearly illustrates what it has been my endeavor to bring out. This picture was taken the latter part of June of this year.

Probably one of the best known arguments which have been made in favor of steel mine ties is that regarding the increased headroom which can be gained by their use. Owing to the fact that their depth is so slight, a gain of fully 2½ in. can be made. What this additional headroom means where the beds are thin is only too evident to the practical mining man. Primarily, it allows of the use of larger mine cars and heavier loading, and eliminates the necessity of cutting channels for wooden ties. It should not be overlooked, however, that even a few extra inches will frequently facilitate loading, especially in cramped places, and thereby increase production. In many mines with medium or low coal beds, where wooden ties have been laid on the room floor, it has been impossible to introduce a mining machine into the room on account of the height of the machine. With steel ties and the greater clearance thus afforded, the same mining machines can be used. This alone is sufficient to recommend the use of the steel tie in such locations.

Where wooden ties are used in thin beds, it is almost invariably necessary to cut channels for them in the floor in order to gain the needed clearance. It is here that a marked gain or loss in production can be made. A miner working in a 3½-ft. bed made the statement that where it was necessary for him to use wooden ties and cut the channels for them it took nearly two hours to put in 30 ft. of track. With steel ties the job could be done in five minutes. Now, in this particular seam the average loading rate is four to five cars of 1½ tons capacity each in two hours; hence the miner and his helper can make a material increase in the amount of coal sent out. When this is multiplied many times, according to the number of miners working, it becomes an important consideration.

Fig. 2 was taken in a 3½-ft. coal bed in Indiana County, and brings out clearly several points. In the first place, the comparative space taken up by wooden and steel ties when in place is clearly shown. A shortage in the supply of steel ties here necessitated using some wooden ones. This is not good practice, because the wooden ties are so much the thicker that unless a great deal of work is done a humpy track results. One such hump shows clearly in the picture.

Fig. 3, taken in another room in the same mine, shows an actual installation of track laid on steel ties as it appears under normal working conditions. Steel ties are so thin that they do not ordinarily show up clearly in a photograph.

The life of ties is naturally a factor of considerable importance, especially where an increased first cost is necessary. This is, however, a factor that is highly indeterminate and it is useless to give exact figures. There are so many things that enter into consideration, all of which have an important bearing, that no general rule can be given except to the effect that steel ties will unquestionably give better service under almost all conditions than wooden ones, and cost less per year.

As a rule the natural tendency is to think of life of ties in terms of the comparative lengths of time which they will stand up under normal conditions of service, and this is the right method in the case of ordinary track where it is perfectly possible for even wooden ties to last many years. The average condition met with in the mine is not a normal, but an abnormal, one. Not only are ties exposed to excessive moisture in many cases, but mine operation necessitates that a large part

of track laid must be taken up and moved quite frequently. It is here that the serviceability of the steel tie begins to come out most prominently. Wooden ties must be spiked, and frequent spiking shortens their life markedly. Notching to receive the rail has a similar effect. Even where the tie is not cut the statement is made that it can seldom be used more than twice, giving an average life in many cases of barely more than three to four months. Steel ties, on the other hand, will last indefinitely, and while they will rust to a certain extent this does not seem to interfere with their usefulness. They are being used continuously where there is excessive wetness.

Another reason why steel ties have a longer life than wooden ones is the fact that they are so compact that the miner will pick them up and move them, whereas he will allow the more bulky tie to lie in place.

A third fundamental advantage of steel ties is that they can be easily and quickly installed and removed, due to special features of design. As already mentioned, size and weight have a great deal to do in giving this advantage, but the special design outweighs even these. The miner wants something which can be easily and quickly put down with a minimum of effort. This has been secured through the elimination of spikes, also the necessity of setting the track to gage.

This has been accomplished by the use of flanged buttons in the case of the Slick tie. These buttons, which have been made amply large to stand the wear and tear of rough service, are so placed that they give the exact gage of the track automatically when the rails are placed for fastening. The buttons themselves are so made that they can be turned with comparative ease by means of an ordinary adjustable or solid wrench. They hold securely in any position by the friction of the rivet which keeps them in place. A single quarter turn is all that is necessary.

It can be readily seen that a tie which is self-contained and requires no extra fastenings is a big help down in the mine, eliminating many of the hindrances and wastes due to lost parts. When it is considered further that no adjusting to gage is necessary, that a few seconds are ample to fasten the track securely in place, and that the only accessory, the wrench, is easily carried, the advantages are apparent.

In many mines wrenches are never used at all, the buttons being knocked into place by means of a hammer or hatchet. This is not good practice and is not recommended, but nevertheless a large user of the light-weight ties made the statement that it is followed almost universally in his group of mines and there has been no complaint. This speaks well for the ruggedness of the ties.

When desired splice sections can be furnished, but the ordinary practice in the case of the lighter-weight ties is to do without splices of any kind. The grip of the buttons is so secure that the placing of one or two ties at each joint, the number depending on the size of tie employed, answers all purposes quite satisfactorily.

Steel ties are popular with miners in robbing pillars because of the ease with which they can be put in place and carried away. No spike bar is needed in taking the rails up, and the joints can be knocked loose. This means that the track can be readily moved while the roof is coming down, and this results not only in a saving of rails but of ties as well. Too often where rails spiked on wooden ties are used the entire track is lost.

In both room and entry work the last 15 ft. of track must be taken up each time the face is cut. Where wooden ties are used the miner does not like to go to the trouble of spiking the rails down, with the result that his car is apt to go off the track. He and his helper are then likely to get disgusted and go home for the day, and production is lowered just that much. The rails can be readily and quickly fastened down when steel ties are used.

A convenient method of extending track in rooms when steel ties are used is as follows: The mine track may be prolonged to the face workings by laying a pair of loose rails on their sides, projecting from the tie-supported track. Each loose rail fits along the inner side of each extreme track rail, with the head of each loose rail outward and the web approximately horizontal, so that the loose rail rests upon the side of its head and the edge of its flange. The head of the loose rail fits between the head and flange of the upright track rail, and the clamping buttons fit between

FIG. 3. TRACK LAID WITH STEEL TIES

the head and flange of the loose rail, thereby holding it in place. This latter position, while it allows the loose rail to be slid forward and backward, prevents it from accidentally getting out of position. The loose rails are easily applied to the assembled track and may be extended, as desired, to the working face by sliding the rails lengthwise until their ends reach the face workings. No fastenings or special fixtures are necessary, as the extension rails are held in place by the button fastenings in conjunction with the upright rail. The mine-car wheels run on these extension rails on their flanges, which are supported by the rail webs.

There is no question that taken all in all miners favor the steel tie in preference to wooden ones, and it is an actual fact that labor discontent and troubles have arisen over this very question. Where both kinds of ties are used it is customary to give out the steel ties for use in the low coal, with the result that the other men feel that they are being discriminated against. Perhaps the best evidence of the liking which the miners have for the steel ties is the statement that where the supply of these ties is limited a pile left lying loose will rapidly disappear, each man taking and hiding as many as he can for his own use.

The question of cost is always an important one.

The miners that I have spoken with seemed to feel that the reason steel ties were not furnished was that they cost more than wooden ones. This may be true in some cases, although the operating officials stated emphatically that this was not the reason, saying that it was simply due to the fact that they could not secure such ties as fast as they would like under existing conditions. It is true that steel ties do cost more than the wooden ones, but first cost is a small part of the expense in any mine. If increased life, increased production, a saving in equipment, etc., result, it is negligible.

Another thing that must not be overlooked is the fact that while the miner is not paid for the time he employs in laying and taking up track, he is then not only decreasing his actual production but by virtue of this fact is increasing the overhead that must be charged against each ton of coal produced.

As stated in the beginning, the very fact that sales of steel ties continue large and are on the increase shows conclusively that they are meeting requirements. It must not be forgotten, also, that wooden ties are constantly becoming more and more difficult to secure and are rapidly approaching steel ties from the standpoint of cost. Many mines—not all small ones either—are going over to steel ties entirely, and this includes ties for switches as well as straight track.

Peat Deposits of the United States

According to the United States Geological Survey, Department of the Interior, the commercial development of the vast peat deposits in the United States would materially relieve our present shortage of fuel. Although peat has never been largely used as fuel in this country because of our abundant supply of coal, which can be more readily prepared for consumption and in normal times more cheaply brought to the consumer, it has long been used in Europe, where 15,000,000 to 20,000,000 tons are consumed annually in generating heat and power.

The attempts made in this country to manufacture peat fuel on a commercial scale have not been successful, but the failure appears to have been due not to a lack of market for the product but to the lack of sufficient capital, to the inexperience of the operators, and to preventable engineering errors. It is said that air-dried machine peat, which is but little inferior in calorific value to many grades of lignite coal, can be produced at a cost ranging from 75c. to $2.50 a ton, the exact figure depending on the size and the efficiency of the plant; and it is believed that in some parts of the country it could successfully compete with other fuels for both domestic and industrial use. It burns with little smoke and ash, and wherever it has been used in this country it has proved very satisfactory and has found ready sale as fast as it has been produced.

The wide interest felt in the larger use of peat in the United States is expressed in recent messages from the governors of Maine and Massachusetts to the legislatures of those states, recommending an investigation of the local deposits of peat and its possible use to relieve the present shortage of fuel.

The lack of other fuel in many European countries is now being supplied in part by an increased use of peat. According to United States Commerce reports 216 peat machines were in operation in Norway in 1917, compared with 55 in 1916 and 36 in 1914. Among these were two automatic machines, each costing $13,400, having a daily capacity of 30 to 40 tons of fuel, and requiring only two men for its operation.

Peat consumed in a properly designed gas producer yields gas of good quality and in abundant quantity in comparison with the yield from coal, as well as many valuable byproducts. This is perhaps the most effective utilization of peat fuel for generating heat and power, because peat that is to be used in this way does not need to be so carefully prepared nor so thoroughly dried as peat that is to be consumed under steam boilers.

Specific information with regard to the use of peat in gas-producing plants and for other purposes is given in a bulletin prepared under the supervision of the United States Geological Survey but published as Bulletin 16 of the Bureau of Mines, from which copies of it may be obtained.

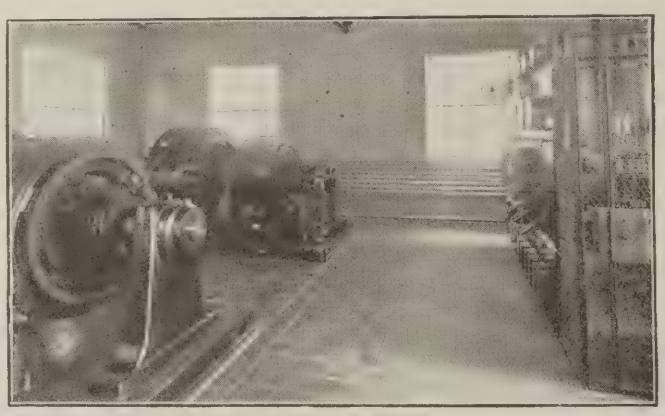
Coal Age Index

The indexes to *Coal Age* are furnished free to all who ask for them. The index for the first half of 1918 will be ready for distribution next week, and a copy can be had by addressing a post card to the Subscription Department of *Coal Age*.

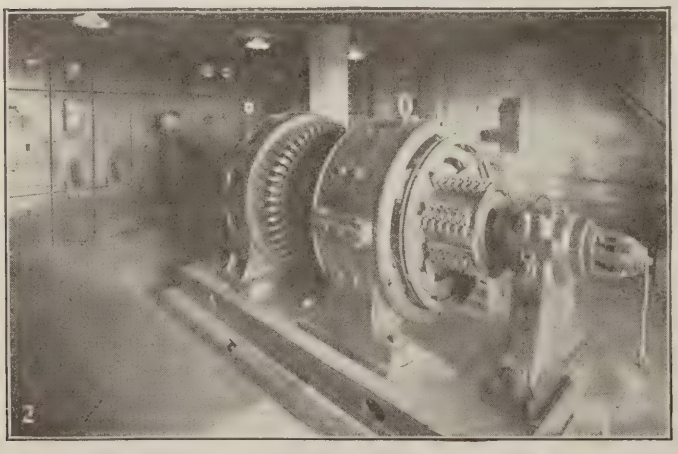
Ideas and Suggestions

THE coal-mining industry is confronted this year with the task of producing more coal than was mined in any other year of its existence. It must do big things in the way of production if the exacting demands of our war machine are to be satisfied. To win the conflict in which we are now engaged American plants must turn out more guns, more ammunition, more ships, more airplanes, more clothing—in fact, more of everything. In the final analysis this means more coal, for without fuel industry must cease to function. The relative value of little things to the larger undertaking of winning the war cannot be overlooked, and in no industry is this statement more true than in coal mining. Sadly depleted of man power, with equipment and machinery on the verge of breakdown because there is no letup for repairs, many coal-mining plants have been enabled to work day after day only by the ingenuity of their engineers. To assist the entire industry by the interchange of ideas that will lead to greater and more efficient coal production is the basic idea underlying the "Ideas and Suggestions" department of *Coal Age*. Therefore, if you know of a plan or of a device that proved its worth in time of need, write it up for the aid of others who may at this moment be in need of it. If you have a suggestion to make which will lead to more steady and more result-producing work on the part of the mine workers, make it directly to the industry through the columns of this journal. Diagrams, photographs and sketches that help put the idea over should accompany all manuscripts. Aside from enabling you to do your part in assisting the industry, is the fact that *Coal Age* pays liberally for all ideas and suggestions suitable for publication.

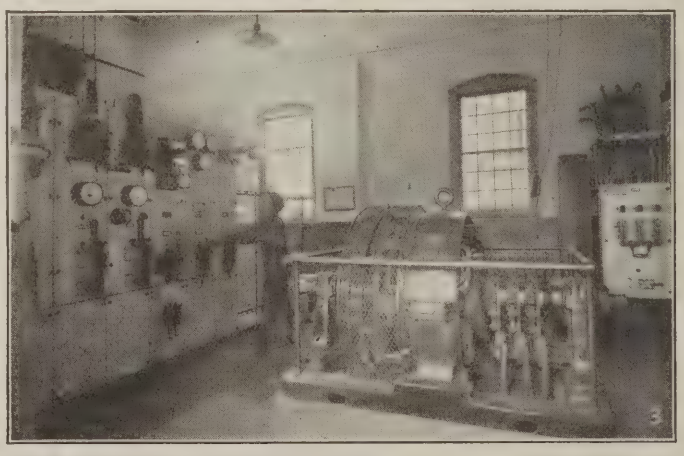
Electrical Labor-Saving Devices in Coal Mining



By GRAHAM BRIGHT
East Pittsburgh, Penn.



SYNOPSIS—*If coal production is to be maintained, all labor-saving devices available must be employed in mining. It is noticeable that practically all such devices now in use are electrically driven. It would appear that as men become scarcer machines must take their place. Greatest efficiency will be attained when a few experienced men operating machines supplant the large number of more or less ignorant and inexperienced miners usually employed.*



THE great increase in the demand for coal, coupled with a decrease in the supply of workmen and an increase in the cost of labor, makes it imperative that in order to keep up the production of coal labor-saving devices must be utilized to their fullest extent. It is true that many mining companies have installed considerable labor-saving equipment during the recent past, but the acute conditions brought about by the war make it necessary to leave no stone unturned to increase production. Although many labor-saving devices are more or less of a mechanical nature, a large proportion of them depend upon electric power for their operation. Since all mines use more or less power, there is a considerable field in the power department to install labor-saving devices. Where steam power alone is employed, some economies can be effected by the use of stokers, coal- and ash-handling equipment, feed-water heaters and purifiers. However, to effect real economy —not only to save labor but to cut down the cost of producing power—the steam should be replaced by the electric distribution with current either generated in an isolated plant or else purchased from a central-station company.

Where central-station power is available it often shows much greater economy both in regard to the amount of labor employed and the cost, when compared to an isolated electric plant. An isolated electric plant will effect some saving in labor, owing to the higher economy of electrical apparatus when compared with steam. The greatest economy, however, is often obtained only with the use of central-station power. I might cite one case of a mine in Alabama which is operated entirely by steam. Water is obtained from a river pumping plant, necessitating a separate boiler plant. The boiler plants alone are operated by the following labor: Main boiler plant, 6 day firemen, 1 day foreman, 4 night firemen, 1 night foreman, 6 ash rustlers; river boiler plant, 1 day fireman and 1 night fireman.

By the use of central-station power all of this labor could be dispensed with. Under present conditions the cost of labor at the boiler plants alone would be as great as the entire power bill, if central-station energy at ordinary rates were used. Central-station power has a further distinct advantage in increasing the output of a mine. The principal business of a coal-mining company is to mine and ship coal, and the operating force is generally selected with this end in view. The efficient production of electric power is a business by

FIGS. 1 TO 3. SUBSTATION EQUIPMENT INSTALLED AT COAL MINES
Fig. 1—Two 200-kw. synchronous motor generators, capable of supplying mine with capacity of 2000 to 3000 tons per day. Fig. 2—Mine substation with 200-kw. motor-generator set. Fig. 3—Synchronous converter of 500-kw. capacity

itself—entirely different from that of mining coal. As it is practically impossible to obtain men expert in both fields, a mine can be operated much more efficiently if all the time of the operating force can be devoted to the production and shipment of coal.

With purchased power most of the motors outside of the mine can be of the alternating-current type, receiving their power from static transformers, which in turn do not require any attention. Direct-current power for haulage and cutting is obtained from motor-generators or converters, which require only an occasional inspection.

Fig. 1 shows a substation equipped with two 200-kw. synchronous motor-generators capable of supplying power for a mine having a capacity of 2000 to 3000 tons per day. Fig. 2 shows a substation located inside of a mine equipped with one 200-kw. motor-generator set. Power is received from a cable installed in a borehole from the surface. Fig. 3 shows a synchronous converter of 500-kw. capacity. This equipment will require much less attention than a steam plant of the same capacity.

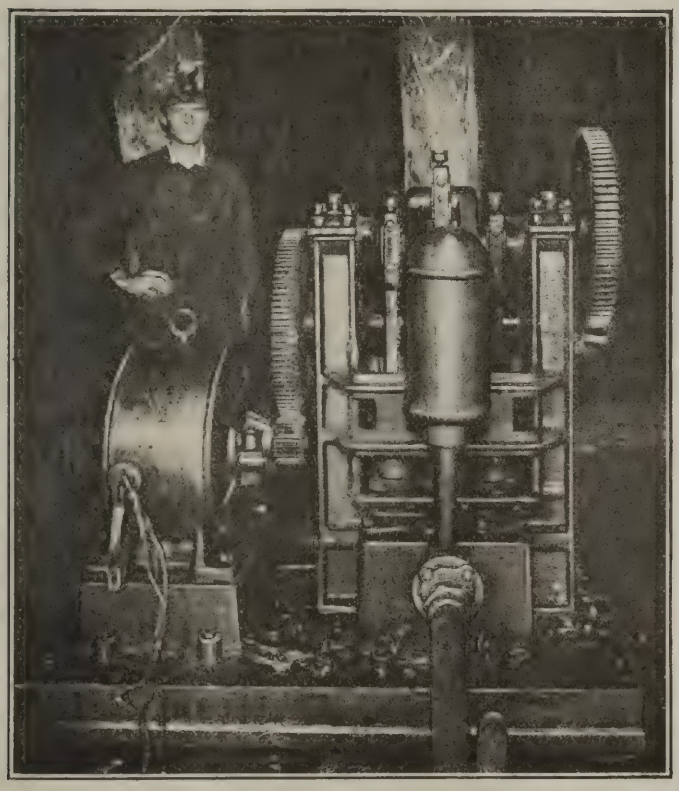


FIG. 4. GOULDS MOTOR-DRIVEN TRIPLEX PUMP

Practically all coal mines have to pump more or less water. The amount handled ranges from little or none in some of the drift mines of the bituminous field to several times the weight of the coal output at some of the anthracite operations. Where steam or compressed air is used for driving mine pumps, inefficient operation takes place.

Steam- or air-driven pumps require considerably more attention than motor-driven machines, and their poor efficiency, coupled with the pipe-line losses, means that more steam must be generated and more coal burned under the boilers, entailing not only more cost but more labor than when motor-driven pumps of similar capacity are employed.

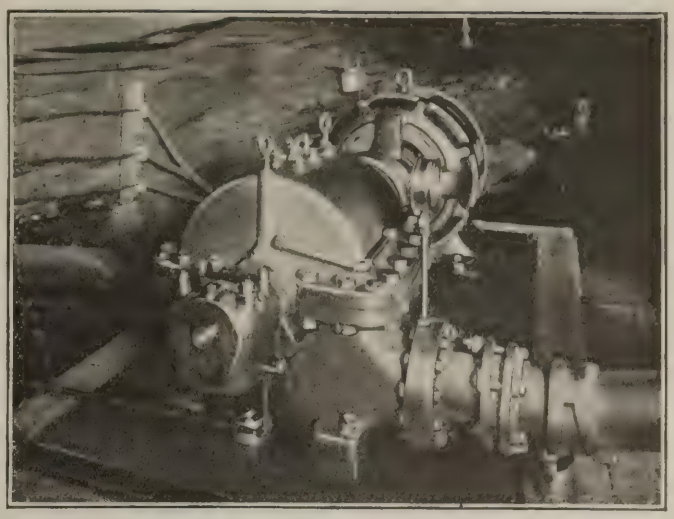

FIG. 5. GOULDS MOTOR-DRIVEN CENTRIFUGAL PUMP

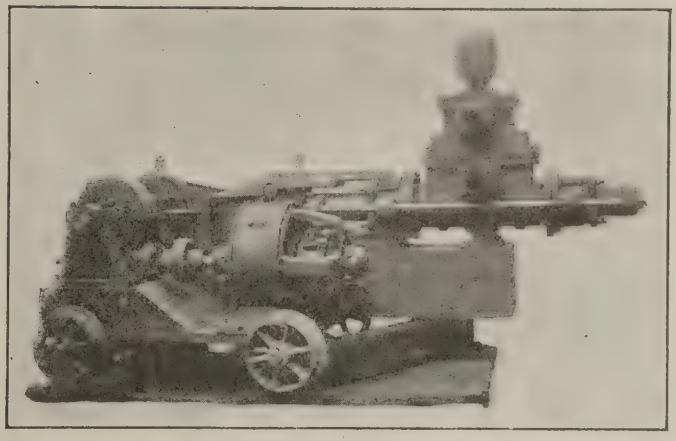
Motor-driven pumps may be operated by either direct- or alternating-current motors and may be of the reciprocating or centrifugal type. Fig. 4 shows a Goulds motor-driven triplex pump, and Fig. 5 shows a Goulds motor-driven centrifugal pump, both located in mines. These motor-driven pumps do not require starters, but can be directly connected to the power system. If power should go off and come on again, the pump will start up without requiring attention. These pumps are sometimes used in connection with a float switch which automatically starts and stops the pump at the proper time.



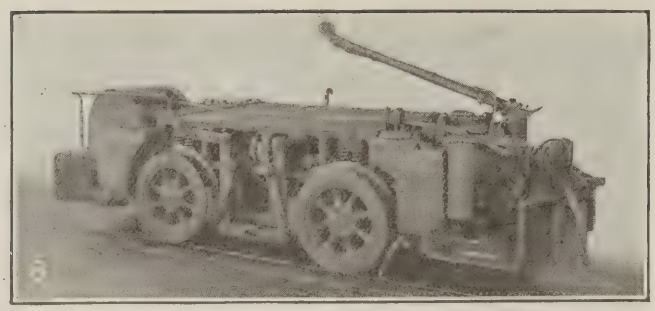


FIG. 6. PORTABLE MOTOR-DRIVEN PUMP

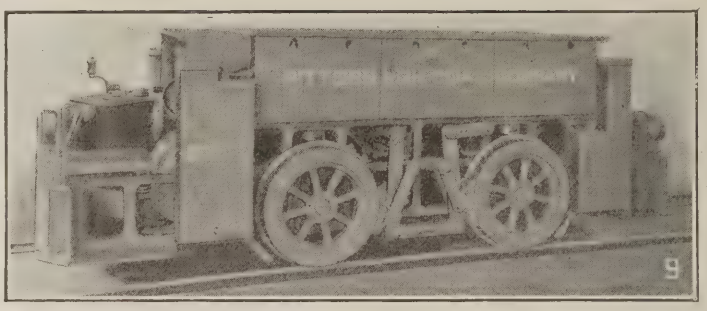

Fig. 6 shows a portable motor-driven pump which can be moved quickly to any part of the mine. This could not be done readily with a steam- or air-driven pump.

It is of course desirable that the ventilating system of a mine be thoroughly reliable, and there are many records showing steam fans in continuous operation

FIG. 7. FANHOUSE OF LEHIGH VALLEY COAL CO.

FIGS. 8 TO 10. THREE TYPES OF LOCOMOTIVES USED IN MINES
Fig. 8—Reel-type locomotive. Fig. 9—Storage-battery locomotive.
Fig. 10—A 35-ton three-motor locomotive

for long periods of time. Since the power required for ventilation is often a fairly large percentage of the total amount required at a mine, a fan should necessarily be economical in its use of power. An electric motor will in most cases be more reliable as well as more efficient than a steam engine. Fig. 7 shows a fanhouse of the Lehigh Valley Coal Co. The fan is driven by a 30-hp. motor and is controlled from a substation 1½ miles away.

It may be said safely that in the haulage system of a mine one of the most striking economies is obtained both in amount of labor involved and the expense of transportation by substituting electric power for animal or some forms of mechanical haulage. For gathering service, either the trolley type of locomotive with a reel or the storage-battery machine is rapidly replacing animals. One locomotive will replace two to four mules or horses, and since each animal not only requires a driver, but attendance when in the stable, a saving in labor will arise from its substitution. Fig. 8 illustrates a reel type of locomotive while Fig. 9 shows a storage-battery machine. For main haulage there is no comparison between the locomotive and animal haulage. This arises from the great distances traversed and the speed necessary. The capacity of locomotives for main haulage is becoming larger each year, until greater capacity can only be obtained by using two locomotives in tandem. Fig. 10 shows one of the 35-ton three-motor locomotives used in the Berwind-White mines at Windber, Penn. This is the largest locomotive operating inside of a mine in this country. The maximum length of haul is here close to 20,000 feet.

When vertical shafts or steep slopes occur, the coal must be brought up them by means of a hoist. The substitution of electrically driven hoists will effect a saving both in labor and cost of operation. A rather notable example of what can be accomplished by changing a hoist from steam operation is shown in a paper presented before the American Institute of Mining Engineers at its 1918 February meeting at New York, by R. E. Hobart, mechanical superintendent of the Lehigh Coal and Navigation Co., entitled "Economy of

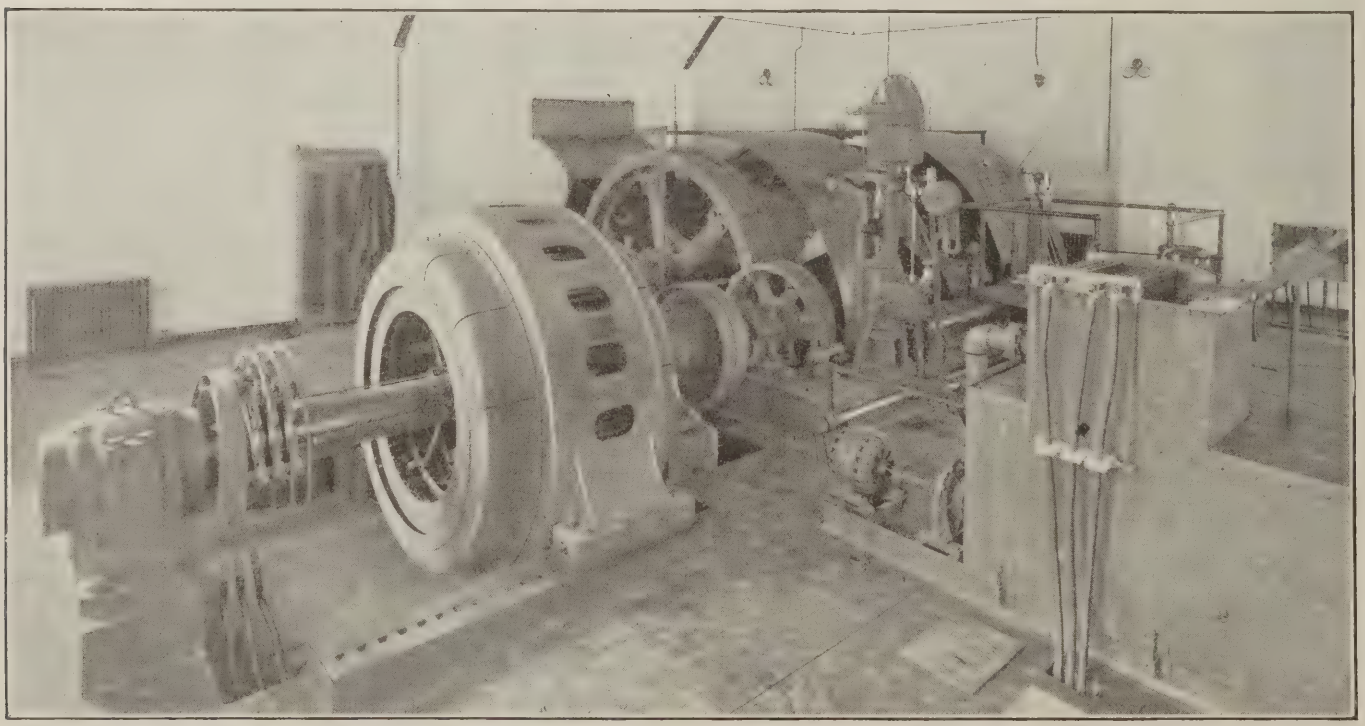

FIG. 11. HOIST OF THE INDUCTION MOTOR TYPE WHICH EFFECTED REMARKABLE ECONOMIES

Electricity Over Steam for Power Purposes in and About Mines." This paper shows that some remarkable economies were obtained, the results being based on operation of a year's duration. Fig. 11 shows the hoist in question, which is of the induction-motor type, having a continuous rating of 750 hp. with a capacity of 50 per cent. overload continuously. The mechanical parts of the hoist were furnished by the Vulcan Iron Works, of Wilkes-Barre, Penn., and the electrical equipment by the Westinghouse Electric and Manufacturing Company.

A great saving in labor inside of the mine can be effected by the use of small hoists of the winch type. These machines will take care of hoisting and lowering cars over steep grades where they cannot be economically handled by other means. The hoists are so simple that any miner, even though inexperienced, can operate them.

Where large hoists are involved and heavy peaks are objectionable, a direct-current motor, receiving its power from a flywheel motor-generator set should be employed. The largest hoist in America is of this type, and is illustrated in Fig. 12. This hoist is located in a large copper mine in the West. Two other machines for which the electrical equipment is a duplicate of the former have been installed recently. The hoist motor has a capacity of 2000 hp., continuously.

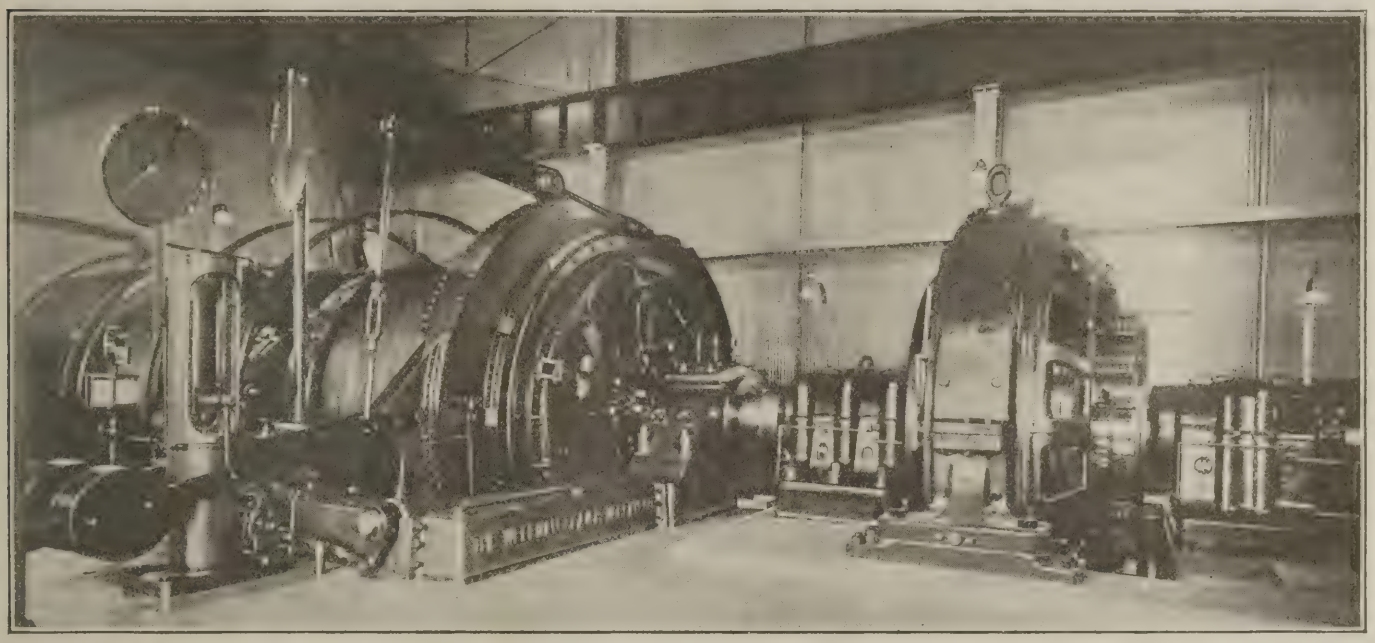

FIG. 12. DIRECT-CURRENT MOTOR DRIVES THIS HOIST, SAID TO BE THE LARGEST IN AMERICA

The greatest apparent saving in labor about a mine can be effected in connection with the actual digging of the coal itself. The use of coal cutters and loaders will greatly decrease the number of men required. Different conditions of roof, bottom, etc., often determine the type of machine best adapted to the work. The air puncher was a great improvement over the ordinary pick method of undercutting, and resulted in a considerable saving of men. The breast, longwall and shortwall chain-cutting machines, however, are the greatest labor-saving devices about a mine. One mining machine will easily do the work of from 20 to 25 miners and requires only two men to operate. Fig. 13 shows a shortwall cutting machine built by the Jeffrey Co. It is a compact piece of apparatus and will operate in low coal.

A suitable loading machine should effect a considerable saving in labor. This machine may be made fairly light and portable, and only requires that the coal be loaded on the front end.

A complete description of a machine that mines and loads coal without the aid of explosives was given in *Coal Age* of April 13, 1918. This machine should show the greatest labor saving of any device about a mine.

A new machine called a scoop hoist is being tried out in both anthracite and bituminous fields. It is especially adapted to low coal, and some bottom is taken up to enable a car to be brought up to the mouth of the room with the top of the car about level with the room floor. A V-shaped scoop is pulled into the room by means of a tail rope, and when pulled out drags a certain amount of coal with it. The scoop is pulled over a sort of gang plank and deposits the coal in the car. When pulling coal out the scoop really works something like a snow plow pulled backward. A small reversing motor is required, and the device should replace several loaders.

One of the greatest advantages to be obtained by the use of the foregoing devices is that instead of a large number of unskilled men working in the mine there will be a comparatively few experienced men who realize the dangers of mining and will exercise the care necessary to prevent accidents and explosions.

The mine telephone has proved a great labor-saving device. When trouble occurs, and a telephone is available, machinery can be set in motion at once to right the difficulty. The superintendent, mineboss and electricians can keep in touch with various parts of the mine, so that the efficiency of operation can be kept at its highest.

After the coal leaves the mines there is still a large field in which labor can be saved in its handling. Most of the large users of coal have good facilities for taking care of it when received by cars or boats. Until recently the docking facilities on our seaboards have been

inadequate, not only entailing the use of considerable labor but causing needless delays. Some large and expensive coal docks have recently been put into commission on the eastern coast of the United States, and the saving effected in labor and time has been great. This subject has been quite fully covered in an interesting article published in *Coal Age* of May 18, 1918, by C. L. Packard, of the General Electric Co., entitled "New Methods of Hauling Coal Electrically."

New ways and means are being constantly devised to facilitate the handling of coal from the face in the mine to the ultimate consumers. It is significant that

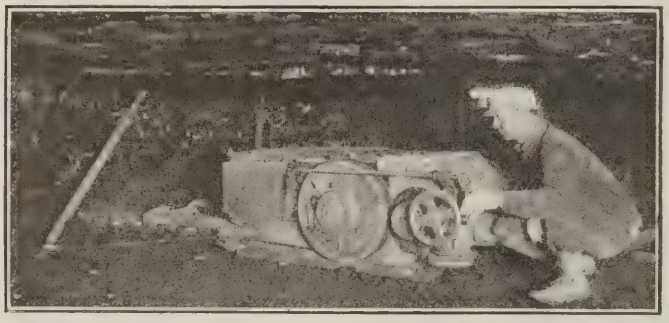

FIG. 13. JEFFREY SHORTWALL CUTTING MACHINE

in practically all cases these new methods utilize electric power in some form or other to accomplish a saving in labor, which at the same time leads to a considerable saving in expense.

It is strongly suggested that the operator keep a more accurate record of the time lost by men and the costs of operation. In no other way will the advantages and economy of electrically driven mechanical equipment be as readily apparent. The large manufacturers of electrical equipment are always ready to help the operator in making a study of his special conditions, including tests of his entire plant and securing the data necessary to enable a complete report to be made, analyzing the conditions in detail, and showing the economies and savings effected by the use of electrical equipment.

Haulage and Loading Equipment

By E. M. Mackie
Syracuse, N. Y.

It may safely be said that in most mines more coal can be cut than there are facilities for taking out, also that the labor entailed in removing the coal is much greater than that expended in the actual cutting. This means that any device or arrangement that will make easier the loading and hauling of the coal will result in a great reduction of time and labor.

When the loaded cars have been delivered to the entries, their haulage, even for miles, is a comparatively simple proposition, but the getting of empty cars placed and loaded, and loaded cars removed from rooms and back-reaches, also the delivery and loading of coal from low rooms, is a far greater problem than the straightway haulage in the entries. Because of the conditions of service any apparatus used in this work must be readily portable, simple, efficient and as nearly foolproof as possible.

The application of electrically operated haulage engines or hoists to this class of coal-mine operations has now passed the experimental stage. The Pneumelectric Machine Co., of Syracuse, N. Y., has successfully developed a line of haulage devices that is well worthy of consideration, in connection with interior haulage and loading problems.

The following brief description of various pieces of such equipment and their application may be helpful to mine men, especially in these days when labor is scarce and sorely needed in the coal fields.

The single drum haulage engine or room hoist is a handy little machine that has been called the greatest saver of man power in a mine. Weighing approximately 950 lb., with no rope on the drum, and occupying a space of only 28 x 38 in. and 26 in. in height, there are but few locations in which this amount of space is not available.

Its capacity may be stated as being 1500 lb. rope pull at a speed of 100 ft. per minute, and this may be ap-

FIG. 1. THIS SINGLE-DRUM ROOM HOIST SAVES CONSIDERABLE MAN POWER

plied to any kind of haulage within the capacity of the machine. Maximum drum space will accommodate 900 ft. of ⅜-in. steel cable. A view of this hoist is shown in Fig. 1.

This hoist may be mounted on a truck as a portable unit. A diagram of the application of such a mounting is shown in Fig. 2. This machine may also be provided with two drums instead of one. It can readily be seen that with this type, cars loaded or empty, on variable grades, may be easily handled and are always under control.

Quite recently this type of hoist has taken a prominent part in the development of methods for hauling

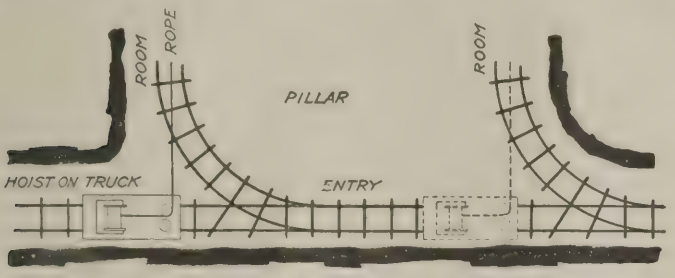

FIG. 2. DIAGRAM OF HOIST MOUNTING

and loading coal from rooms to entries or headings in the anthracite fields. In this work two systems are being used and developed. One is known as the pan delivery system, and the other as the scraper loader system.

In the pan delivery system the coal is loaded on the pan at the face, by hand, and then hauled to the entry or heading to be dumped into a car. After dumping, the pan is hauled back to the face; the forward and backward haulage is accomplished by a double-drum hoist.

In the scraper loader system the scraper is hauled along the face, gathering a scoop load of coal, which it then conveys to and dumps into a car in the entry or heading. After dumping, the scraper is hauled back to the face. With this system hand loading is eliminated.

Besides the aforementioned haulage devices, there is another effective piece of apparatus designed for mounting on a locomotive, its dimensions being such that when so mounted it does not extend beyond the overall dimensions of the locomotive framing. This device is known as a gathering attachment, and its use on a locomotive provides it with a "long arm" by means of which it is able to reach out and gather in cars from locations that without the help of the gathering attachment could not be served by this machine.

Another member of the same family is the capstan. This is a rugged and foolproof haulage device, capable of quickly saving its cost wherever there is a hard pull needed. It weighs only 450 lb. and can be put in a space of only 24 x 30 in. This device is well known to many readers. It is essentially a cathead or vertical winch equipped with suitable driving apparatus.

The old hee-haw mule for a long time took care of the interior haulage problem, and where he could not be used man power took his place. But today men are scarce and we need old hee-haw above ground behind our boys at the front, so the mines now have to depend on mechanical mules. Fortunately, these have been developed to suit the exigencies of mine service, and every day sees them being adapted to new uses.

Legal Department

AVOIDANCE OF ILLINOIS WORKMEN'S COMPENSATION ACT—In order that an employing coal operator can avoid liability to pay compensation for an injury under the Illinois Workmen's Compensation Act, he has the burden of proving, not only that the Industrial Board had been notified that he elected not to be bound by the act, but also that the injured employee had received a copy of such notice, or that the notice had been duly posted as required by the law. (Illinois Supreme Court, Barnes vs. Illinois Fuel Co., 119 Northeastern Reporter, 48.)

COMPUTING AWARDS UNDER MICHIGAN LIABILITY ACT—Deceased had been employed by defendant coal company for several years, excepting a short interval within the last year preceding his accidental death, which occurred in the course of his employment. Held, that an award against the company in favor of the surviving widow should be computed on the basis of the decedent's average daily wage earned after his reinstatement, and not on the lower wages earned by him within the year but before the strike. (Michigan Supreme Court, Brown vs. Central West Coal Co., 166 Northwestern Reporter, 850.)

ACCIDENT AND DISEASE AS CONCURRING CAUSES OF DEATH—If accidental physical injury concurs to hasten an employee's death, a previously diseased condition of his body will not relieve his employer from liability for payment of an award to the employee's dependent relatives under the Indiana Workmen's Compensation Act. Hence, where the immediate cause of a miner's death, through rupture of his aorta, was a strain in moving coal, his dependents are entitled to an award notwithstanding the fact that a diseased condition of the aorta may have been a concurring cause. (Indiana Appellate Court, Indian Creek Coal and Mining Co. vs. Calvert, 119 Northeastern Reporter, 519.)

CONTROL OVER INTRASTATE RAILWAY PRACTICES—Interpreting statutes of Nebraska, the Supreme Court of that state decided in the recent case of Rivett Lumber and Coal Co. vs. Chicago & Northwestern Railway Co., 167 Northwestern Reporter, 570, that where there is attempted discrimination between persons and associations by a railway company, and one is not allowed reasonable and equal terms, service, facilities and accommodations, the courts have jurisdiction to grant redress; but that where the question raised is whether a community or locality is properly served by the railroad company, as where the company refuses to construct side tracks or switches to serve industries, such question should be presented to the State Railway Commission for determination.

MINE OWNER'S LIABILITY CONCERNING MINE FOREMAN'S NEGLIGENCE—The business of making or directing excavations for overcasts in the roof of haulways or air courses in a West Virginia coal mine as the operations progress, for properly ventilating the mine, and of making the places of work safe, is by the laws of the state devolved upon the statutory mine foreman, and his negligence in the performance of these duties, unless he is authorized by the mine owner to represent him in other ways incompatible with his statutory duties, as in the employment and discharge of miners, can not be imputed to the owner and render him liable for personal injuries sustained through such negligence. Authority of the mine foreman to represent the mine owner beyond his statutory duties must be proved either by express authority given, or by such open, apparent and notorious acts and conduct on the part of the mine foreman that it is evident they must have been known to the owner of the mine, and approved by him. Proof of one or two isolated instances is not sufficient to establish authority by implication. (West Virginia Supreme Court of Appeals, Strother vs. United States Coal and Coke Co., 95 Southeastern Reporter, 806.)

The Emergency and Clean Coal

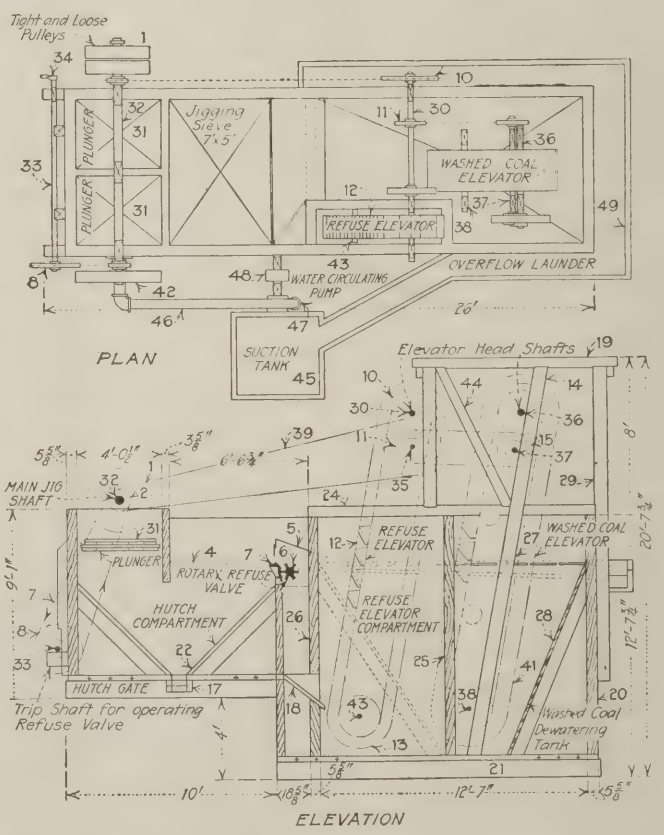
By G. H. ELMORE
Philadelphia, Penn.

SYNOPSIS—*An increase in the quality of output is as essential as an increase in output. The older washeries were an aggregation of mechanical equipment, heavy, cumbersome, and at best somewhat disappointing in operation. More modern machines have been devised that are smaller, lighter, are controlled automatically, and give a much more uniform product.*

THE bituminous operator who appreciates the present situation, who is called upon for maximum production, who knows full well the prices he must pay for everything in the line of mining equipment and all materials that enter into plant construction, who knows the scarcity of labor and its high wage, will doubtless shrink at the thought of entering on any elaborate plan of plant construction, the object of which is solely to improve the quality of his coal.

The history of last season's production has in it several things other than coal that are black. Leaving out the story of the failure of the railroads, cold homes, and industries without fuel, perhaps the one consideration that impressed the average user of bituminous coal the most was the poor quality of the product furnished to him. *Coal Age* has repeatedly and in a forceful way called to the attention of the bituminous operators the necessity of remedying this condition. The arguments used need not be repeated here.

Economically and morally, it is a crime to ship dirty coal. By dirty coal I mean coal that contains more impurities than can reasonably be expected to be removed from it. There are certain well-known methods of preparing dirty coal for the market. When these are employed, they produce results that are satisfactory both to the consumer and to the Government.



I cannot believe that the operators who, last season, shipped trainloads of waste material did so through choice, but that in a situation of bewildering stress it was more or less the force of circumstances that compelled such shipment. Since then there has been time for reflection, time to take stock of all questions entering into the problem, and it must be true that the moral sense of the bituminous coal operators of this country will prevent them from repeating the practices so prevalent last season. In the last analysis, it is the moral questions involved in these great issues that shape their course.

All laws of conduct are founded on questions of right and wrong. Economic and other considerations take second place. There can be no doubt nor argument on the question of right and wrong involved in shipping and selling as coal material that is not coal, and which could, with reasonable care and expenditure, have been eliminated. If this practice is continued during the coming season, it should be regarded by both the people and the Government as a crime.

What then, under present conditions, can the operator be properly expected to do to right this matter? There are many reasons why the operator cannot be asked to incur large expeditures for elaborate plant construction. The Government's need for the construction materials that would be required and the great scarcity of labor are in themselves sufficient causes for this, but the real reason lies in the fact that such expenditure and elaboration are not necessary. For it will be here shown that with an exceedingly simple plant, which can be erected and put in commission at moderate cost, these much-desired results can be obtained.

It will be understood that what is here outlined pertains chiefly to the production of bituminous coal for fuel purposes and has no relation to the preparation of coal for metallurgical use, such as blast-furnace coke, etc. The whole discussion is further simplified by the fact that only the slack and the nut need be considered. When these two sizes are removed, the remaining product can easily be hand-picked.

Under the present stress for maximum production, there frequently may be found sources whereby considerable tonnage can be secured other than from the

FIGS. 1 AND 2. PLAN AND CROSS-SECTION OF A COAL-WASHING JIG

regular run-of-mine, such as clearing up of old dumps made in the days when coal was cheap and when much good fuel was consigned to them, the cleaning up of old workings, or even the handling of certain portions of the bed that have heretofore always been discarded. Any or all of these may become sources of

considerable revenue and production. In many cases they can be treated in the same plant with run-of-mine, slack or nut, combined making a good market product.

The modern coal-washing plant is a decidedly different affair from its predecessor. As in everything else pertaining to coal mining, the last few years have

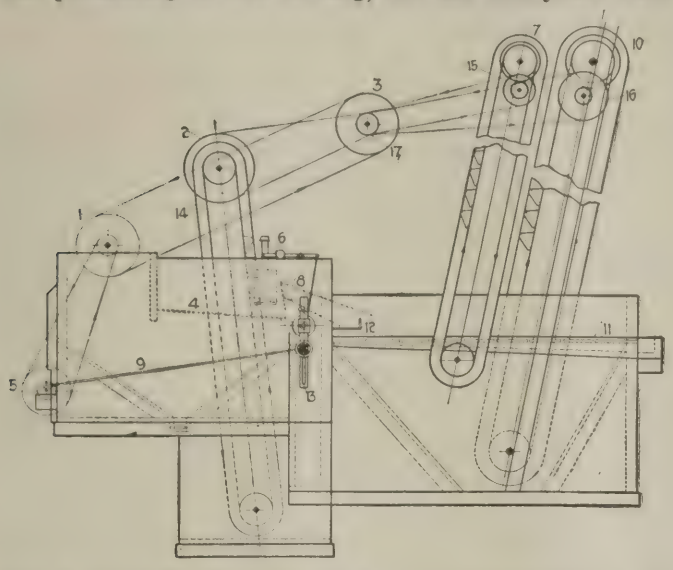


FIG. 3. SIDE ELEVATION OF A TWO-COMPARTMENT JIG

wrought marvelous changes in the practical application of this art. It was not long ago that the operator who contemplated building a coal-washing plant took on a real burden—more or less a nightmare, a vision of sprockets, chains, drags, elevators, belts, pulleys and shafts, to say nothing of leaking tanks, slop and mire; and all in such bewildering confusion that frequently it was difficult to crawl through it. But this was only the beginning. The first cost of such a plant was great, and the upkeep was still greater.

Contrasted with this, the modern coal-washing plant is an orderly, simple, highly efficient piece of construction. It is probably a fact that it does not contain over one-third the amount of machinery formerly used for handling a given tonnage. This is principally due to the fact that the flow sheet has been much simplified, the unit capacity of the machines tripled, and automatic appliances provided which guarantee highly efficient operation and uniform results. The suggestions that follow are designed to meet the emergency brought on by the war. They involve a still greater simplification, but without reduction in efficiency; and while the application is not universal, it will apply to a large majority of the operations where a better preparation of the slack and nut is demanded.

Let us assume that the problem is to wash 50 to 60 tons of slack coal per hour. Figs. 1 and 2 show a plan and cross-section of a jig with its refuse and washed coal elevator and its water circulation pump all in a self-contained unit, driven by one belt applied to a pulley on the main jig shaft. This machine has a jigging sieve 7 ft. wide and 5 ft. long. The jigging stroke is provided by two plungers acting in unison, and the refuse is removed by the automatic jig control later described.

It will be noticed that the whole apparatus, which has a capacity as stated above, is housed in a single tank construction. The jig tank, the washed coal dewatering tank and the refuse elevator compartment are all one structure, made of 2 x 6-in. lumber surfaced on all four sides and spiked down flatwise with all the corners and intersections alternately overlapping, and with two strands of candle wicking between each layer. These strands are placed both in the horizontal and vertical joints. That portion of the tank in which the jigging machinery is placed is further braced by heavy rods extending down through the tank construction, and across from side to side through the hutch in both directions, making a rigid, durable, leak-proof jig tank. The iron work alone on this jigging machine weighs about 13,500 lb. This does not include the weight of the elevators or the circulating pump.

The place occupied by this entire unit is so small that the building which covers it is correspondingly inexpensive, particularly as this building does not have to support the weight of any transmission equipment. The size of the dewatering tank for the washed coal, combined with the manner in which the water is removed from this tank for re-use by the overflow launder extending entirely round its outside, insures good settling effect of the fine coal and water for re-use in the jigging machine that carries little fine coal in suspension. The re-use of this water lessens the demand for a fresh supply to be added continuously to the circulating system. The amount of fresh water required is equal to the moisture in the wet coal and wet refuse as it leaves the plant.

These products, as they come from the dewatering elevators, will carry from 15 to 20 per cent. more moisture than did the raw coal when it entered the jigging machine. Hence, when, say, 40 tons per hour of raw coal is going through this plant, there will be consumed from 6 to 8 tons of fresh water, depending on the amount of moisture in the raw coal; or from

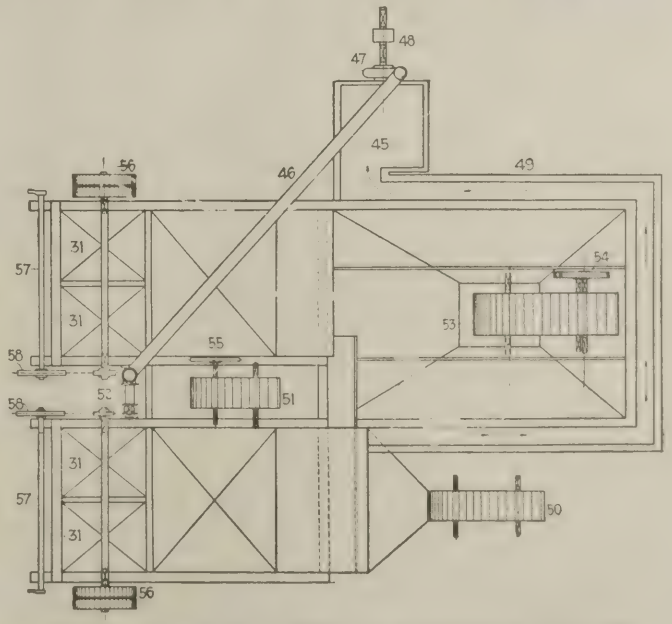

FIG. 4. PLAN OF A TWO-COMPARTMENT JIGGING MACHINE

25 to 33 gal. of water per minute. This amount of water can be provided at almost any mine without serious difficulty or expense. In many cases this equipment can be set up close alongside the tipple, allowing the slack from the screens to shoot directly into the raw-coal feed bin placed just behind and above the jig-

ging machine. Where the screens are too low to permit this, a short drag or belt conveyor will carry the slack on an incline and discharge it into the feed bin.

The equipment can be so set that the refuse and the washed coal elevator will discharge into bins over the main track, or the refuse can be taken to a convenient dump by a small car or other means.

The point to be emphasized is this: Here is a highly efficient automatically controlled coal-washing plant, having a capacity of from 400 to 500 tons of slack coal per day of eight hours. It is fitted with heavy and durable equipment, both in the jigging machine and in the elevators. This plant, even under present conditions, can be erected and put into commission at a comparatively small expense, can be operated by one man, yet its building requires the minimum of labor.

Let us now assume that the problem is to handle from 50 to 60 tons each of slack and nut coal. Figs. 3 and 4 show the plan and elevation of such a unit.

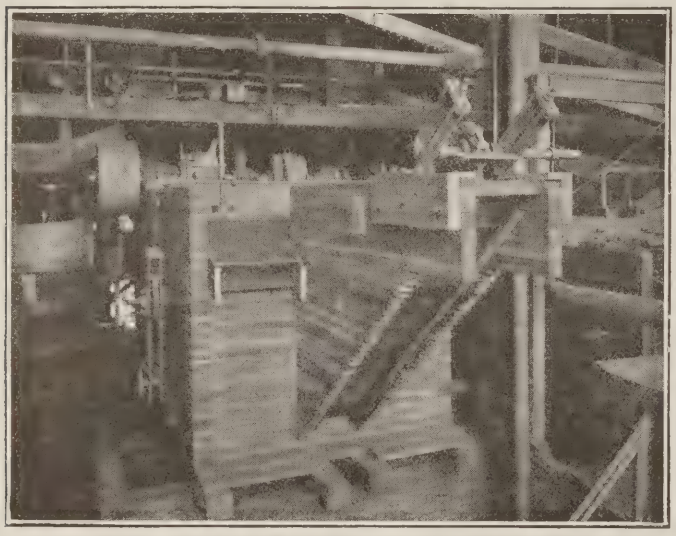

FIG. 5. COAL JIG TANK DURING CONSTRUCTION

The plan shows a two-compartment jigging machine, each compartment of which can be operated separately from the other, with a compartment between them containing the common refuse elevator serving both sides and discharging to the rear of the machine. The slack is taken care of in the same manner as provided in the first problem, by the dewatering washed-coal elevator set in the large washed-coal tank, the overflow from which provides the circulating water for jigging purposes, as mentioned above.

The nut coal, after passing with the water beyond the overflow of the jig, runs down over a perforated screen covering the entire width of the jig. Here it is dewatered and passes directly into the washed coal nut elevator, by which it is discharged into the washed coal nut bin over the railroad track. This elevator, because the coal is already dewatered, is not provided with perforated cups. It travels at about twice the speed of the washed coal slack elevator.

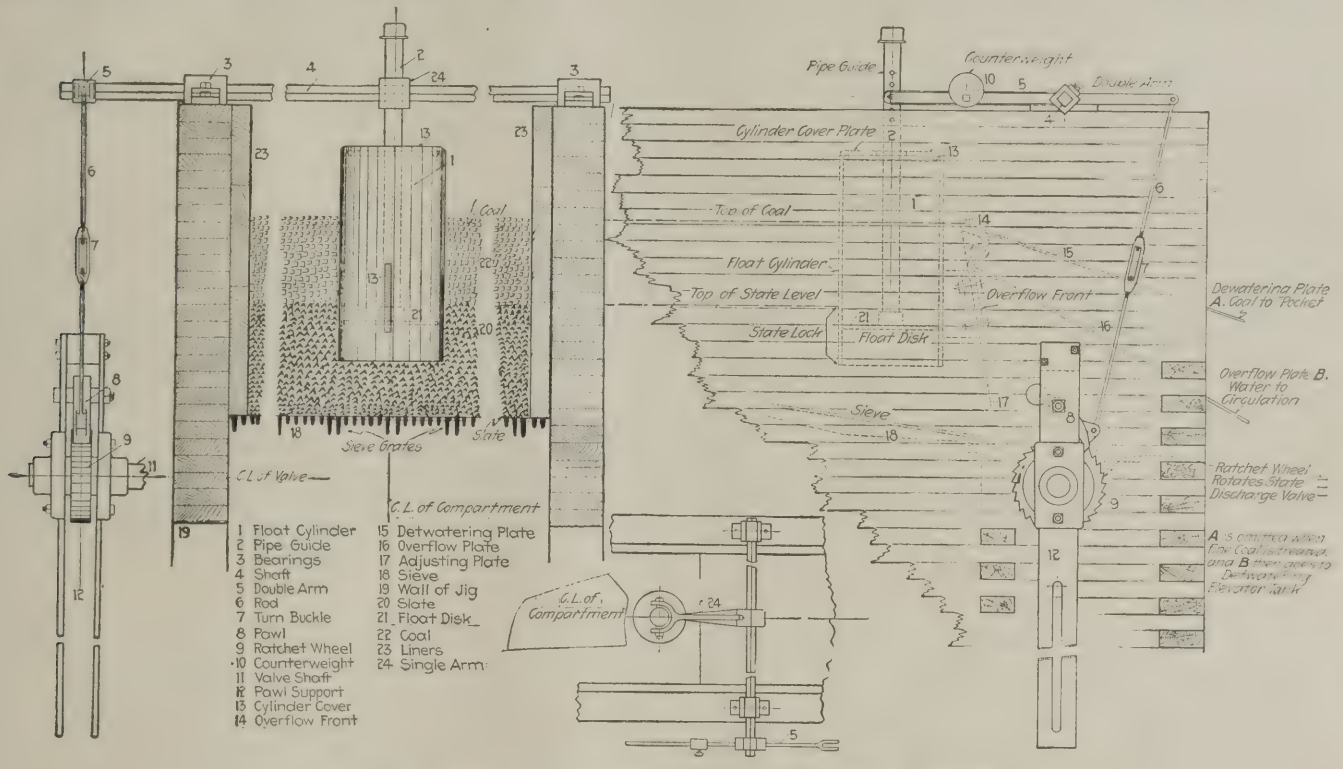
The water which passes through the overflow screen from the nut jig falls directly on the steel plate underneath, as shown. From here it is discharged into the cross-launder, which carries it into the slack dewatering tank, mingling with the water and coal coming from the slack jig. It will be noticed that any fines that may come over with the nut coal will go through the screen and into the slack coal, where they belong. In this manner, therefore, the nut coal is thoroughly rinsed and all fines are removed from it before it reaches the nut coal elevator.

This plant, although having twice the capacity outlined in the first problem, because it is built double, can be placed quite similarly; and inasmuch as the transmission equipment rests on timbers, which themselves are supported on the tank construction and all the equipment is driven from a single main shaft resting on these timbers, the plant maintains its unit construction and unit drive as before. It is, however, entirely flexible, each side having independent operation if desired, and each automatically controlled, insofar as the removal of the refuse is concerned.

Let the third problem be to handle from 100 to 120 tons of slack only per hour. The construction would be the same as indicated in Figs. 3 and 4, except that the washed coal elevator tank would extend entirely across the front of the two jigging machines. The washed coal elevator would have sufficient capacity for handling both sides of the machine, and the nut coal elevator would be omitted.

It is obvious that other sizes than those mentioned can be handled on the two constructions as shown, such as the nut size only on the first or on both sides of the second construction.

To illustrate more clearly the form of tank construction used, reference is made to Fig. 5, which shows only the tank of one of these jigging machines as it is being constructed in a large anthracite coal breaker in Pennsylvania. The view is taken from above, and the different layers which form the walls and partitions as they are spiked together flatwise are clearly revealed.



The history of the development of the automatic control for jigging machines would make interesting reading for one interested in the jigging art. It has taken fully a dozen years to bring it to its present simplified and highly efficient form. Beginning as a rather complicated, electrically controlled device, it is now built as shown in Figs. 6, 7 and 8.

Fig. 6 shows the section transversely across the jigging compartment, just behind the overflow plate 14, and directly through the float cylinder 1. Fig. 7 is the side elevation of the jig, showing that portion of the tank and equipment where the overflow plate, the automatic control device and the mechanism for actuating the refuse valve are located. Fig. 8 shows a plan of the jigging compartment.

To the overflow front casting 14 is bolted the float cylinder 1. This is 10 in. in inside diameter and about 24 in. high, open at both ends. The bottom end is placed at a distance from the jigging sieve of 3 or 4 in. below the level of the top of the layer of slate which it is desired to maintain on the jigging sieve. By slate, reference, of course, is made to all the refuse material that it may be desired to remove from the coal. On top of the layer of slate will accumulate the layer of clean coal, to a height and thickness up to the top of the overflow front 14, where the clean coal with the water used in jigging will overflow onto the plate 15. For treating slack this is made solid, but for jigging nut or coarser sizes is perforated, allowing the water to go through and accumulate on plate 16.

Inside the float cylinder is the flat cast-iron disk 21, carried at the lower end of the pipe guide 2. Attached to this pipe guide is the arm 24, which at the other end is fixed to the square shaft bar 4, carried in the bearings 3. At the end of this shaft, which extends out over the wall of the jigging machine, is the double arm 5. One side of this arm carries the counterweight 10 and the other end is connected with the rod 6, in such manner that it can lift the pawl 8. This pawl is a part of an oscillating mechanism mounted on the shaft 11, which forms the stem of the rotating valve for drawing off the refuse. This valve extends entirely across the width of the jigging bed, which in this particular machine is 7 ft. wide.

The construction of this valve is shown at 6 in Fig. 2. The refuse comes through the opening below the adjusting plate 17 and lies against the flights of this

FIGS. 6, 7 AND 8. DETAILS OF THE JIG CONTROL DEVICE

rotating feeder type of valve. As this valve rotates, the refuse is withdrawn from the jigging sieve and falls on a sloping board in the compartment underneath, whence it runs by gravity to the refuse elevator or other drag equipment for removing it from the jigging tank. The constant oscillating motion of the arm 12 is given by the crank and connecting-rod as shown in Figs. 1 and 2, the crank being driven from the main jig shaft by suitable sprockets and chain. Keyed to the valve stem 11 is the ratchet wheel 9.

It is evident that when the pawl is down and the arm 12 is oscillating, the ratchet wheel 9 is rotated in the direction of the arrow as shown, and that when the pawl 8 is raised and not allowed to mesh with the teeth, no rotation of this ratchet will take place, inasmuch as the bars 12 simply ride on the shaft 11 and are not keyed to it.

The automatic control of the rotation of the refuse valve is therefore entirely a matter of permitting the pawl to engage the teeth and rotate the valve whenever the level of the slate or refuse on the jigging sieve has reached the point determined as maintaining the proper thickness of this bed of slate, and conversely to stop the rotation of the valve and hence the withdrawal of refuse whenever the level of the top of the bed of refuse has been lowered to the desired point. This is readily accomplished by the equipment shown and in the following manner:

As the refuse accumulates on the jigging sieve, it will find its way up into the float cylinder 1 from the bottom end and will impinge on the bottom side of the float disk 21. At each stroke of the jigging plungers this float disk will receive a corresponding impact from the refuse as it is driven upward from below, and the whole structure of the float disk, the pipe guide, the arm and counterweight will have an upward and downward movement with a few degrees of angular rotation of the shaft 4. This upward and downward movement is conveyed to the pawl 8, which really oscillates on the bolt holding it in position between the arms 12. By adjusting the counterweight 10 to properly balance the effect of the upward pressure of the slate on the bottom of the float disk, an equilibrium is quickly produced by which this float disk is maintained at a certain level in the jigging bed. Whenever additional slate comes on the jig, the float disk will be raised within the cylinder, and this will lower the connecting rod 6 and permit the pawl to engage the teeth of the ratchet 9, instantly rotating the valve and removing the refuse through the orifice 17.

This lowers the level of the refuse in the jigging sieve and permits the float disk to sink to a lower level, when the pawl will again be lifted to a height not permitting it to engage the teeth of the ratchet, and the withdrawal of refuse will be instantly stopped. When nothing but clean coal comes on the jigging machine, or when the feed is entirely stopped, the pawl will

accordingly be entirely disengaged and no refuse will be removed. This condition is not temporary in nature, but will continue no matter how long the jigging machine is run.

It is remarkable how accurately this simple device controls the level of the top of the refuse bed in the jig. No matter how the rate of feed may vary, either in tonnage or quality, the level of the top of this slate bed is maintained almost at a given point throughout the entire shift, making it impossible for clean coal to find its way through the orifice 17, or for the refuse to accumulate in the jigging sieve high enough to go over the overflow plate at 14. Thus uniform products of clean coal and clean refuse are guaranteed. With the former methods of operating jigging machines these products depended entirely upon close attention given by the jig operator.

Formerly the jig operator's only method of determining the conditions in the jigging bed—that is, of knowing how high the slate level had accumulated—was either to run his arm down into the bed of coal and find the top of the level of the slate, or to use some device like a bottle on the end of a broom stick and by practice learn to determine this level by the "feel" as he lowered this bottle through the coal as the machine was being operated.

More frequently neither of these tests was faithfully practiced, and the regulation of the machine, insofar as the refuse removal is concerned, was controlled by his observation of the two products coming from it. Whenever slate was noticed coming with the coal, more refuse was withdrawn. Whenever coal was noticed coming with the slate, less refuse was withdrawn, and hence the adjustment of the machine was sometimes permitted to become entirely wrong before steps were taken to make it right.

With the automatic device, as here illustrated, the adjustment is kept correct all the time. The level of the slate bed is maintained where it should be throughout the entire shift, and this without the attention of an operator. This device is now in operation on hundreds of coal jigging machines, handling both bituminous and anthracite coal, and has proved its utility beyond the shadow of a doubt.

COAL CONVERSATION

Overheard Between Two Carloads of Coal in a Railroad Yard

A "Coal Age" subscriber has forwarded the following contribution, with the explanation that one whose ears are attuned to catch the conversation of inanimate things could have overheard the dialogue, which took place between two carloads of coal in a certain railroad yard not so many nights ago. We believe that Pennsy and Micky have uncovered a few truths that should be made evident to each miner and each operator. Every ton of coal loaded into a car should be loaded on honor.

"Hello, Pennsy, where are you going?"

"Don't know," answered the carload of coal addressed. "Where are you bound for, Micky?"

"Oh, I'm to help a lot of our boys get to France," and the load of coal in the P. Mc.K. & Y. car shifted proudly.

"Is that so?"

"Yes, sir."

"Did you pass all your examinations?"

"I sure did. I've been inspected, found O. K., and now I'm going over."

"So that's what makes you so bright and cheery, eh?"

"Yes, sir. I certainly am glad. But what makes you look so glum and downhearted, Pennsy? Are you sick?"

"No, I'm not sick. I'm just as strong and healthy as you are, but I've been rejected; and it's no fault of mine." What sounded suspiciously like a groan came from the direction of Pennsy.

"Well, then, what is the matter?"

"You know," answered Pennsy, "there's a kind of binder or band in me in my natural condition, and I'm sure I can't help that."

"Why, that shouldn't matter," responded Micky. "The same thing is true of me."

"No, it can't be the same," said Pennsy, "or they would have condemned you, too. They turned me down the first thing. How did you pass if the binder is in you?" he inquired curiously.

"Oh, it isn't in me now," answered Micky. "Before I was loaded into the car every bit of binder was picked out of me. I feel so much lighter now, and I know I'll burn much better. You see," continued Micky, after a pause, "that binder is a bad thing. It gets into the grate bars and clogs the grate, and it hinders the firemen from getting up steam. If Uncle Sam wants to get the Kaiser," wound up Micky, enthusiastically, "it is going to take the best that's in us."

"I wonder why they didn't treat me the same way," said Pennsy plaintively.

"Well, I'll tell you some of the reasons," answered Micky, waxing loquacious. "In the first place," he began, "the miner is trying to make all the money he can, and he's discovered that the more weight the more money——"

"Why don't the boss stop them?" interrupted Pennsy.

"Well, he is somewhat excusable," said Micky.

"How do you make that out?"

"You see," replied Micky, "if the boss says anything, the miner goes to another mine to work; so the operator says, 'Don't be too strict,' because he, too, is after the money. The more weight the more money," and Micky chuckled. "Another thing," began Micky; "the men are being rushed to make a large production, and of course the miners are not particular. In goes the binder, and you are condemned."

"Well, then," asked Pennsy, "why don't Uncle Sam get after those fellows? They certainly are not true to him."

"He is getting after them, but not strong enough. You see, Pennsy, Uncle Sam is asking the people to conserve food and substitute other things, so I think these fellows are trying to make dirt take the place of coal. Here comes the engine," he broke off, "and I guess we will have to part."

"Good luck to you, old man, you're going where you'll be honored; but as for me—say," he whispered, "I'm not alone in this. There's another load of coal that came from a stripping mine. You ought to see that."

Increased Production by Use of Modern Mining Machinery

BY MINER RAYMOND
Tiffin, Ohio

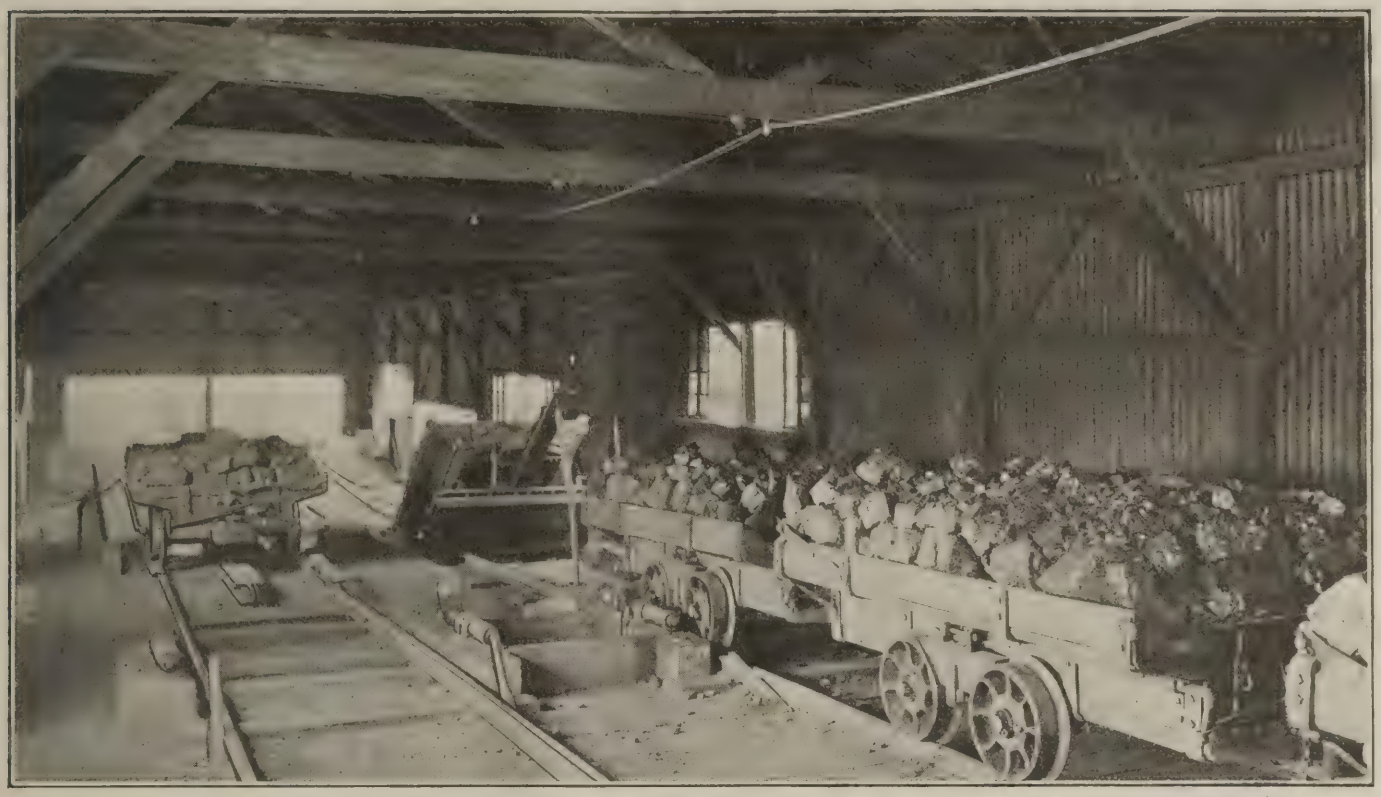


FIG. 1. LABOR-SAVING DEVICES AT TIPPLE—AUTOMATIC STOPS AND CROSS-OVER DUMPS

THIS article offers an opportunity for serving our country by giving some actual facts to prove that the installation of modern tipple equipment is of vital necessity to coal production, by assuring a greater coal tonnage with fewer laborers. The coal situation is one that materially affects every phase of our national life. The humble householder stores a few tons of coal so that his youngsters can warm their shins around the old "base-burner" before going to school on a cold winter's morning, and the question is equally absorbing to the United States Government, which must provide thousands upon thousands of tons for the bunkers of our ships whether they be the magnificent fighting vessels of our navy or the new cargo vessels whose keels first moved down the ways on the Fourth of July.

With this universal interest in mind, and facing the absolute necessity for a production of 75,000,000 tons of coal over last year's tonnage, and with over 100,000 miners who may be taken for military service, it hardly seems necessary to point out to coal operators that their patriotic duty is to raise the efficiency of all phases of coal production to the highest degree. Any neglected opportunity to raise productive efficiency by the installation of modern tipple equipment is an unpatriotic act no less than if the operators knowingly refused an opportunity to contribute of their means to the financial part of the Government war program, as expressed in Liberty Bonds and War Savings Stamps.

But there is another phase of the question which should not be overlooked in discussing matters of this sort. The increase of efficiency of production in a coal tipple yields benefit not only to our nation in its time of need, but also to the operator himself. It is almost beyond question that every mine owner, manager or tipple superintendent is interested in anything that would yield him profit, especially when the benefit is a direct contribution to the war plan; but still there seem to exist a few to whom proofs are necessary even when the benefits are so seemingly self-evident. In one case in which a plant owner was shown how the installation of a simple device could reduce his unloading costs by using only one man part of the time instead of two men all the time, he refused to purchase the equipment on the ground that he would not know what to do with the one man's time when the unloading device was idle Such a statement is hardly believable at a time when labor is so scarce in all lines of business, but it actually happened in June, 1918.

Taking the question from the selfish standpoint, with the knowledge that the selfish standpoint in this instance is of marked benefit to the national need, we find further excuse for adopting this program when the Government itself places a premium on prepared coal. Even before war times came upon us, the expressions of satisfaction over the increased efficiency of modern tipple equipment were so numerous that even a hasty collection of them

could easily make this number of *Coal Age* resemble a booklet of patent medicine testimonials. Analyzing such a collection would readily lead to the reduction of all methods of increasing tipple efficiency into three groups.

The first is the reduction in the actual cost of production by delivering the same tonnage with fewer men. Among many such examples there are found two which are typical. One of these is where an elaborate system of trackage was replaced by simple trip-handling equipment, including automatic stops and cross-over dumps, Fig. 1. Coincident with the starting of this new equipment five men were removed from the payroll. This was prior to 1916, and today these men could be put to work in another part of the company's property. In another case a single long flight conveyor costing less than $10,000 performs the work of six men who formerly cost the company, at the very least, $6000. The item of $6000 a year would pay the interest, upkeep and power consumed on an installation costing many times $10,000.

The second means of increased efficiency is the production of a larger quantity of coal at the same operative cost. Cases of this kind are perhaps the most numerous of any. There are many coal companies which, for years, worked a seam of good quality with their entire tipple equipment consisting of a simple dump, a set of bar screens and a couple of loading chutes. I know of one case where an installation of this kind was replaced with a complete modern equipment, including shaker screens and loading booms for the egg and lump. One hundred tons a day was the output of the old plant, while the new installation took care of more than 250 tons per day, with the same number of men in the tipple, and the coal produced commanded a greater market price. There was also a minimizing of breakage in the soft coal and a consequent increase in percentage of lump secured from mine-run.

This last part of the advantage gained in this particular case properly belongs to the third item of increased tipple efficiency, which mainly relates to the production of a higher quality from the same origin and with the same, or decreased, operating costs. It is invariably true that the better mechanical equipment shows results whose direct influence in high market standing yields fancy returns on investments and operating costs. This statement is made by a man who has visited and analyzed a large number of coal installations and has been familiar with the history of the trade for a good many years. One tipple superintendent who has been in the game for years, in speaking of his new tipple which replaced an antiquated structure, said of his tipple machinery, "With the use of it we are better able to prepare our product than ever before, with a minimum amount of labor."

One advantage of modern tipple equipment in the production of bituminous coal is the marked reduction of breakage, which is a direct result of the efforts of tipple designers along this line. At every stage of progress of coal through the tipple it has been the aim of competent engineers to avoid dropping coal; one of their most notable improvements was the introduction of the loading boom (Fig. 2) which carries the lump or egg into the car and avoids the fall which was an indispensable feature of the old-time curved loading chute. One mine owner writes: "We have been worrying for years over the breakage of block coal from the original chute. The loading boom wipes out any drop . . . there is absolutely no breakage."

These three roads to tipple efficiency are closely interwoven at every stage of tipple operation, and it might be of interest to follow briefly a hypothetical path of the coal through its various stages from the mine opening to the railway track. This is merely an imaginary case, but it is based on individual features

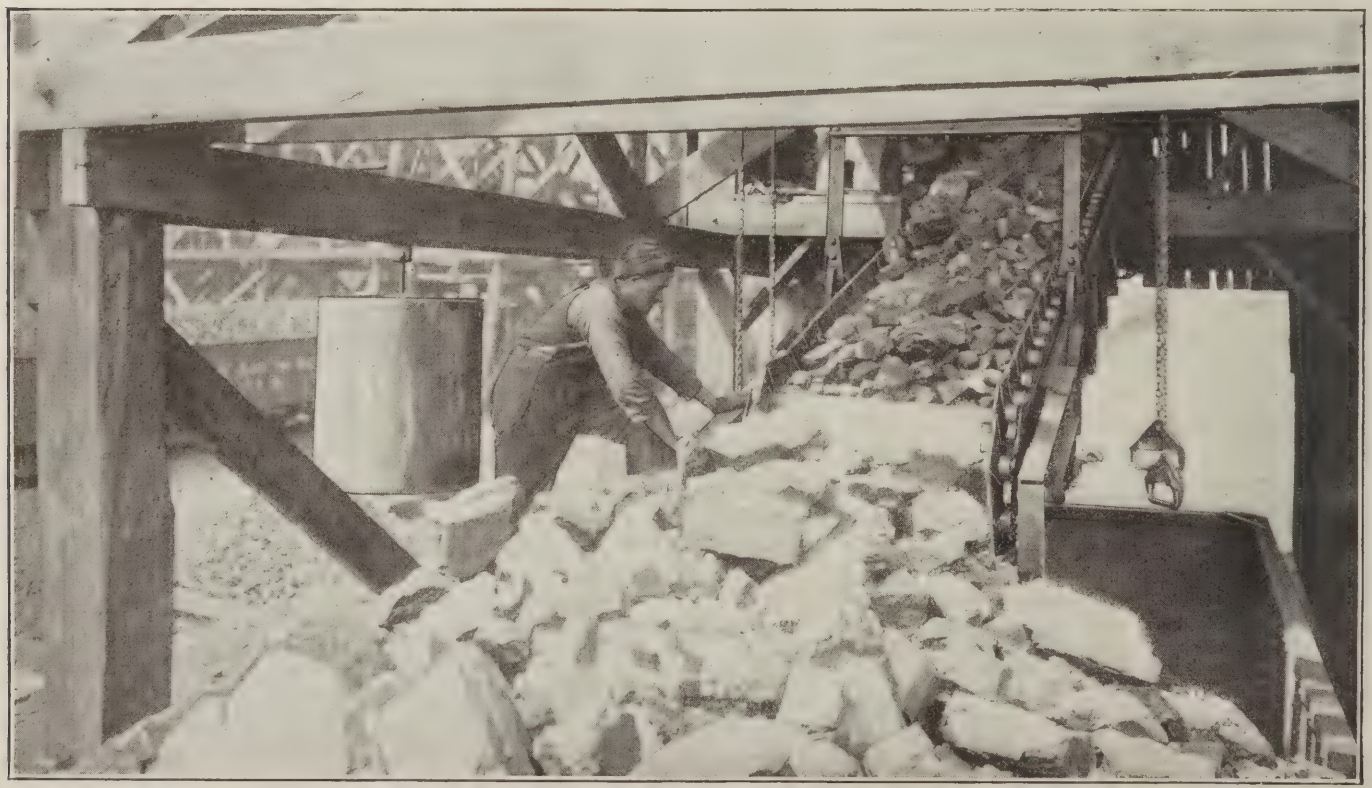

FIG. 2. BREAKAGE OF COAL AVOIDED BY LOADING RAILROAD CARS WITH LOADING BOOM

FIG. 3. CONVEYOR FROM MINE TO TIPPLE

common to many operations. Let us suppose that the mouth of the drift is high up on the hillside, with the railway passing at some distance away in the valley below. Beginning at the drift mouth, we find today that electric locomotives have replaced the old-time animal power.

At the dumphouse, at the top of the incline, there is a tripmaker and feeder with steel car haul and grades handling cars in quantities and at a speed impossible to even a large crew of huskies. A modern cross-over dump discharges the coal into the hopper, from which we find that the coal is no longer taken down a double-track incline to the tipple, but a modern retarding conveyor takes the load from the dump hopper and carries it down the hillside almost without attention, Fig. 3. In this one point—in the travel of the coal down the hill by the modern retarding conveyor—labor costs have frequently been more than cut in two. Of course, there are slopes too steep for retarding conveyors, but wherever they have been found practical they have dispensed with at least one man at each terminal.

In the tipple itself we find the retarding conveyor ceaselessly discharging its load into the hopper, from which an automatic feeder gives the screens a constant and steady flow. With the retarding conveyor there is no uncoupling or dumping of cars at this point and no laborious pushing the filled cars over the dump or pulling the empties out of the way. From here on, the shaking screens carefully remove all of the slack so that none is now carried over into the cars with the lump, as was formerly the case with the old bar screens. The coal is cleanly sized and breakage minimized by the careful design of screen slots and careful engineering in the driving mechanism, which assures a steady forward movement. The lump and egg travel to the cars over the loading booms, the advantages of which previously have been suggested, and before they pass down the incline into the cars all impurities can be easily and quickly removed on the picking table.

There are a thousand and one modifications of tipple design. These, of course, have marked differences from the outline noted. However, it is hoped that this will serve to suggest a few of the many points in modern coal tipple equipment which, taken together, constitute machinery's contribution toward the production of more coal and better coal with fewer laborers—a valuable contribution not only to the success of the operator himself, but also to the higher and better cause, in support of which a million of our boys from every walk of life have crossed the seas to fight.

Coal Carbonization

By M. Meredith
Liverpool, England

The war has thrown many burdens upon gas engineers, not only on account of the great shortage of labor, but also by reason of the heavy demands for benzol, toluol and other products of prime importance in the manufacture of explosives. The gas engineer, in normal times, has looked upon his coal-carbonizing plant merely as a means of turning out the highest yield of gas possible per ton of coal treated; and whereas he has received considerable sums for his tar and oils, these have been mere incidentals in the one important business of gas production.

At the present time, while a high gas yield is of prime importance in order to meet the demands for gas for various purposes (which have multiplied and are still increasing owing to war conditions), yet many established practices have had to give way in order to obtain the required quantities of byproducts. High gas yields have been associated with low tar yields, for the tars have been degraded by high temperature, in order to convert them into gas of a permanent character.

At the Macclesfield gas works, as a result of careful and progressive experiments, and now of considerable extended commercial use, it has been found possible to increase the gas yield per ton of coal carbonized and at the same time obtain largely increased yields of tar and ammoniacal liquor. The latter is an important matter from an agricultural point of view, as artificial fertilizers are urgently needed. This result, the importance of which cannot be overestimated, has been attained by injecting steam into the base of the continuously operating vertical retorts, so that blue water gas is generated there. This high temperature gas, rising through the incandescent and also the partially heated coal, not only proves efficacious in removing the last traces of gas from the coal, but also distills or washes out the tarry matter contained in the semi-carbonized fuel before the tar has been subjected to the extreme temperatures which degrade it by destructive distillation.

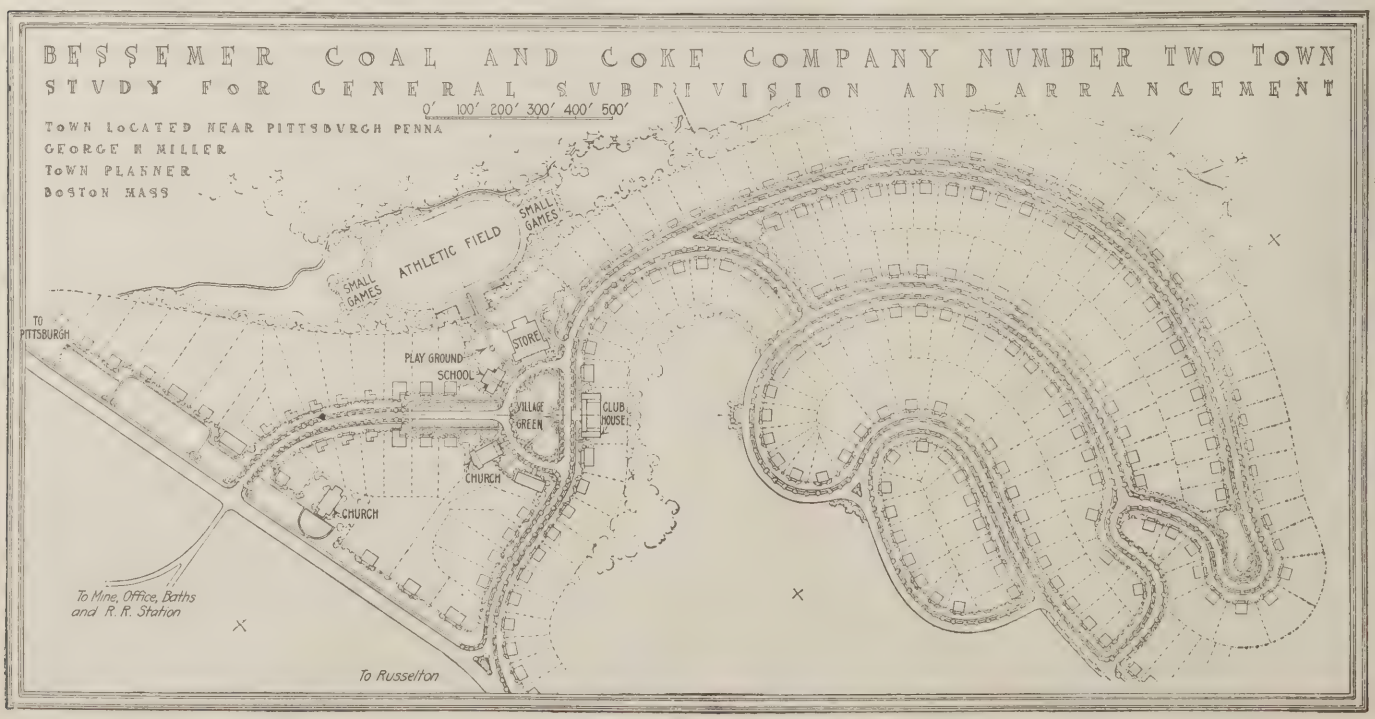
The following comparative figures are illustrative of some remarkable results which call for further attention and study:

	Average for Year Ended Mar. 31, 1915	Test on Aug. 13, 1917
Gas made per ton treated	12,049 cu. ft.	15,477 cu. ft.
Calorific value—gross per ton treated	530 B.t.u.	508 B.t.u.
Coke per ton treated	13.6 cwt.	13.36 cwt.
Ammoniacal liquor per ton treated	25.3 gal.	32.68 gal.
Tar per ton treated	10.9 gal.	16.61 gal.

No deterioration in the retorts has been noticed as the result of steaming, and scurfing has been reduced to a minimum.

DEPARTMENT OF HUMAN INTEREST

Plan Your Town as Carefully as You Would Your Plant



BY GEORGE H. MILLER
Town Planner, 6 Beacon St., Boston, Mass

Most mine owners decide for themselves how much money they will spend on a mining town, and in most cases that sum is just sufficient to cover the cost of the least number and least expensive sort of houses, the necessary water-supply and a type of outside toilets that will suffice. These, and possibly a company store, are constructed as quickly as possible in straight rows on the nearest available drained land, the mine is put into operation, coal is turned into cash and you have a mining town.

As time goes on and the mine pays, there often arises justification for the erection of a church. The owner listens to the representations of his resident officials and workmen, or himself begins to take a sentimental pride in the source of his income, and it is not unusual to see the church erected, and possibly a school, or both. Many are the club-houses now being built as afterthoughts, in old mining towns throughout the country, and here and there a hotel, playground and sidewalks, shade trees and groups of shrubbery are being added that were never dreamed of when the town was first built. Often, also, many additional houses are required for which sites are hard to find, and after these various features have gradually been developed in this short-sighted manner the eventual final aspect of the town as a whole is one of heterogeneous confusion and disorder—for things, architectural, mechanical and horticultural which are designed for domestic use invariably express the guiding motive by which they are planned.

To eliminate the wasted time, energy and cost of construction, use and maintenance resulting from this method of procedure and to gain greater economy, utility, convenience, safety and beauty in mining towns, it is becoming common-sense practice to study in advance some of the reasonable possibilities which the future may present. It is becoming customary to engage town planners who make a specialty of this work. They are asked to offer suggestions and advice based on their years of training, observation and experience, and to devote their faculties and talents to studying out these problems with some degree of nicety and foresight.

The town planner does not try to dictate what the town shall contain at the start; he does not try to influence the amount of initial financial outlay. He may be an idealist, but if he knows his business he is primarily an economist. He takes the conditions as he finds them and is guided by the wishes of the owner. His motive is to apply his experience and art to producing the best immediate and future results out of the crude material given him. The value of the town planner's service is in saving the misdirected efforts of the owner, his engineers and other officials, and in producing a more efficient town without increasing costs. There are plenty of examples even of the smallest mining villages which prove that such service is needed and succeeds.

A VILLAGE LAID OUT TO FIT BOTH NATURE AND THE NEEDS OF THE INHABITANTS

TOPOGRAPHICAL MAP SHOWING HOW GENTLY GRADED SITES WERE CHOSEN FOR ROADS AND HOUSES

The town planner customarily inspects the property, confers with the owner and helps to select the site of the town. Then he outlines the necessary surveys and how they shall be gathered, probably by the company engineers. Over the survey the town planner makes notes of his observations in the field and then prepares a study for general subdivision and arrangement of the town. The study is accompanied by a report completely defining all ideas represented therein, and with sketches showing the character of all cottages and other buildings and directions pertaining to their construction are submitted to the owner for criticism and suggestions, often at the outset being sufficient for execution under the oversight of the company superintendent or engineers. The cost of such studies is usually about one per cent. of estimated cost of construction, or from five to ten dollars per acre of land included in the study, the amount being definitely agreed upon at the preliminary visit of inspection. Detailed construction plans may be furnished by the town planner or he may act in advisory capacity only, passing upon all plans and keeping in constant touch with those who take in charge the routine of the detail work.

Buildings in a mining town which are public or quasi public by the nature of their use are the store, church and school, club-house, hotel, and possibly baths and office building, garage and a few better types of residences for officials and skilled men. The club-house as center for social and physical recreation may become the general community house, combining the functions of a hotel, club-house and baths or used in turn as school, church and theater. Some of these buildings may never be necessary, a thing that can be determined with considerable accuracy in advance, but when there is the slightest possibility that they may be called for in the future it is better policy to reserve desirable sites where they may serve their full purposes than be obliged to locate them in inconvenient, out-of-the-way places. It is desirable that most of these buildings be designed in one appropriate simple style of architecture with proper relation to each other, and be grouped in a formal arrangement about a central open space, or public square, thus creating a miniature civic center.

Community spirit may develop and justify outdoor recreation facilities, an athletic field with grandstand, a children's playground with apparatus, or a park comprising a waterfront or a tract of land which either affords views or is more valuable for beauty than for use. Most mining towns being in the mountains the first thing a town planner looks for in studying the general scheme of arrangement is a sufficient area of nearly flat land to be reserved for an athletic field and center of outdoor recreation. If there be only a limited amount of such land and it be appropriated for the first cottages built, just because that is the easiest way, then the idea of an athletic field must either be abandoned for all time or a site graded at considerable expense. The shape assumed by the area of flat land in a location convenient for a town center may suggest curved boundary streets on which cottages or other buildings are very attractive as seen from each other across the green. Flat spaces usually being comparatively low, although not necessarily damp, are often near the railroad or mine works, and therefore when used as a mine center are in the path of travel, and so naturally inviting and easy of access. The improvements at such a location and the activities taking place there can be made picturesque and interesting as seen from the encircling rows of houses situated on the surrounding hillsides.

It is seldom necessary or desirable that streets of a mining town shall be straight, or be arranged in gridiron fashion. When town sites consist of mountainous rolling land the streets should fit the topography with pleasing curves and easy gradients, and afford natural and attractive positions for the houses and other buildings. The streets should accommodate directness of travel and be located and designed for a given amount and kind of travel. Streets of this kind are less expensive to build, to use and maintain.

Two types of houses come under consideration in properly housing unskilled labor. First, there are houses erected solely to fill the needs of men with families, the most desirable kind of men in any village. Such houses should accommodate a single family only. They should be detached, semi-detached or built in groups, according to races of employees that are to be accommodated and according to the nature of the land to be used as a town site. Second, there should be dormitories or barracks for men without families, such buildings to have a mess hall, shower baths and other communal features and a separate and sanitary room for each man, however small and bare it may be. The most modest cottage can be given the aspect of a home if the same amount of thought is devoted to designing its appearance as to reducing its cost. The town planner knows the fundamental principles of cheap cottage design, the things that cost and the things that without extra cost make the cottage more useful, comfortable and attractive.

The modern mining town is built simultaneously with the mine works, and as the mining spreads and the employees increase in number, so also the community expands. In planning a mining town the layout of streets and alleys, the lines of all kinds of conduits and fences, the saving of top-soil surfaces for gardens, the placing of trees and other planting, the arrangement of all visible features, the scheme of a community center, and the location of houses of different types and outhouses, are designed on paper in advance of construction or growth and as one homogeneous and complete, correlated and compact scheme, provision being made in advance for later expansion. This is the procedure that makes physically possible the model mining town.

If We Would Be Safe, All Must Help

By S. D. Otis

Bay Shore, Long Island, N. Y.

In recent years much good work has been done toward making the mines of our country safe. But mine operators can never make their plants safe if the men do not coöperate with them. Mine operators, as well as all other employers of labor, are yearly coming to a fuller realization of the advantage of taking care of their men. They adopt safety devices of all kinds, provide good housing conditions and employ company doctors to safeguard the lives and the health of their miners. But in face of this work on the part of the operator, are the miners doing their share?

In many, many mines, I have seen evidence of the fact that while operators are trying to provide safeguards for their men, the employees ridicule and ignore these precautions and so make them of little value. There are several classes of men who busy themselves in undoing the good work that the mine owner tries to do for the safety of his men. About the worst of these tamperers is the would-be humorist who changes the meaning of warning signs and thus endangers not himself but his fellow workers, whom the signs are meant to warn against injury or death. By changing a few letters, here and there, these sign defacers produce an effect which they consider funny; but, on the other hand, by their action they make the safety signs useless.

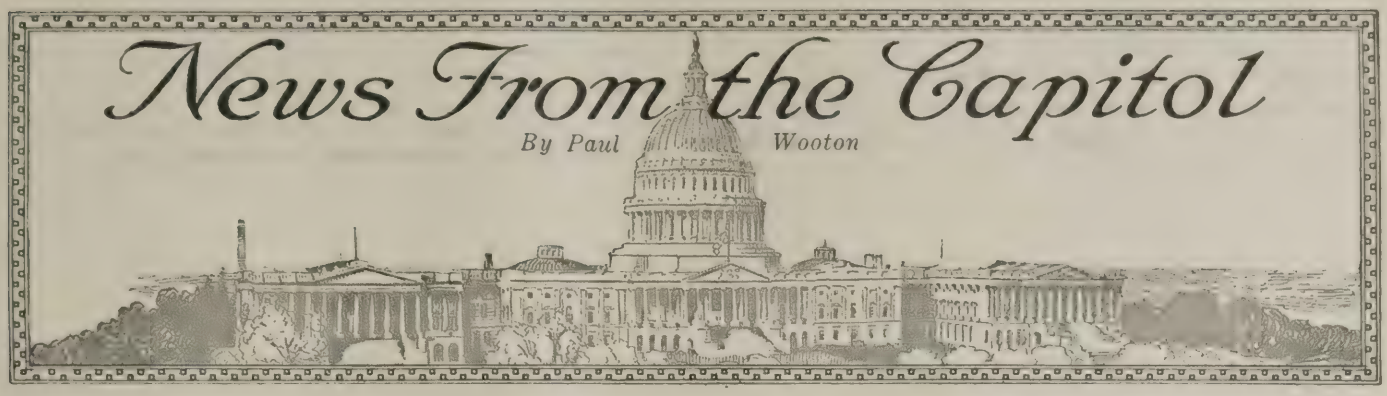
I recently saw in a coal mine a good example of the defacing of a sign. The sign originally read thus:

DANGER! DANGER! DO NOT WALK UNDER WIRE

By marking out some letters and marking over others the sign was made to read:

GER MAN DO NOT TALK DER WAR

Clever? Yes, but criminal! The man presumably drew some pleasure from his smartness, but I wonder if that pleasure would in any way compensate him if he should see one of his fellow workers struck down by the electric current from that wire? Every mine has in it warning signs, but the real meanings of nearly all of them have been destroyed by thoughtless, misguided persons.



Another mine worker who endangers his own life and the lives of the men who work with him is the one, usually young and reckless, who plays tricks with the electric current in the trolley line. He stands on a board to partially protect himself and touches the trolley wire with a dampened newspaper. Any man he touches with his free hand receives a sharp shock, and the practical joker's happiness is complete. This trick may often do no harm, but there are cases on record where it has had fatal results for both men.

Yearly many men are injured and killed by falling in the way of a moving locomotive or of a trip of cars traveling down grade. Most of these falls are caused by sheer carelessness in crossing tracks. The victim trips on lumps of coal and slate left between the rails or falls when stepping negligently on ties and rails made slippery by the leakage of oil from cars. In mines where modern equipment is used, of course, this wastage of oil does not occur; but where old-fashioned cars are still in service extreme care should be taken to remove the dangers of slipping and of fires resulting from the presence of oil-soaked ties.

Serious fires and explosions occur in the most carefully watched mines because the men do not coöperate with the management in taking the most ordinary precautions. It does not seem possible that in a gassy mine practical mining men provided with electric lamps would carry and use matches, but I have seen the open flame of a match in a dozen dangerously gassy workings.

Any man who is careless in handling explosives should be classed as a dangerous person and not allowed to work with, or near, any kind of explosives. Recent articles in *Coal Age* have taken up in detail the proper methods of using all forms of explosive material, and such materials should be handled in absolutely no other manner than that so set forth. Saddened widows and cripples in every mining town can testify to the importance of using intelligence and care in working with explosives.

Mine operators and mine-operating companies should not cease in their efforts to make their mines safe for their men, but the men themselves can do much to help and much to hinder the good work. They should constantly guard against foolish, life-threatening acts and should make it unpleasant for any man who exposes them to danger.

Government to Operate Coal Barges

Coal-carrying barges are to be operated by the Government between the Alabama coal fields and the Gulf of Mexico. An announcement to that effect has been made officially by the Director General of Railroads. The transportation line in the Alabama coal service is to be operated in conjunction with the freight-carrying lines, which are to be put on the Mississippi River between St. Louis and New Orleans.

Coal already has been transported down the Alabama rivers to the Gulf in considerable quantities, but the opposition of the railroads and the inadequate equipment have retarded the development of water outlets to the Alabama fields. Since the coal can be handled into New Orleans on the same barges that bring it down the river, a large tonnage is expected to move by the new route as soon as regular service starts.

With the assurance which goes with a Government undertaking, Alabama operators will now provide the necessary terminal and handling facilities so that they will not be dependent entirely on railroad cars, the scarcity of which hampered their operations greatly last winter. The Government line will begin operation with existing equipment, but plans already have been drawn for improved barges and tug boats.

To Speed Up Movement of Coal Cars

Sluggish movement of coal cars, both loaded and empty, brought forth a formal order last week from A. H. Smith, regional director of the eastern district of the United States Railroad Administration. In the order, he declared it to be "of vital importance that our efforts be redoubled to secure an improved circulation of coal-loading equipment. This is of such importance that we feel justified in asking you to agitate this vigorously in all operating offices so that we may be able to make a suitable improvement."

No Coal for Use of Country Clubs

Wood apparently will be the popular fuel at country clubs this winter, as a result of an order from the Fuel Administration forbidding the use of other fuels for such places. The order is not absolute, as the Fuel Administration will issue licenses of exception when the state administrator will certify that the fuel can be spared and that it is not against the public interest to grant such a permit. Peat is included with wood as a proper fuel, when neither requires the use of railroad transportation facilities.

Permits Small Shipments of Steel for Essential Civilian Uses

To avoid delays in the filling of small orders of steel urgently required for essential civilian uses, the War Industries Board has decided to permit shipments which are not in excess of five tons without request for priority. This is expected to relieve the coal-mining industry of much annoyance, as a considerable portion of their needs for iron and steel products is in small lots.

Appoints District Representatives

J. D. A. Morrow, on his recent trip to the West, appointed the following district representatives: George D. Kimball, Denver, for Colorado; J. Van Houten, Raton, for New Mexico; W. B. Innes, Great Falls, for Montana; Moroni Heiner, Salt Lake, for Utah and Wyoming. Mr. Heiner will be assisted by A. D. Pierson, of Salt Lake City, who is the assistant district representative for Utah, and by D. H. Pape, of Ogden, who is assistant district representative for Wyoming.

Inspection Leads to Coal Conservation

One week's inspection of power plants at Pittsburgh resulted in the conservation of 81,000 tons of coal, according to a report to the Fuel Administration made by Thomas R. Brown, the administrative engineer for the Pittsburgh district. State administrative engineers have been appointed as follows: H. J. Meyer, Minneapolis, for Minnesota; Henry Adams, Baltimore, for Maryland, and Horace S. Hunt, Jackson, for Michigan.

Weekly Production Statistics

Production figures for the week ended July 6 are as follows: Bituminous coal, 10,259,000 tons; anthracite forwardings, 31,493 cars; beehive coke, 579,000 tons; byproduct coke, 502,666 tons. With the exception of byproduct coke, production in each case shows a marked decrease as compared with the preceding week. This is due almost entirely to the observance of the July 4 holiday.

Quite contrary to expectations, the average production per working day, during the week under review, held up to the high average of the week before. This was made possible by the return of practically all operatives on July 6. In previous years it has been difficult to obtain more than half of the daily average production

on the day following July 4. Anthracite shipments fell off 25 per cent. as compared with the week preceding. This was larger than had been anticipated.

The average production for the five working days of the week at the beehive coke ovens fell off sharply during the week under review. In the principal Pennsylvania producing districts, which had an output during the week of 348,178 tons, 20.6 per cent. of operating capacity was lost due to the shortage of yard labor. Both coal and coke cars were available in quantity. Despite the holiday, the byproduct output continued to forge ahead and now has passed the 500,000-ton mark. The ovens are operating at more than 90 per cent. of maximum capacity under ideal conditions. The principal loss of output was due to repairs to plants, with labor difficulties ranking next.

The figures referred to in the foregoing are estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Necessity of Conserving Coal

Nothing less than the vivid realization that the coal situation this winter threatens to be more serious than was the case last winter caused the Fuel Administration to take the drastic step of cutting off all fuel from breweries. While the coal supply available for use this winter will be intelligently distributed and no recurrence of the confusion of last winter will take place, the requirements of the war industries are mounting so fast as to make it clear that there is not enough for all.

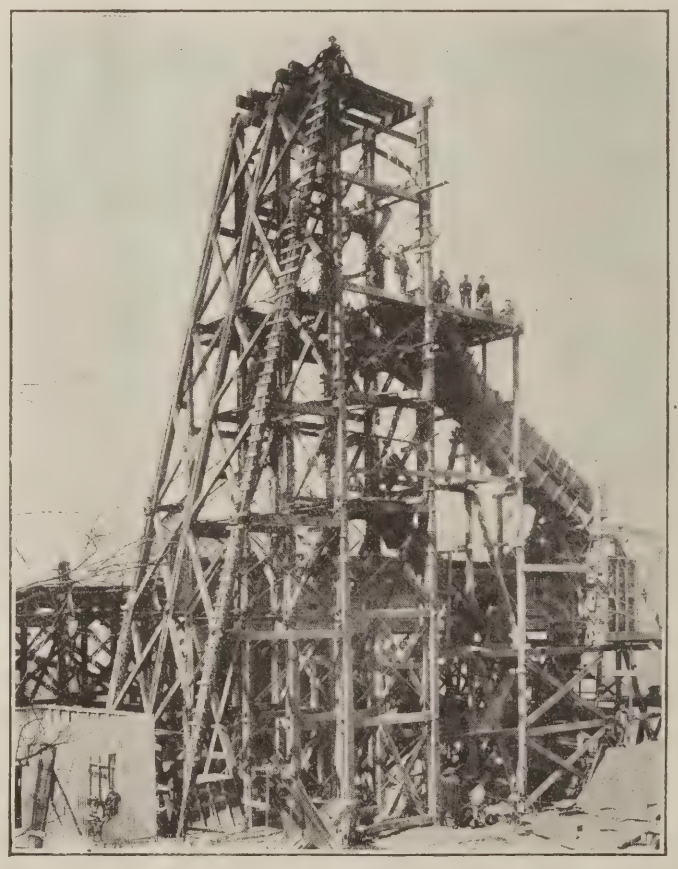
The work of supplying the domestic consumers is going ahead more rapidly than had been anticipated, and there will be no inconvenience on the part of householders if they practice conservation. The Fuel Administration is being given prompt coöperation by the consumers, who now are reporting their requirements. This information is being tabulated as fast as received and is giving a more intelligent view of the situation.

It was not the cutting off of the fuel from the brewing industry which has caused the concern throughout the country reflected in every mail to Washington, but it is the uncertainty as to how far this policy will extend. Some are anticipating that 50 per cent. of the non-war industries will be down before spring from lack of coal. The Fuel Administration is indulging in no predictions as to what will happen to the non-war industries, but every effort is being made to bring to the attention of the public the necessity of conservation.

The incident which precipitated the brewery order was an announcement from the Railroad Administration that 200 additional carloads of coal could be handled through the New England gateways each day. New England's schedule already is much behind, but so closely was the consumption following after production that it was found necessary to divert supplies destined for non-war industries in order to fill the 200 additional cars each day.

Each industry is to be studied by a committee headed by Clarence M. Woolley, so that curtailment can be made in the most intelligent manner possible. The other members of the committee are Edward Chambers, P. B. Noyes, Theodore F. Whitmarsh, Edwin B. Parker and Edwin F. Gay.

Limits Use of Gas Coal in Northwest



Gas coal moving into the Northwest must be distributed only to manufacturers of gas and to operators of byproduct coke plants. An order to this effect was made necessary on account of the fact that gas coal was being used for other purposes, when the greatest difficulty is being experienced in procuring ample supplies for byproduct coke ovens and gas plants which supply domestic users.

Brief Washington Notes

An entire floor of the new Commercial Bank Building, Washington, D. C., is to be occupied by the National Coal Association. One of the features of the new offices will be the directors' room. It will be large and particularly well furnished.

J. D. A. Morrow, S. L. Yerkes, A. W. Calloway and J. B. Neale, of the production division of the Fuel Administration, attended the operators' meeting at Fairmont, W. Va., to confer with regard to the best manner in which the coal from that section can be distributed.

Evans Woollen, federal fuel administrator for Indiana, is to have charge of the Bureau of State Organizations of the Fuel Administration during the absence of Walter E. Hope, who has been compelled to return temporarily to his office in New York.

HEADFRAME OVER NEW SHAFT OF CONNELLSVILLE BASIN COKE CO., ROCK FORGE, W. VA., BEFORE COMPLETION

The structure is of timber, 95 ft. high, and handles coal into the shaker and breaker of the old tipple in the background. The old tipple still serves the drift mines, but ultimately all the coal will come through the shaft. The shaft is 130 ft. deep, and concrete lined throughout. It is 10 ft. 10 in. by 24 ft. in the clear, with three compartments, two for hoisting and one for air, pipes, etc. The cage guides are bolted to the steel I-beam buntons.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Provost Marshal General Crowder denied on July 17 that a special order had been issued placing anthracite workers in a deferred classification for purposes of the military draft. In denying a contrary story that had appeared in the Washington press he said that no change had been made. The matter is still left to the discretion of the local boards. He understood that these boards were placing coal miners in deferred classes.

The other news regarding labor seems this week to center around prohibition. Suddenly in the country over national abstinence is being talked by people who have not been given to discussing it hitherto—at least not favorably. The National Coal Association advocates this war measure in a communication to Dr. Garfield. There is no temporizing in its statement; it wants prohibition to be nation-wide; it wants it to be complete and it wants it now. It is the dryest of bone-dry legislation that it would have passed. One feels that in a week we have progressed a whole decade.

PROHIBITION WILL INCREASE NATIONAL WELFARE

This action will so ameliorate the condition of the working population that the workingmen will never cease praising the union for what it has done for them, just as they praise the union for the greater earnings that come from mechanical appliances, for the fatter pay envelope that comes from a depreciated currency and for the greater comforts that come from the inventor's ingenuity. All that ameliorates or even appears to ameliorate the wage earner's lot is credited to the work of the wage earners' tribunes, whether they oppose these ameliorating influences or support them.

But this we must concede: Frank Farrington, big-souled Frank, is out for prohibition. If the measure goes through the mine workers have a right to thank him. How he can come from Streator, Ill., and yet advocate prohibition, passes explanation, but we are told, nevertheless, that he does.

INDEPENDENCE DAY WAS THE ONLY WORKDAY LOST

Undoubtedly prohibition is the nation's best bet in peace or in war, and especially in war. It will add immensely to our production, and therefore to the booty which the people of the nation will yearly divide. Nevertheless one can hardly concede that this year's Independence Day celebrations were so harmful as has been represented. The nation only lost one day's coal. The figures of the United States Geological Survey show that in the other five week days more than an average production of coal was secured. The week's output of bituminous coal was 10,259,000 tons, or 2,052,000 tons per working day. There is little evidence that the drunkenness and abstention from work on July 5 exceeded that on a normal day. If it did, the coal output must have been made good by patriotic miners who tried to make up for the idleness of Independence Day.

James B. Neale, director of production of the United States Fuel Administration, visited northern West Virginia last week and made addresses to the mine workers at Monongah and to the coal operators assembled at the Fairmont Country Club. There was a little note of reprimand in his address to the operators. As we have said before, the operator is being asked for things, possible and impossible; the mine worker for something he can unquestionably provide, namely, 8 hours' work, 6 days a week. However, some of the things the operator thinks he cannot do can be done if he feels sufficiently distressed about the matter to be willing to do the necessary scheming and contriving. Some operators are not any too observant as to the difficulties that confront the mine worker and are a little too close in providing supervision, adequate repair force and adequate supplies.

Attempts are still being made to show that the anthracite operators are trying to reduce the number of their employees. We are told for instance that 11 employees engaged in the construction of a new breaker at Woodward colliery, of the Delaware, Lackawanna and Western Railroad Co., at Edwardsville, were laid off on July 11. With the suspension of these 11 men, we are told, the number of idle men, presumably at Edwardsville, is increased to 103, for 92 were suspended by the company several weeks ago.

The men thus laid off had been asked to work Sunday so as to bring the work to a speedy conclusion. They consented, believing, it is said, that double time would be conceded them. On inquiry they found they were credited only with a day and a half. The men objected and with one of the firemen on the job went to Scranton where, following a conference with the superintendent, they were paid off and discharged.

These men were probably not mine workers. Their discharge, therefore, is not the discharge of a mine employee. If they were mine workers they were demanding something to which their contract did not entitle them. Their idleness would therefore condemn themselves and not the company.

The Central Pennsylvania Coal Producers' Association has been preparing a report on the number of miners, cutters, scrapers and loaders employed in May of this year as compared with the number working in March of last year. The purpose is to make the fact deduced the basis of an appeal for deferred classification of such mine workers as are subject to draft.

WASHWATER CAUSES A STRIKE IN PENNSYLVANIA

The Pittsburgh or western Pennsylvania district has had few, if any, strikes of late, but about July 8, 200 of the mine workers of the Arnold City No. 2 plant of the Pittsburgh Coal Co., located at Arnold City, Fayette County, went on strike to obtain an adequate water supply at the company houses. The company made an agreement last September with the Fayette City Water Co. to supply water, but whenever the water is low the water company shuts off the supply. State police were brought in to maintain order and eventually water barrels arrived. Washday needs being thus provided, the strike came to an end.

The troubles which, in the anthracite region, have doubtless justified the laying off of men are well illustrated at the Tuxhorn bituminous mine in Illinois. Men make it impossible for the employer to retain them. Sometimes they refuse to accept union wages or recognized union working conditions, and then as soon as they are idle they begin to bemoan the lack of patriotism of the men who for good and sufficient reason were compelled to put them out of their employ. In the Illinois instance the men quarreled violently among themselves, the foreigners refusing to allow the negroes dominance in the union. As a result the men refused to work. When at last they decided to get busy the company refused to admit those men to the mine who had been leaders in the near-riot that had occurred. The company will take the matter up with the union and if it is agreed that the men should be reinstated that will be done and the time lost by the men thus reinstated will be paid by the company. There are some men who are such trouble makers that a mine can produce more coal without them than it can with their so-called assistance.

The employees at the mine of the Railroad Mine Supply Co. at Kincaid, near Taylorville, Ill., walked out on July 1 and the mine has been idle ever since. The strikers declare that they walked out because 10 machinists were laid off when they demanded an increase in pay.

Strikes to compel better railroad service have not come entirely to an end in the state of Indiana though they are not as frequent as they used to be. One occurred recently and the details will be found interesting:

Three coal mines, on a branch of the Indianapolis and Vincennes R.R., producing approximately 3600 tons of coal a day, and employing 670 men, were made idle by a change in the schedule of a miner's train. Most of the men employed at these mines reside at Linton. The mines are a part of the Vandalia Coal Co.'s holdings. For a number of years the miners have gone to and from their work at certain hours traveling on the Indianapolis and Vincennes R.R. A few miners who live at Dugger, however, petitioned the railroad for a car to be placed on the switch in the morning and brought back in the evening. After this petition was granted it was necessary to start the miners' train from Linton 15 min. earlier in the morning and to schedule the train to arrive 15 min. later at night. The Linton miners objected to the change and refuse to work until the old schedule is restored.

The coal production of Alabama is steadily increasing, a pleasing outcome of the many appeals recently made to the miners of that state. Men who have been in the trenches, men who are now working for the Government in shipbuilding plants and in other war industries, have visited the Birmingham district and the mining sections of Alabama in large number during the last 15 days. They have addressed the workers and urged them to give the Government the benefit of their full labor, stressing the fact that fuel is one of the most essential elements in the present war crisis. Coal, coke and iron men state that while the mine production is not yet as great as is attainable there is much improvement in the output. The past week saw a larger production of coal than the previous week and the belief is general in the Birmingham district that the mine workers will from henceforth continue their efforts to keep the output at a maximum.

Much Impressed, Rust Men Work on Sundays

Even if the miners work six days a week and the full capacity of the mines is reached it is feared that the production will still be short of requirements. The demand for coal is the heaviest on record and it has been steadily increasing so that now the increase in the demands in the Birmingham district is practically double the increase in the rate of production.

George Gordon Crawford, president of the Tennessee Coal, Iron and Railroad Co., speaking during the week before a meeting of the mining interests of Alabama assembled to discuss coal production under war conditions, reported that this company broke all previous records for production at its mines on Monday and Tuesday of last week. According to Mr. Crawford, 14,000 tons of coal were produced on these days and that is 1500 tons a day above the average production.

The miners and other employees of the W. C. Rust Coal Co., operating the Sligo mines in Etowah County, are putting in seven days a week at the mines. Mr. Rust in reporting the increased production stated:

"Our miners upon learning the general need for coal voluntarily offered to work on Sundays if permitted to do so, hoping thereby to relieve, in a small way, the demand for increased fuel production. The offer was immediately accepted and our mines are now operating at capacity even on Sunday. We are in need of cars to transport the coal thus being mined."

Nation's Coal Men for Prohibition

The bituminous coal industry of the United States has during the war put itself squarely behind the prohibition movement. At least operators, representing 400,000,000 tons output annually, have so placed themselves recently, for the National Coal Association has memorialized the United States Fuel Administration to support measures for immediate nation-wide prohibition. This resolution was transmitted to President Wilson and published for public information July 12.

The operators in the Association are anxious for speedier action than is meditated in the Gore amendment. Why wait till there is an immediate coal famine to put in force the means to relieve it? We know we are going to be short of coal this winter. Let us not wait till winter comes and then at that late hour make belated and therefore inefficient provision against the shortage. All things considered, is not the summer when cars are plentiful the time to cut down drunkenness? When cars are scarce, as in winter, it really does not matter so much. Besides, in winter the stories of the shortage brace the miner; and in summer there is less to brace him, and liquor gets the best of his feeble will—reference being made alone, of course, to those who drink to a degree that interferes with their work.

Operators View the Saloon in a New Light

The mine operators have at times past been indulgent toward the liquor business, some feeling that a saloon brought men to their mining town and that prohibition would stop the flow of foreigners to America. It may be conceded that liquor does attract some men to the town where it is sold. But the operator would be better off without such men, especially in these days of division of labor, when one man's drunkenness muddles the whole mining game; for sober loaders wait on drunken cutters and sober cutters wait on drunken loaders, and both are waiting on drunken scrapers.

With national prohibition all mines will be on the same basis. The measure may conceivably prevent foreigners from coming to America, but surely only the intemperate kind. These we do not want after all. The foreigners we have seem to stay well in West Virginia without their liquor. That state does not regret the sobriety so far as it has gone. Instead it wants more. So the foreigner is not much repelled by prohibition, and if he were he can't leave now; nor can he just now be induced to come. It is more important, therefore, at least at the present juncture, to remove from him all that interferes with his work.

Let us quote at some length what the National Coal Association has to say, for it is grateful news after these years of dubious shifting on this momentous question:

"Regardless of political affiliations of the members of the association, and leaving out of consideration the moral issues involved, and basing its opinion entirely on economic and patriotic grounds, the committee unanimously and unqualifiedly believes that national prohibition for the period of the war is absolutely necessary to make effective this or any other plan for increased coal production. A comparison of the records of production of mines in wet and dry territories furnishes ample proof of the need of prohibition. The various instances cited to you today need not be repeated here, but they typify the experience of operators throughout the entire country."

"Our committee," said Chairman A. R. Hamilton, "is composed of practical operating men, representing all the principal producing districts of the country. They are men of all shades of personal opinion. Some come from wet states, some from dry states and some from states partly wet and partly dry. They all told their stories and presented their figures to show not only the relative efficiency of the mines as between wet and dry states, but the difficulties of working out any practical benefits from drink restriction along the border line between wet and dry territory. The result was a determined and unqualified stand for national prohibition.

"The committee feels that the drinking evil has become so rampant in the mining communities that its complete elimination is fundamentally necessary in the effort to speed up the mines sufficiently to get the 100,000,000 additional tons of coal this country will require this year. It is now up to Congress to make a clean-cut choice between booze for the mining communities and coal for the war and the public."

EDITORIALS

Housing in the Mining Regions

THE draft does not cause houses to be vacated, provided that business continues with pre-war activity. The families still remain, though the boys go to the front, and just as many houses are required to accommodate the percentage of working men who remain. The anthracite region has lost over 18 per cent. of its men since the war began. This represents the net loss. There has been a larger shift of labor than this loss represents. Let us suppose that only 75 per cent. of the force now at the mines represents what was there before the war or has been gathered from nearby homes. Then that 75 per cent. will require practically 100 per cent. of accommodation. The 7 per cent. must have found dwelling quarters for the most part in new houses or in houses previously vacated.

More men will be required to bring the force up to full quota, to make up for the inefficiency of the new men and to correct possibly the slackness of those who find they can secure the income they desire without steady work. To bring them in more and better houses must be built. The outcome will be satisfactory, and more perhaps than we can ever hope for, if the anthracite region can manage to get its full pre-war force by housing the men in dwellings 25 per cent. more numerous than sufficed before the war began.

For this reason the anthracite and bituminous regions alike can look forward to an era of building and improvement despite the high prices, the shortage of labor and the desire to keep expenditures strictly on a war basis. The coal companies moreover have now the money and inclination to make improvements wherever such work will secure and retain labor.

From the Schuylkill district of the anthracite region comes word that the Philadelphia & Reading Coal and Iron Co. at Beaverdale is placing electric lights, water and other conveniences in the houses occupied by its employees. New kitchens and porches have been added to the houses; the surroundings have been beautified. The rent is placed at $7 per month. The city dweller finds such a rate hard even to imagine much less secure. But even in the immediate locality prices like these are unusual. At Mount Carmel nearby houses no larger, better or more convenient are renting at from $12 to $15 per month.

Three other villages of the company are getting generous renovation. Concrete walks now being built make traveling easy, the windows of the dwellings are being enlarged, and electric lights and a water-supply in every house bring the village up to date. No longer do ten families "tote" their pails to a faucet or even a well on the street, as used to be customary in mining villages.

The anthracite companies, anxious to aid war gardens, are placing their land at the disposal of their tenantry and give one and all fertilizer from the colliery stables free; sometimes they even deliver it at the garden site. As a result of these actions and the need for houses, the tenant houses once idle are now occupied. Formerly out of repair and indifferently cared for, they are now homes of happy workingmen. Many new blocks of houses are in contemplation. The war, by accentuating the need for men, is almost sure to set new standards for housing. Neither tradition nor romance will ever nestle in a row of houses of the store-box type of architecture, and no one will ever make a home of any permanence where there is neither tradition nor romance.

Improvement in Illinois Mining

WHILE all interested parties to the proposition of greater recovery of coal in Illinois agree as to the necessity for further action, the steps which should be taken to secure it are not so evident. The chief obstacles now are the adoption of improved systems of mining and a modification of the contract between miners and operators, to enable a greater extraction to be made.

Much individual effort has been made to devise systems of mining which shall improve existing methods. Also state and Federal bureaus plan at an early date a more extended investigation of Illinois mine workings with reference to the cost of production and the percentage of extraction. The claim is made that mines are not opened up in the first place looking to big recovery of coal, and plans are now being formulated to leave larger pillars on the advance of the workings. Also, engineering skill is being sought more and more by operators to assist in planning underground work and to follow up the development along the lines laid out. Furthermore, mechanical appliances are coming rapidly to the front to enable more work to be done with fewer men. To secure greater extraction as well as safety, an entry-driving machine has been devised to permit of reaching the boundaries quickly and encourage a system of retreating rather than of advancing, as at present. Such a machine is now being tried out by one of the prominent coal companies in the southern part of the state.

But the leading suggestions and plans just noted are details. The proper channel for further extensive improvement is the Federal and state coöperative movement which has been working so effectively. The final solution seems to be a line-up of four factors: The state legislature, the mining bureaus, the miners' union and the operators. The freight carriers of the state are also vitally interested; the loss of coal may affect them even more than the operators. The latter can go to other fields and open up new mines, but the usefulness of a railroad may be destroyed in some cases with the exhaustion of coal in its territory. As illustrating the relative importance of coal mining and agriculture in Illinois, we only have to turn to reports for 1916 which note that about 30 per cent. of all freight

carried by the railroads of the state during that year was coal, while farm products are only half as large.

The present, however, would seem to be no time to experiment on new systems, unless they will fit in with existing methods. There is a general shortage of labor and a threatening scarcity of coal, and no interruptions to production would be tolerated. Today any change which would curtail output or cause unrest among miners would not be favorably received; on the other hand, during more normal times, the leading coal interests of Illinois would welcome suggestions which gave promise of relief from present conditions.

Low extraction has been laid at the doors of the mining men of the state, but judging from the numerous examples of fine modern plants throughout Illinois, the suggestion arises that the question of surface protection might be one if not the leading factor in the problem. If some one will explain how to handle the surface, the operators may do the rest.

American vs. British Ideals

AT A TIME when the British are our allies, it seems perhaps importune to call attention to the difference between the business ideals of our respective countries; but seeing that there is a tendency toward certain of these ideals in America, and a tendency toward American ideals in Great Britain, it is perhaps well to consider what they respectively are.

In Great Britain the individual seeks a place in a large commercial house, expecting to live and develop with it and rise slowly and steadily with the advance of the years. The house engaging a man does not take him on trial; it expects to keep him as long as he lives. The manager looks up his antecendents, inquires into his family, studies his record and finally makes the important decision whether to accept him or not. In fact, the selection may antedate by months or years the actual entering of the applicant into the "berth" thus filled.

Recommendations from the distant and interviews with the near precede the employment of a man in any business office. The employer is not hiring a helper, he is buying his services for a lifetime on progressive partial payments. The employee is buying a slowly ascending annuity and paying for it in partial payments of service.

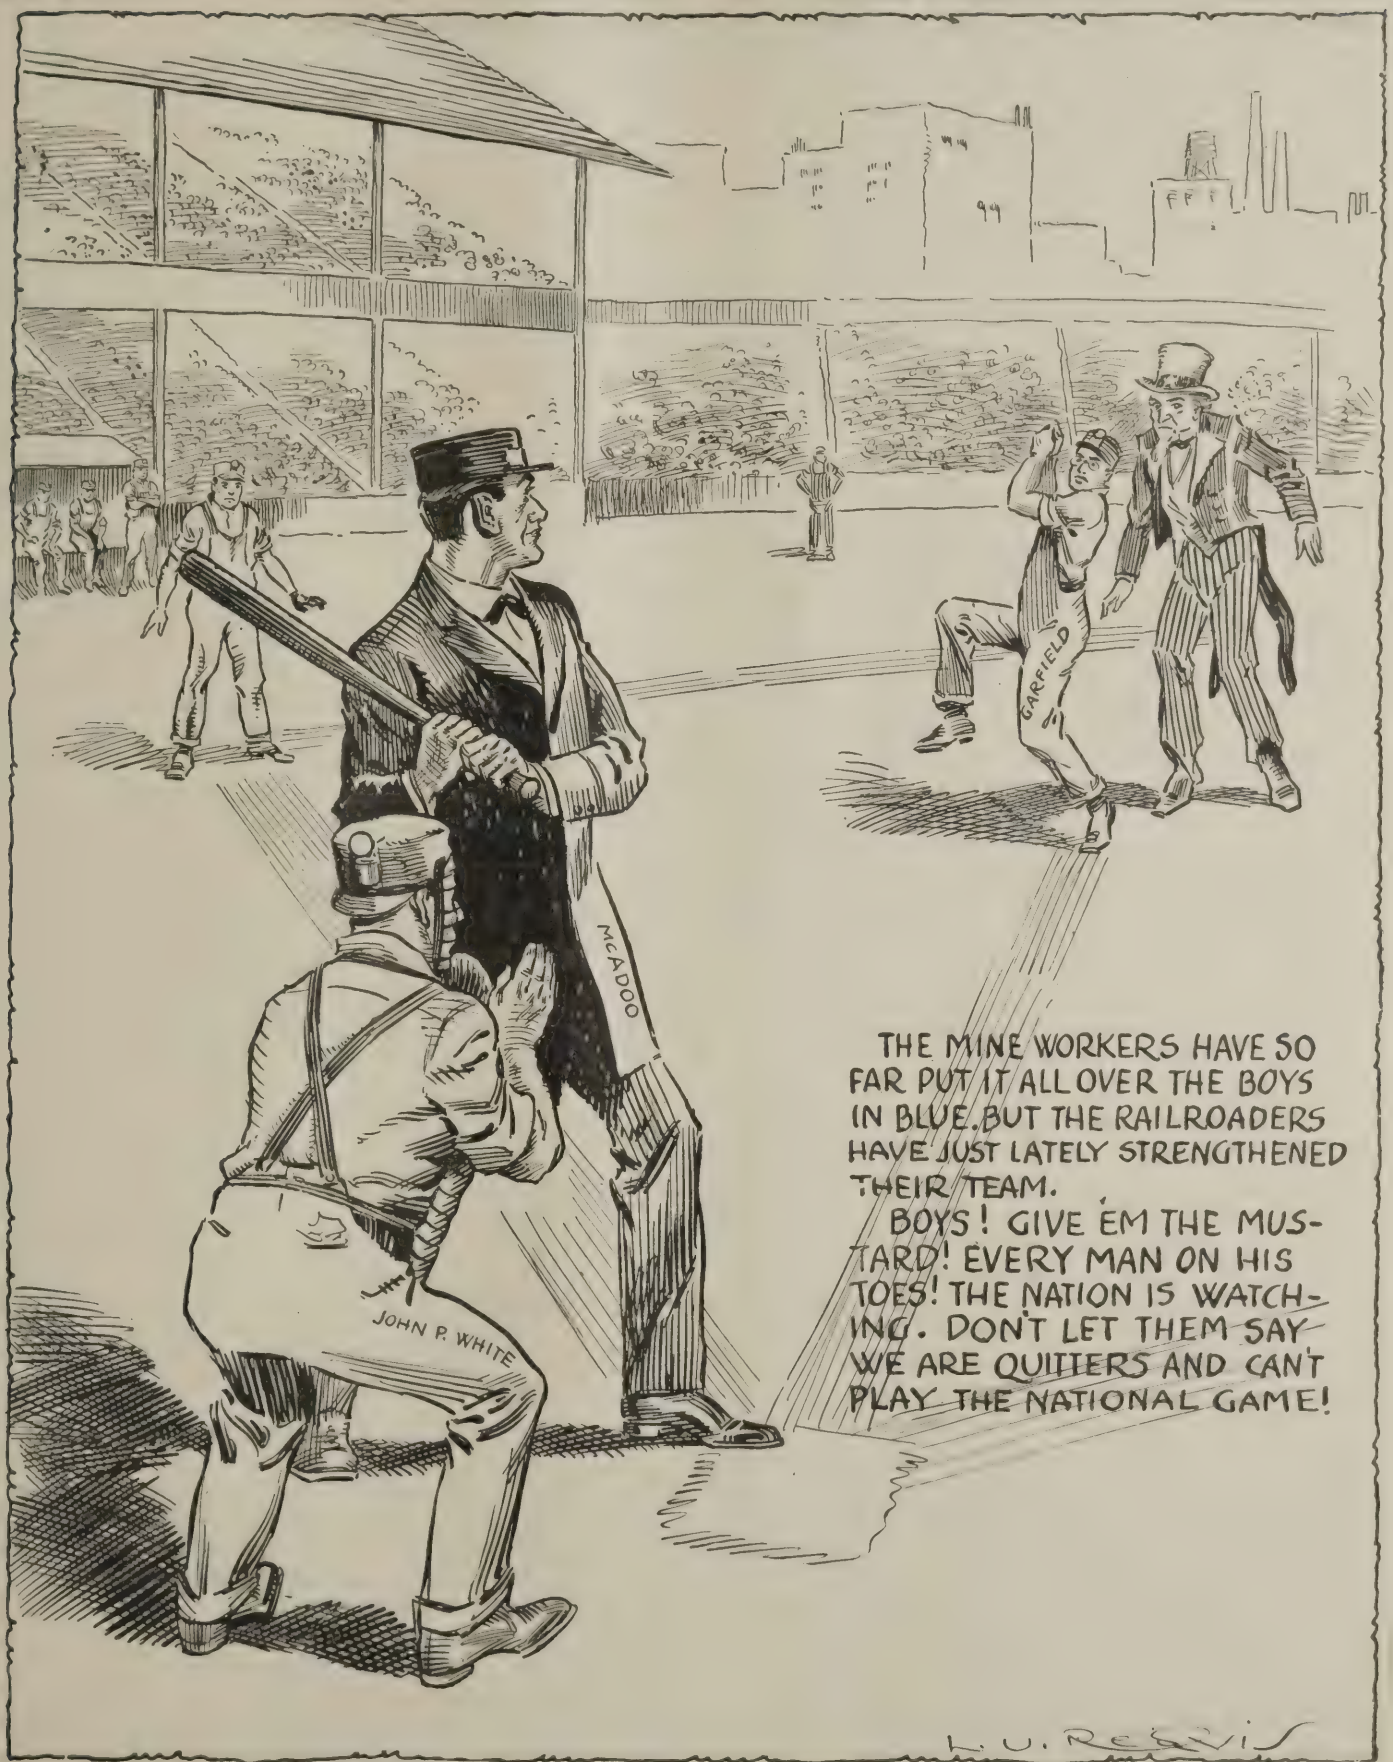
This used to be recognized so fully that it was unlawful to induce workers from one firm to accept service under another. But both employee and employer feel in large manner bound to one another. Theirs is no day-to-day contract. The law may say it is, but custom decrees otherwise; and customs are larger than law.

In Great Britain the employee goes forward in the company with the progress of his years and experience, whereas, with us, leadership does not merely come as a reward of seniority. Nor, it is true, does it solely so come in Great Britain. But in that country, nevertheless, as has been said, men enter a company in early youth and usually remain with it till they retire, climbing in it and with it, giving their lives in its promotion and development, regarding it as the end-all and be-all in their existence. The company feels morally bound to take care of these men. Only in cases of the grossest, most inexcusable negligence or malfeasance is a change made. To drop back in the line of progression is considered clear evidence of incompetence. Men do not shift from company to company. New blood is not sought; old blood is not rejected.

In fact, to express matters in American terms, Great Britain is a country where civil service rules dominate business as they occasionally dominate political service in America. The United States, almost without intending it, is drifting toward the British benign system of seniority and precedence, and away from the American system of the leadership of the fittest.

There are benefits in both systems. On the whole, we prefer the American plan. We believe it has vitalized our industries and that the contrary system has had a discouraging effect on British business. Men never leave a British company. They wait till the undertaker's horse removes those who precede them, and they step into the place thus left vacant—decently, of course, but none the less surely. They regard it as a wrong when a place thus left vacant is filled by any man outside the order of precedence, unless indeed he is related to a senior partner.

We have perhaps altogether too much turnover in our American executives. Too many corporation heads have a disposition to fill vacancies from outsiders they do not know rather than from insiders whom they do know.



An outstanding quality of a stranger may dazzle a chief executive, so that he will overlook the possibility that many unknown frailties of judgment will detract from the value of the stranger's services. Similar frailties in a subordinate being well known to his employer will condemn that man to his chief and result in his being replaced by a man whose success in securing a job is based as much on what is not known about him as on the qualities he is known to possess.

But with it all there is an advantage in leaving unobstructed the freedom of choice. The rejected always have hope. Some one in control may ultimately be won by certain of the employee's better characteristics and be not too well informed as to the others. Or again, another man may place the qualifications of his subordinates in a different order, and another job may be better tackled by a man of the subordinate's particular qualifications. So there is always hope, and where the hope depends on merit and personal endeavor a struggle for success always seems worth while.

Too much turnover is as bad as not enough. The soil needs stirring every so often that new elements may be brought to help fructify the field. Moreover, elements from outside need to be brought in. If Great Britain were as ready to cashier her business men as she is her statesmen, she might find it would not have altogether a bad effect on the conduct of her business.

If she did not hold in peace times such a beneficent opposition to discharge, the output per man might be increased and the welfare of her populace consequently augmented. The British workman is a competent artisan, but knowing his job is assured him he is a little too much inclined to "lay back in the shafts." The British executive is a well-posted official, but as his "berth" is secure he is a little disposed to "vegetate" and let himself drift in a sea of tradition.

Don't Let Them Take the Pennant

DISCUSSION BY READERS

Mining Equipment

Letter No. 6—Recently, one or two writers, in *Coal Age,* discussing the need of employing the most improved and up-to-date mining equipment, drew attention to the disinclination of coal operators to advertise improvements in their methods and devices used, or to explain the benefits derived from the installation of new types of machinery. It was urged, then, that the coal industry would be greatly benefited by a broader spirit of coöperation that would enable others to profit by our experiences.

Much as I dislike, at this time, to use this reference, it is an established fact that a great deal of the efficiency of German manufacturing methods was acquired because they had a large number of their brainiest men, whose sole duty it was to visit in foreign countries, going to as many of our up-to-date manufacturing plants as possible, where they had an opportunity to observe the latest and best practices employed.

It has been stated that when the war was first started, in 1914, there were nearly fifty of the leading mechanical men and engineers of Germany traveling incognito in the United States, and inspecting our manufacturing plants, raw-material supplies and methods of developing new articles. That they accomplished much for the German Empire goes without saying. It is further proved by the results of high-grade intercourse among the members of the industries having to do with the production of motor vehicles, farm tractors, agricultural machinery and a number of other lines.

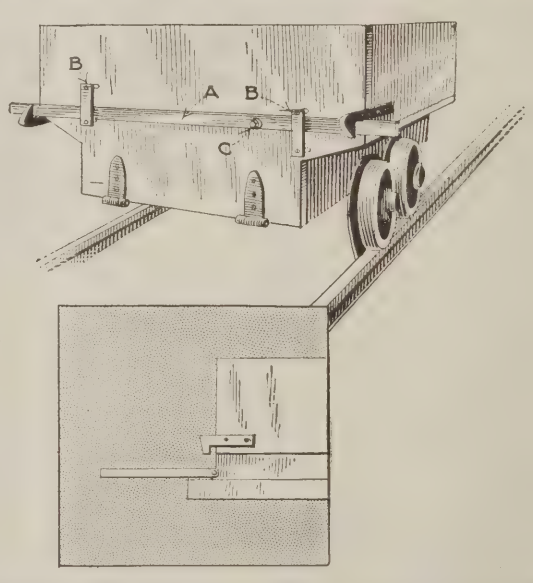
Broad-Minded Officials Needed

It is a fact, indeed, though I much regret to say it, that there has been a woeful lack of thorough coöperation and understanding between many of the coal-mining fraternity. This might be classed under the head of business policy or professional jealousy; or it may come from a lack of comprehension as to the advantages to be gained by the right kind of intercourse.

There are a number of companies, however, that are blessed with officials having a broader vision. When such are contemplating making new openings or enlarging their present plant they always make an extended trip through the various coal fields. I have a number of good men in mind who have covered the Illinois, Indiana, Kentucky, Ohio, Virginia, West Virginia and Pennsylvania coal regions, before making a move toward the new work.

A study of the recommendations of these men is convincing proof of the value of their action. It is to be regretted that so many of the higher officials of coal companies are not disposed to allow their operating officials sufficient expense money to permit of their visiting a few of the most up-to-date operations and observing the latest type of equipment in use.

The columns of *Coal Age* perform a powerful function, but the effect can be multiplied many times if proper heed is given to the suggestions and intelligent visiting is done by responsible operating officials.



Financial questions are often discussed by the moneyed powers, but with the exception of a few institute meetings, in the different states, and the meetings of the Coal Mining Institute of America, and the American Institute of Mining Engineers, no liberal interchange of ideas is offered to operating officials, who may be called the mechanical producers. They are the men who are definitely responsible for coal production.

I wish to advance the thought that a great deal of good can be accomplished by closer coöperation on the part of worth-while operating officials, and by a greater number of talks, face to face.

Philadelphia, Penn. PATRIOT.

Mine-Car Door

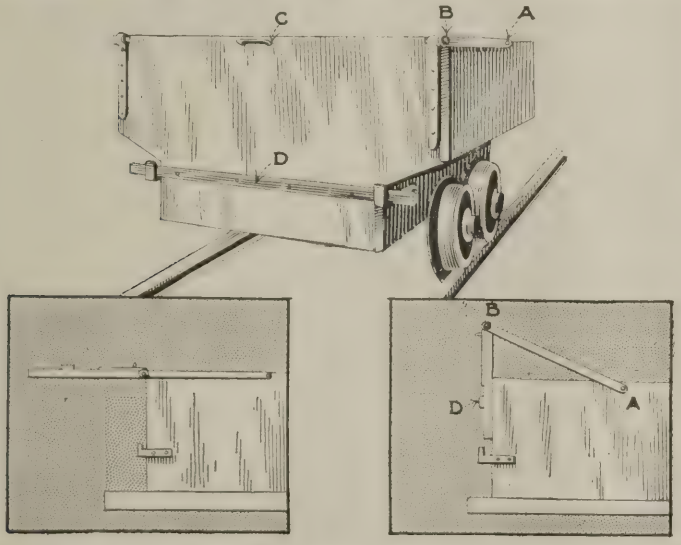
Letter No. 5—In response to the inquiry of V. C. Robbins, *Coal Age,* June 1, p. 1031, kindly allow me to submit the accompanying sketch of an arrangement I would suggest for hanging the end-gate of a mine car that will meet Mr. Robbins' requirements. He states

END-GATE HELD BY PIVOTED BAR AND LATCHES

that the gate must be hung so that coal can be loaded through the end of the car, instead of lifting it over the sides, as the seam is low. Also the gate must be so arranged that the car can be dumped automatically when hoisted on a self-dumping cage.

Referring to the figure, *A* is a dogbar made of heavy bar iron. The length of this bar must be such that its ends will extend from three to four inches beyond the sides of the car. As shown in the figure the bar passes under two heavy iron straps or brackets *B B,* which are long enough to allow the bar to play freely up and down

as required. The bar is pivoted on a heavy bolt *C*, which passes through the end-gate.



Bolted to the sides of the car are two "dogs" made of strap iron, each having a hook at the end to form latch fastenings for the bar. One of these latches is arranged for a downthrow and the other for an upthrow of the bar. The purpose of pivoting the "dogbar" on one side of the center is so that the downthrow end will be heavier than the upthrow end, which will cause the bar to fall readily into the latches.

The operation of this device is simple. As the car ascends on the cage, the downthrow end of the bar comes in contact with a projecting arm in the shaft and the gate is released, allowing the coal to fall from the car into the chute. Should the car, however, be on the opposite cage, the projecting arm on that side of the shaft must be hinged so that the rising car will pass it readily, but it will trip the dogbar as the cage is lowered for dumping into the chute. Each of these arms must be so arranged that they can be withdrawn if necessary, by moving a lever when the cage is ready to descend the shaft. For this purpose, a simple crank trip will be found most convenient. GEORGE W. RAMSEY.

Molus, Ky.

Letter No. 6—The inclosed rough sketch is submitted, in answer to the inquiry regarding the best arrangement for supporting the end-gate of a mine car, so that the car can be loaded through the end, in a low seam of coal, and still allow the gate to be operated automatically when hoisted on a self-dumping cage.

My plan is to support the end-gate on two long arms that are hinged about the center of the top of the car on each side, as indicated at *A*, in the accompanying

END-GATE HELD BY FIXED BAR AND LATCHES

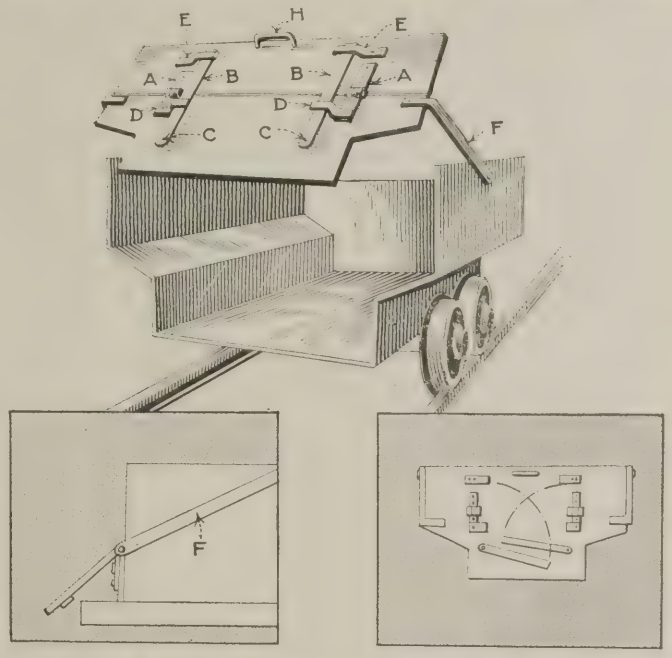


figure. This is the common form of supporting the end-gate of cars used on self-dumping cages. However, my suggestion, now, is to hinge the top of the door to the two ends of these bars at *B*. These hinges must be so arranged as not to permit the door to swing outward far enough to interfere with the grip of the door-lifter, at the top of the shaft, when it engages the hook fastened to the end-gate at *C*. In addition to these hinges, a straight iron bar *D* is bolted firmly to the end-gate, and extends beyond each side so as to drop into the side latches bolted to the body of the car.

No explanation is needed to show the operation, which is very simple. As the car is hoisted to the top of the shaft and the cage allowed to settle back, the hook *C* attached to the end-gate of the car is caught by the door-lifter hanging in the shaft. As the cage sinks to the line of the chute, the door is pulled upward and the coal slides into the chute. J. A. BIER.

Indiana, Penn.

Letter No. 7—I beg to submit the following suggestion in regard to arranging the end-gate of a mine car, so as to permit the coal to be loaded through the end of the car, in a low seam, and provide for the automatic dumping of the car when it is hoisted on a self-dumping cage.

As shown in the accompanying figure, the end-gate is made in two parts, hinged together by two stout hinges

DOUBLE END-GATE SUPPORTED BY SWING BARS

A A. When the car has been loaded these hinges are prevented from bending by two heavy swing bars *B B*, which are pivoted to the lower portion of the end-gate, at *C C*, and further strengthened by passing under two lugs *D D*. When swung into an upright position the bars are held firmly by two spring latches *E E*.

This arrangement will permit the dropping of the upper portion of the end-gate when the car is to be loaded in the mine. When the loading is nearly completed this portion of the end-gate is raised and the two bars swung into position and fastened by the spring latches *E E*, which can be made of any convenient form desired. The two parts of the end-gate now form one rigid whole.

As shown in the side elevation, the end-gate, as a whole, is supported by two long hinges of bar iron *F*, which are pivoted to the sides of the car near the top, about the center of the car. Attached to the top of the end gate is a strong hook *H*, which is engaged by the door-lifter at the top of the shaft when the car is about to be dumped into the chute. I believe no further explanation is needed to make the operation clear.

MATTHEW STAFFORD.

Coal Conveyors at the Face

Letter No. 1—Sometime ago an interesting article by Sydney F. Walker appeared in *Coal Age* (Vol. 10, pp. 744, 790), describing the benefits derived from the use of coal conveyors, at the working face. I believe this may be a fit subject for discussion, since there is at present a shortage of labor in all districts as well as an increase in wages, both of which conditions may be greatly helped by the use of face conveyors where they can be installed.

Experience teaches that the conveyor saves, in underground operation, in two ways. It increases the tonnage of coal that can be handled by one man, and decreases the cost of handling per ton. This is certainly something worth accomplishing. The result is apparently due to a couple of causes. The increase of tonnage handled by one man comes from decreasing the amount of time wasted. Formerly a man and his helper had to shovel coal along the face to the roadhead, fill the box, and tram it to the gathering place or the end of his road, and return with another box to repeat the process of loading. This was a great waste of time as compared with the conveyor system.

In the use of the conveyor, the means of taking away the coal is right at the man's back. He does not need to move from his place to load his coal, and the effort required is much less than when loading a box, owing to the small distance through which the coal must be raised. Another small advantage is that the percentage of round coal is generally greater in the conveyor, as the coal is turned over but once. This may be offset, however, in certain instances by the breakage occasioned at the roadhead where the coal is loaded into the cars.

How the Face Conveyor Reduces Cost

The saving in cost of handling appears to be attained through the reduction in labor; but I think this only applies to those coals that are, say under four feet in thickness, or to coals that require to have stone taken down for height in the roadheads. If we suppose a section to contain eight or ten roads, there must be a large sum expended in ripping down this rock to give the required headroom. Perhaps a foot or more of rock must be dropped and then built into packwalls, or disposed of in another way. The conveyor reduces this cost very considerably; but the extent to which that can be done is entirely dependent upon the seam, which brings us to consider the method of working.

Conveyors as we know them today are only adapted to long straight longwall faces. The type of combined conveyor and loader, designed to follow the coal-cutting machine from room to room, has not reached a practical stage of development, as yet. But the conveyor now in use makes it possible to work certain coals, under the machine-longwall system, successfully, that were failures under the hand-longwall system. The main reason for this is the speed of operation; or, in other words, the rapid advance of the face, which overcomes roof troubles that were apparently insurmountable obstacles in handwork.

The conveyor appears most likely to score its greatest success where the coal is relatively low and contains a band of stone that will provide good packs behind the face. Another type of coal that would probably produce equally good results is one where the roof breaks a little distance behind the face and completely fills the wastes, which can be assisted by a proper placing of the timbers. Under these two conditions the possible saving in operating expenses may be very great. Coals that are thicker and have roofs that won't stand the required span, but break short off, causing face falls of stone, lessen the saving, until the point is reached where it is necessary to employ another system.

I do not remember whether Mr. Walker explained that conveyors are not necessary adjuncts to coal cutters in longwall work; although they were, perhaps, first devised as a means of more quickly taking away machine-cut coal. Conveyors have been used successfully in mines where the coal is cut by hand. The use of a coal cutter and conveyor on the same face requires a good stretch of open roof, between the coal and the waste side. This cannot always be accomplished without too great a cost.

Where there is but room for one machine, either a cutter or a conveyor, the cutter will save on the cost of mining, which is generally considered the hardest part of a miner's work, while the conveyor saves on the loading. The ideal conditions are where both machines can be worked together.

Questions Affecting Installation of Conveyors

In conveyor practice, there are two points that require to be considered aside from the machine itself; namely, the manner of paying for the coal, and the attitude of labor toward the introduction of the machine. It is, of course, impossible to know how much coal each miner shovels into a conveyor; and the plan that has given the best satisfaction is to contract a conveyor face to one man. The plan of dividing the coal loaded from one face between the men loading on that face commonly gives rise to the usual squabbles and disputes.

The attitude of the miners is always a factor that cannot be ignored. Prejudice and lack of acquaintance with the system may be so strong that despite obvious advantages the introduction of a conveyor may be for the worse. It is best to introduce the subject slowly, talking it over at every opportunity with the men. Some miners will listen attentively to any new proposal and help it along, but there are others who regard such a move with suspicion.

In closing, let me say that the great field for conveyors is the thinner seams of coal, having a roof that will permit maintaining a considerable length of longwall face, in a straight line. There will generally be a greater output of coal for the same number of miners employed owing to the more rapid advance of the working face. This will require a greater number of mine cars and other equipment in proportion. It is important to remember, also, that a much larger quantity of coal will have to be handled on a single road, starting from the end of the conveyor where the coal is dumped into the cars. Unless ample provision is made to prevent congestion of loaded and empty cars on this road, the advantage to be derived from the installation of the conveyor will be lost through unavoidable delays.

Sydney, N. S. Mining Engineer.

Sealing Off Fire On Intake

Letter No. 3—From my experience with mine fires, I would say no two of them are ever alike. The character of the fire will depend on the material and amount of air with which it is fed. Sometimes these sources of feeding are very ample and there is produced such a violent sweep of flame in the entries that approach to the seat of the fire is most difficult and dangerous. At other times the presence of gas is the chief danger to be encountered.

In order to hermetically seal off a fire that has gotten sufficient headway to demand such a proceeding, I would attempt to build a 9-in. brick wall in each heading, outside from the fire and as close to it as practicable. I would build both stoppings at the same time and carry them to a height of 4 or 5 ft. At that point, I would cease work on the return stopping until the one on the intake has been completed, after which work on the return stopping should be rushed to completion.

In order to safeguard the men performing the work, I would make an opening in a stopping, a short distance back, sufficient to permit men to pass to and fro, as occasion might demand. This would also allow of the regulation of the air current, reducing the quantity of air passing over the fire but allowing sufficient air to reach the men performing the work of building the stoppings.

It is impossible to give an intelligent answer to the questions asked in regard to the condition of the air behind the stoppings when the stopping in the intake is closed first, or when closing the return first. The condition of the air behind these stoppings, in any case, will depend on too many variable elements, making an answer to these questions mere conjecture.

Allow me to suggest that greater safety might result from building the stoppings in a manner that will permit of their final closing simultaneously, by means of an iron door backed with asbestos. R. W. LIGHTBURN.

Perryopolis, Penn.

Letter No. 4—The question asked in *Coal Age*, June 22, p. 1173, is well worthy of discussion, especially in regard to the order of building the stoppings required to isolate a fire that has gained much headway.

On the first question, let me say that if I was in charge of a mine in which a fire occurred under the conditions mentioned in this inquiry, I would get together the necessary materials as quickly as possible and start and build my first stopping on the return entry, having previously opened a stopping outby from the fire, in order to short-circuit a portion of the air and not permit the entire current to reach the fire.

Having completed the stopping on the return airway, I would wait a short time, to allow the space behind this stopping to fill with the smoke and gases generated by the fire. I would then build the second stopping on the intake airway, as near to the seat of the fire as practicable. When building this stopping, I would carry a brattice along one rib of the entry, to conduct the air current forward to where the men are to work and allow it to return to the crosscut previously opened. This will give the men good air while performing the work. When this stopping has been built and closed, it will not be long before the extinctive gases produced will smother the fire.

Referring to the second question, permit me to say that should the intake stopping be built and closed first, the pure air lying between this stopping and the fire would shortly become charged with the gas generated in the heading and with carbon monoxide, which will be produced by the fire owing to the limited air supply, and an explosion is very apt to follow.

On the other hand, referring to the third question, it is clear that if the return stopping is built and closed first, the fresh air reaching the fire from the intake will probably prevent the formation of an explosive mixture.. Carbon dioxide will be produced by the fire, in this case, instead of carbon monoxide, and the space inside of the fire and behind the return stopping will soon be filled with extinctive gases, which should prevent an explosion taking place. THOMAS JONES.

Chickasaw, Penn.

Interpreting Mining Laws

Letter No. 7—Kindly allow me to refer to the question raised by Charles Martin, *Coal Age*, June 8, p. 1080, regarding what he assumes is vague in respect to ventilation, in the bituminous law of Pennsylvania. It seems to me that the meaning of the law is sufficiently explicit and clear regarding the ventilation of the working places in mines.

As has been pointed out in the reply to this inquiry, the law requires that each working place shall be ventilated in such a manner that it will be safe and healthy for work, which seems to be the determining factor. It would be impossible to comply with this provision of the law if men were compelled to work in an air current that had passed through a gob section in the mine before reaching the men, in the manner mentioned by Mr. Martin.

In regard to the distance apart for driving breakthroughs or crosscuts, the mining law in West Virginia provides that this shall not exceed 80 ft. unless brattice is used to conduct the air forward to the face of the entries. The law further provides that not more than sixty men shall be permitted to work on the same air current, except as permitted by the mine inspector under conditions that, in his judgment, make it impracticable to comply with this requirement of the law.

NO ECONOMY IN DRIVING FAR AHEAD OF THE AIR

Strictly speaking, it is neither economical nor advisable to drive entries more than 80 ft. ahead of the air, except for exploratory purposes, where brattice must be used to conduct the air forward. Unless the price for yardage is excessive, or conditions demand the driving of the entry a greater distance ahead of the air, it will generally be found more economical to drive the crosscuts within the limit specified in the law.

Referring to the question of what is to be understood by "return airway," let me say that I have always considered the return to start from the point where the air current passes through the last crosscut, on a pair of headings or in a particular section of the mine. Some complication may arise when a pair of crossentries have butt headings driven off them. The air from the return butt heading may then, in many

cases, pass into the intake crossentry and continue till it reaches the last crosscut on that entry, where it passes into the return entry. This is the case where the crossentries and the butts are both ventilated by a single current, which is often done in a nongaseous mine. In that case, the total number of men working on the crossentries and the butts must not exceed that specified in the law for a single air split.

In a nongaseous mine, however, the return from the butts should be conducted, by an overcast, directly into the return crossentry. This will provide a separate air split for ventilating the butts and the crossentries, respectively. In no case, however, should an air current that passes through a gob section be permitted to ventilate another live section, as mentioned.

Thomas, W. Va. W. H. NOONE.

The Mining Situation

Letter No. 4—Though I read with much interest Thomas Hogarth's letter, *Coal Age*, June 29, p. 1208, I cannot agree with him on all that he has said with regard to the present situation in coal mining. It must be admitted that the present mine-labor question is a serious one, and that something must be done and done quickly to prevent the scarcity of labor creating great loss in the anthracite field.

Much has been said recently in regard to miners not working full time, and some operators have asked their men to work more than eight hours a day. I want to say that if operators will give a miner all the cars he can load in eight hours, six days in the week, there will be no shortage of coal in the anthracite field the coming winter.

In my opinion, there are enough miners in this field to produce more anthracite than the nation can use. It is my belief that it is not the fault of the men nor the length of the working day, but miners are prevented from demonstrating their full ability to produce coal, because they are unable to get cars when they want them. At least, that has been my observation in this district. When a good miner receives but three cars a day and can produce coal that would fill seven cars he cannot be blamed for working short time and going home when he has loaded the cars given him.

SUGGESTS GIVING DRAFTED MEN SHORTER NOTICE

Where this condition exists, which is by no means exceptional, there is an evident loss of 50 per cent. in the capacity of the mine. Let me repeat what I have stated before, the remedy is not to be found in increasing the number of working hours per day, or in finding more miners for the work. There is, however, I admit, a shortage of drivers, runners and company men; but this can be offset, in many cases, by the adoption of improved mechanical equipment that will take the place of much man power.

It is true that time is lost by young men who are subject to draft quitting the mines, four, five, and six weeks before the time when they expect to leave for camp. The only remedy for this condition would be for the Government to revise their regulations in regard to notifying the men of the time they will be called. A shorter notice, say of a few days only, would cause little inconvenience and would hold the men in the mines to within a short time of their departure for camp.

Regarding the "National-Service Button" that a certain writer suggested should be given to men of draft age to indicate that they are engaged in work essential to the winning of the war, this appeals to me as being practical and necessary, particularly in coal mining. Like everything else, however, the scheme has its disadvantages. Unless properly safeguarded, it would do more harm than good, since there is a class of nonproducers who would drift into the mines, simply to avail themselves of the opportunity thus offered to escape the draft.

On the other hand, there are a large number of young men, who are efficient mine workers and who have no fear of the draft, but rather favor being given the opportunity to go across. I have heard many of this class say that "it is worth dying to see the other side, visit new places, and come in contact with new men." There would be no advantage, but great disadvantage, in replacing this class of good men with men who have no knowledge of mining and applying for work only to escape the draft. Coal is an absolute necessity and the output will fall short of the demand unless good miners can be held at their work in the mines. Let me say to every miner, You will show more patriotism by remaining steadily at your present work than by seeking to join the fighting forces "over there."

LURED BY OFFER OF HIGHER PAY IN OTHER INDUSTRIES

There is another feature affecting the coal situation, however, and it has the effect of drawing many good men away from the mines, when they find that they can make a dollar a day more at other work than mining coal. But, such men show that they love themselves more than they do their country, since they place their own interests before the Nation's needs. Patriotism demands that each man must work where he can do the most good.

In my opinion, the Government should take steps to prevent an employment agent from going into a mining camp or district and offering these inducements to miners working in the mines. It is true, as Mr Hogarth states, that the miner is receiving good wages today; but the price of living has advanced 100 per cent. and some necessities have been advanced 200 per cent. since the war began. Taking these things into consideration, the miner is earning less today than he was two years ago.

It is my belief, also, that Mr. Hogarth has overestimated the number of automobiles owned and run by miners. Such is not the case in the Wyoming valley, where it would be hard to find ten autos that are owned by the many thousands of mine workers in this region. I must also take exception to his statement that 90 per cent. of our miners being foreign-born "many of them cannot read and all they know is what they hear." Let me say that some of the smartest miners in the anthracite region are foreign-born, and, I believe, 95 per cent. of our men working underground can read and write. That is my conviction after working with them for 25 years, in the mines in this region.

Kingston, Penn. FRED B. HICKS.

INQUIRIES OF GENERAL INTEREST

Diffusion of Gases

Kindly explain what takes place in the diffusion of gases and what is its cause. The law of diffusion states that the rate of diffusion varies inversely as the square root of the density of the gas; but that does not explain the cause or the action of the gas in diffusing. It is this action that I am mostly interested in at the present time and hope to have explained. STUDENT.

La Salle, Ill.

The molecules of all matter are assumed to be in a state of constant vibration. The amplitude of the vibration, or the length of the path through which the molecules vibrate, varies with the density of the gas, being longer for a gas of less density and shorter for a gas of greater density. For this reason, when two bodies of gases of different densities are in contact with each other the vibration of their molecules at the plane of contact is not supported; or, in other words, there is a lack of equilibrium in the vibratory motion of the molecules at the point where the gases are in contact with each other. The direct result of this lack of equilibrium is a gradual progression of the molecules of each gas into or among those of the other gas, thus causing the two bodies of gas to intermingle.

Now, it is evident that, since the molecules of the lighter gas vibrate through a greater distance than those of the heavier gas, a larger volume of the lighter gas will pass over into the heavier one, and a relatively lesser volume of the heavier gas will pass over into the lighter one. The ratio of these interchanging volumes will be greater as the difference between the densities of the two gases is greater. For example, the specific gravity of marsh gas (CH_4) referred to air being 0.559, its rate of diffusion $\frac{1}{\sqrt{0.559}} = 1.3375$. In like manner the specific gravity of carbon dioxide (CO_2) referred to air being 1.529, its rate of diffusion is $\frac{1}{\sqrt{1.529}} = 0.8087$. The specific gravity of carbon monoxide is 0.967 and its rate of diffusion is, therefore, $\frac{1}{\sqrt{0.967}} = 1.0169$.

From these examples of the rates of diffusion of different gases it should be evident that the greater the difference between the densities of two gases the greater, likewise, will be the difference between the volumes passing over in each case; and again, this greater difference in the interchanging volumes of the two gases creates more quickly a uniform density of the mixture, and produces a quicker saturation and equilibrium of the molecules, because the heavier gas is made lighter and the lighter gas heavier more rapidly than when the interchanging volumes of the gases are more nearly equal.

Diffusion ceases when saturation takes place, and this occurs only when the mixture has attained a uniform density throughout. The aggregate of the molecular vibrations in the mixed gases is such that there is a complete balance of the reacting forces, and there is no longer any tendency to progression of the molecules.

Squibs vs. Electric Fuse

For many years I have been using the ordinary miners' squib for blasting coal. There is a squib known as the "Red Spitter." I would like to learn the opinion of *Coal Age* readers in regard to the question of which is the safest to use, the squib or the electric fuse, when blasting coal with black powder or when using permissible powders. Kindly explain what is meant by the electric fuse and how its use is safer than that of the squib. MINER.

Johnstown, Penn.

We shall be glad to have readers of *Coal Age* give their opinions in regard to the relative safety of single- and double-tape fuse, squibs, electric fuse and electric detonators, for blasting coal, explaining the adaptation and use of each of these means for exploding a charge. In former years shots were quite generally fired with ordinary fuse, and black powder was almost universally used in blasting coal.

Accidents were frequent in the performance of this work, owing to various causes, such as inferior quality of fuse, lack of care in tamping the hole, or inefficient tamping. While time has brought many improvements both in the methods and the devices employed in blasting, the prejudice of miners long accustomed to the use of fuse and squibs has been the chief obstacle in the introduction of electric firing and the use of permissible explosives.

The frank discussion of these methods and appliances, by practical miners, will go far toward emphasizing the danger to be avoided by the use of the more improved means for blasting coal. We will leave this question, therefore, for those who have learned by practical experience where the greatest safety lies in blasting operation. We will suggest, only, that contributors shall not confuse electric fuses with electric detonators, these two types of exploders being radically different in construction and operation.

Electric fuses resemble, in outward appearance at least, electric detonators. Each of these exploders have a cap containing a composition that is readily fired by an electric spark that passes between the wire terminals when the current is generated in the circuit. In the fuse, however, the cap is of heavy paper and contains chemicals that burn as a match; while the detonating cap is of copper and contains a fulminate that is highly explosive, and its detonation causes the explosion of the cartridge or charge.

EXAMINATION QUESTIONS

Mine Foremen's Examination, Carbondale, Penn., Apr. 23, 1918

(Selected Questions)

Ques.—What is meant by the terms "rubbing surface" and "friction," as used in mine ventilation?

Ans.—The term "rubbing surface," as the words imply, denotes the entire surface of the mine or airway, in contact with the air current. This includes the total surface of the top, bottom and sides of the airway.

"Friction" is the resistance developed by the movement of one body upon another with which it is in contact. In mine ventilation, the term refers to the resistance that the rubbing surface of a mine or airway offers to the passage of an air current.

Ques.—What is the minimum quantity of air required by law, for each person employed in the mine?

Ans.—The Anthracite Mine Law of Pennsylvania (Art. 10, Sec. 3) requires a minimum of 200 cu.ft. of air per minute, for each person employed in the mine.

Ques.—What advantage is obtained, in a mine, by having separate splits or districts?

Ans.—Dividing the mine into separate ventilation districts, each having its own air split, enables a better control of the ventilation. The quantity of air passing in each split can then be proportioned to the needs in the several districts. A larger volume of air can be circulated by the same power, and the velocity of the air current at the working face, in each district, is normal. At the same time, fresh air is supplied to each district, and the smoke and gases generated in one section of the mine do not pass through another section, but are conducted at once into the main return airway and pass out of the mine. Should an explosion of gas occur in one district, it is not apt to affect another district.

Ques.—What is the maximum quantity of gunpowder or any other explosive that a coal miner can have at any one time in his working place?

Ans.—Rule 26 (Art. 12) of the Anthracite Mine Law forbids a miner to keep more than 25 lb. of any explosive, unless more is required for his day's work.

Ques.—What is the purpose of safety holes and where should they be made?

Ans.—Rule 43 of the anthracite law requires that safety holes not more than 150 ft. apart and of proper dimensions shall be provided on all haulage roads used as travelingways, when the width of the road is not sufficient to permit persons to pass the cars with safety. These holes must be made on one side of the road only and kept free of all obstructions. Rule 49 requires safety holes to be made at the bottom of all slopes and shafts, in order to enable footmen to seek refuge in case of danger. Safety holes should also be provided wherever a door requires an attendant.

Ques.—How does the power producing ventilation vary as to the quantity produced?

Ans.—The power on the air, in mine ventilation, varies as the cube of the quantity of air circulated. Thus, to double the quantity of air passing in the same airway, will require $2^3 = 8$ times the original power on the air. This does not take into account, however, the change in the efficiency of the ventilator, which may require somewhat more than eight times the power applied to the fan shaft, in order to double the quantity of air passing in the mine.

Ques.—What would you suggest to reduce accidents with mine cars?

Ans.—Strict rules and regulations should be made and enforced regarding the movement of all cars and loaded and empty trips. No cars must be left standing in the mouths of rooms or on side tracks without being properly blocked to prevent their running out onto the main road. A suitable danger signal should be carried on the rear of every loaded and empty trip. Where two drivers are working on the same haul, they should follow each other and not alternate the trips. A reliable signal system should be maintained in use.

Competent trackmen should be employed to keep all roads in good condition, and every requirement of the mining law in respect to proper clearance at the side of haulage roads, refuge holes and other safety appliances should be strictly fulfilled. All cars and trips must be well spragged when descending a grade and a door should never be located at the foot of a grade. Close supervision must be maintained to see that the roads are kept clean and free from any obstruction. All rolling stock must be regularly and carefully inspected. The style of car used should be such that men are not liable to be caught when coupling them. There should be a safe limit to the speed of haulage and such other rules must be adopted as appear to be necessary to reduce the chance of accidents.

Ques.—How would you detect marsh gas (CH_4), blackdamp (CO_2) and whitedamp (CO)?

Ans.—The presence of marsh gas (CH_4), in the mine air, is detected by observing the formation of a cap on the flame of a safety lamp and the action of the flame, which is elongated and increased in size, depending on the proportion of gas present in the air.

Carbon dioxide (CO_2). is detected by the dimness and possible extinction of the lamp flame; also by the effect produced on the human system by this gas, which causes headache, nausea, pains in the back and limbs, when breathed for any length of time. Blackdamp is any varied mixture of carbon dioxide and nitrogen, caused by the depletion of the oxygen of the air, from any cause.

Carbon monoxide or whitedamp (CO) when present in the air is detected by observing its effect on small caged animals such as mice and birds. These little animals are quickly prostrated by the gas, the effect being much more rapid than is produced on the human system. The gas is extremely poisonous, the smallest percentages often proving fatal when breathed.

COAL AND COKE NEWS

Uniontown, Penn.

Trustees in bankruptcy of Josiah V. Thompson, former coal baron, have optioned 5000 acres of "back" coal in Whitely and Franklin townships, Greene County, for an average price of $350 per acre. Steps will shortly be taken looking toward the ultimate consummation by the courts of the gigantic deal. While it was announced that the options were given to Chicago interests, their identity was withheld.

The present deal was made immediately after the completion of the so-called Frick deal, whereby 1100 acres of Greene County coal was sold to the H. C. Frick Coke Co. for $3,700,000. It ranks second in importance to that deal, the total in the present sale approximating $2,000,000. While the consideration is almost $200 per acre less than that secured for the river-front coal, the price is considered equitable by the trustees because of its location. The Franklin and Whitely tracts are far removed from railroads and will be accessible only with difficulty.

For convenience in putting the sale through the court, many tracts were merged into one block to form the 5000-acre tract. Scores of coal landholders are associated with the trustees in bankruptcy in the $2,000,000 deal, and its consummation will dispose of the largest single block of Greene County coal ever transferred in one sale.

Manufacture of coke breeze has been placed under control by the local fuel administration in an interpretation of the new fixed coke-price order issued from Washington. In that order the price of breeze is fixed at one-half the established coke price, whereas in the past breeze from the local field commanded the price for prepared coke. Administrator Byers has ruled that coke breeze screened from the ash dump shall be classed as screen coke where it is free of impurities, but where careless loading is noted the product will be classed merely as breeze. That order creates a premium of $2 for clean breeze and a similar penalty for dirty loading. A rigid inspection will be made of cars loaded with breeze, Mr. Byers announced, to enforce the provisions of the order.

Charleston, W. Va.

The New River District has had no difficulty in securing an adequate supply of cars, and the power furnished has been entirely sufficient for the mines in the district since a vigorous protest was made to Washington. The car supply for the Fairmont district was most auspicious for the first part of last week, there being no less than 2116 cars in the district on Monday, 54 of which were coke cars. This supply was largely in excess of any received for some time, at least for the beginning of the week. The Monongahela road was able also to furnish the mines in Monongalia County a 100 per cent. supply, something extremely rare in that section. With 1792 cars in the Fairmont region Tuesday, a banner day in the district, not a mine was shut down.

Following a recent meeting of the members of the Winding Gulf Association, operators belonging to that association are taking steps to put into effect the suggestion that increased personal supervision would be conducive to increased efficiency in the mines. The great drawback in the Winding Gulf territory seems to be the bad condition of railroad tracks there. The car supply is ample so far as distribution is concerned, but delivery of loads and empties is interfered with because of frequent wrecks attributable to lack of proper maintenance.

Some idea of how production was affected in the Kanawha district by the Fourth of July lay-off may be obtained from the production figures for the district for the week ending July 6, only 147,729 tons being produced as against 195,000 for the previous week. A further idea of the exodus over the Fourth and its effect on the coal industry is shown in the fact that the loss of hours due to labor shortage was 1061 and the loss due to the holiday lay-off was 1200. The car supply was excellent last week and the week previous. Loads shipped out during the first week in July were 14,078 and empties received 12,300. It is understood here that coal operators and lumber operators found it necessary to go to Catlettsburg, Ky., the nearest "wet" point to this part of the state, to bring back their miners.

Fairmont, W. Va.

Operators from twelve and one-half counties in the northern part of West Virginia, belonging to four existing coal associations, met at Fairmont last Friday and in one of the largest assemblages of coal men ever held in Fairmont sanctioned the organization of what is to be called the Northern West Virginia Coal Operators Association, the purpose of such organization being to bring the coal men of the sections covered into a more compact organization, and in order to encourage concert of action in all matters touching the coal industry.

In accordance with the sense of the meeting, C. H. Jenkins, C. H. Tarleton, E. Drennen, D. Howard and S. D. Brady were selected as a committee on organization and were vested with authority to prepare a petition for a charter for the new association. The following districts in the Fairmont region were represented and for each of them a temporary Board of Directors was named, designated as follows:

Fairmont Subdistrict—A. B. Fleming, Jr., A. C. Beeson, J. A. Clark, Jr., G. E. Petticord, C. H. Jenkins. Clarksburg Subdistrict—A Lisle White, D. Howard, J. M. Hoar, C. J. Ryan, V. E. Goecke. Elkins Subdistrict—E. D. Baker, A. G. Wodell, W. J. Williams, A. R. Miller, R. B. Isener. Morgantown Subdistrict—S. D. Brady, C. W. Chapman. Kingwood and Grafton Subdistricts—Two directors to be named. The three directors at large selected were: J. M. Wolf, of Fairmont; J. A. Jenkins, of Clarksburg, and E. Drennen, of Elkins.

A feature of the meeting was the presence of J. D. A. Morrow, one of Dr. Garfield's lieutenants, A. W. Calloway, Director of Bituminous Distribution, and J. B. Neale, Director of Production.

In addition to the foregoing a number of well known railroad and coal men were present, among such being T. L. Lewis, Secretary of the New River Association.

Terre Haute, Ind.

Production of coal by Indiana mines reached a record figure for June, 2,546,452 tons being hoisted as compared to 2,403,263 for May. The June record was made in spite of a shorter month of one day, a pronounced car shortage and some labor difficulty. The car shortage for the month was 11.32 per cent. as against 12.32 per cent. in May. The additional tonnage possible with a full car supply was 416,735. That is to say, had the railroads furnished a full quota of cars, Indiana mines would have produced almost 3,000,000 tons, or at the rate of 36,000,000 tons a year. Supplies in the future, however, are not only dependent upon the rate of production, but also on the extent to which railroad coal is shipped out of the state. So far this year there have been considerable shipments of railroad fuel and screenings to Columbus, Dayton and Toledo, Ohio, and many other eastern points, and there is a possibility that these shipments may be augmented before the season for shipping eastern bituminous coal to the lake ports is ended.

Indiana mines on the Pennsylvania R.R. have suffered the worst from the car shortage, that road failing by 22.92 per cent. to provide an adequate supply of cars. On this system the car shortage has been enlarged by the shifting of cars to Eastern mines to care for lake shipments. Little relief is promised for this month.

Birmingham, Ala.

Of importance in the Birmingham mining district during the last week was the announcement that the recommendations that the Government take over the Warrior River transportation project had been accepted by Secretary McAdoo, and that in the near future facilities would be established which would afford magnificent opportunities for the handling of a large tonnage of coal.

Not less than 200,000 railroad cars will be released in one year if the coal used at Mobile, New Orleans, and other points in this immediate district is handled by way of Warrior River, and this will be a big item for the mining companies too far removed from the river to attempt to avail themselves of its facilities, as the cars released by the river mines will then be diverted to the former for their use.

The Jefferson County Board of Revenue instructed its engineers to start work Tuesday, July 16, to prepare for the construction of four miles of improved highway from the Cahaba coal field to Birmingham. The object desired in the construction of this road is to furnish facilities for the wagon miners of the Cahaba field to transport their coal to Birmingham via auto trucks. The county is merely asked to superintend the work and to furnish engineers, and the miners and civic association have agreed to supply the funds, approximately $20,000. The miners also proposed should the road be completed within the immediate future they would pay a royalty for its use in transporting coal to Birmingham. The county board has not only accepted this proposition, but at a meeting last Saturday it was decided to start the work immediately, the county engineers to direct the work and county convicts to be worked if necessary.

Victoria, B. C.

The problem of western Canada's coal supply for the winter of 1918-19 continues to engage the attention of the public bodies of the chief cities of Manitoba, Saskatchewan, Alberta and, to a slighter extent, of British Columbia. It also is constantly before the operators of these provinces and, generally, is being faced by the latter by concentration of effort toward the increasing of production.

Recently a civic committee of the City of Winnipeg, Manitoba, visited Calgary, Alberta, to go into the matter of the securing of Alberta coal for that large Middle West industrial center of Canada. The members of this organization did not achieve what they set out to do, according to report. They were not satisfied with the cost of the Alberta fuel in Manitoba, where from their statements it retails at between $11.50 and $12 a ton, and they went to Calgary to meet the operators and to ascertain the actual cost of production, in the hope of being able to obtain a clear explanation of what they consider an exorbitant and unwarranted price.

In discussing the information obtained one of the committee members said that it appeared that the coal prices on cars at the mine was $4.95; that the freight to Winnipeg was $4.15; and that approximately $2 had to be charged for administration and cartage. He, therefore, admitted his inability to locate any excessive profit to any individual or individuals in the course of the progress of the coal from the mine to the consumer.

On the whole the committee was dissatisfied with the treatment received, it being stated that the mine owners would not open their accounts to inspection and that they seemed to prefer not to send any coal to Winnipeg rather than to cut prices. The operators also are quoted as having asserted that no dividends were being paid and that, in some instances, money was being lost.

The chief difficulty appears to be as to freight rates and S. C. Oxton, deputy minister of public works for Manitoba, and J. A. McDonald, acting fuel administrator for the Province of Manitoba, were in Edmonton, the capital of Alberta, recently, interviewing the fuel administrators of that province, with a view to discussing the whole situation and endeavoring to devise some means of obtaining a reduction in the freight rates between Alberta and Manitoba.

As the situation stands the leading citizens of Winnipeg as well as other parts of Manitoba prefer the paying of $14 a ton for the anthracite coal of the United States to from $11.50 to $12 a ton for Alberta coal. They are of the opinion that the difference in quality in favor of the imported fuel is so marked that it more than com-

pensates for the difference in price. There is the further point, however, that this winter's developments may make it impossible to get the American coal and the chance of such a contingency, there is no doubt, is creating a feeling of uncertainty and a desire to do everything possible to arrange for a supply from the sister province.

PENNSYLVANIA

Bituminous

Uniontown—Decision to continue the shipment of its entire output of 32,000 tons of coal monthly to the byproduct plant at Youngstown, Ohio, was reached at the annual stockholders meeting here of the Brier Hill Coke Co. The board of directors chosen is composed of J. G. Butler, Jr., George F. Alderdice, W. H. Warren, Thomas McCaffrey, W. B. Phelan and John Allen. Officers elected were Thomas McCaffrey, president; W. H. Warren, vice president; W. B. Phelan, secretary, and N. B. Fulton, treasurer. The company has 470 beehive ovens at Brier Hill, near here, but they have been abandoned since last October, although the plant has been operating steadily at capacity.

Thornburg—The Pittsburg Coal Co. has under agreement of purchase 40 acres of coal about two miles from Thornburg, in Robinson township, at about $800 an acre, or $32,000. The coal is under the tract on which stands the Summit House, and belongs to the owner of that roadhouse.

Kittanning—On July 8 the Furnace Run mine tipple of the Allegheny River Mining Co. was destroyed by fire. The tipple was not only burned but the long retarding conveyor down the hillside was also a total loss. The Kittanning fire department was called and saved the power house and other adjoining buildings. The tipple was equipped with special preparing machinery which will require some time to replace. The loss is estimated at $30,000. The fire is thought to have been of incendiary origin as there was no fire whatever around the tipple over Sunday.

Washington—George H. Thiess recently purchased two tracts of coal lands in this vicinity from the Hemphills. The first tract contains 160.223 acres and is in Independence Township. The consideration was $16 022.30. The second tract, 142.599 acres, in Hopewell Township, was bought for $14,-259.90.

J. O. Scott, of Washington, has disposed of the Pittsburgh coal underlying a tract of 131.55 acres in Donegal Township to John A. Bell, a well known coal operator, of Carnegie. The consideration was $13,155.

The Pittsburgh coal underlying the farm of the late Joseph W. Brownlee in Cross Creek Township was sold recently to John Steel, of Greensburg, for $49,000. The farm contains 194 acres and 89 perches, which makes the average price $252 an acre. The Brownlee farm adjoins the farm of the Patterson heirs. The coal under the latter tract was purchased over a year ago by the Pittsburgh-Southwestern Coal Co. at nearly $300 an acre.

Anthracite

Wilkes-Barre—Officials of the Lehigh Valley Coal Co. are planning for a general revision of the colliery system, with the view of reducing the size of the divisions by creating new ones. The purpose is to enable the division superintendents to give closer supervision to their collieries, now that there is such a strong demand for increased production. Information is fairly reliable that the Lackawanna division will be split in two, with the present superintendent, George P. Gallagher, retained in charge of all collieries on the west side of the river. The newly created division on the east side of the Susquehanna will come under the superintendency of Sheldon R. Jones, former inside superintendent of the lower end of the Wyoming division. R. A. Jones, of West Pittston, will be made the division engineer of the newly created district.

Blakely—Thirteen men were burned in an explosion of gas in the Lackawanna colliery of the Delaware & Hudson Co. on July 10, when the floor of the chamber in which they were working caved and the gas from the vein below came in contact with the naked lights of the men. The explosion resulted.

Freeland—The officials of the Harleigh Brookwood Coal Co., which is the company name for the Madeira Hill Co., in Luzerne County, Pennsylvania, held a booster meeting in Hazleton this week. All the company executives in the anthracite field were present at the meeting and dinner. On Saturday morning a fire of unknown origin completely destroyed the Harleigh Brookwood breaker structure and adjoining buildings, causing a heavy loss. This will mean a loss of about 800 tons daily. It is too early to state what plans will be used to keep the output of this mine on the go. The G. B. Markle Co. has a large plant nearby.

Hazleton—Lehigh Valley Coal Co. officials from all the divisions in this part of the state recently held a dinner and production meeting at Hazleton. This was followed by the announcement that in order to further aid in getting out coal the operating management of the company's holdings would be concentrated into smaller divisions, each with its distinctive operating department, including superintendent and mining engineer. Another dinner was given later in the week by General Manager Chase to the higher officials of the company at his Glen Summit home.

WEST VIRGINIA

Williamson—With the organization of a $50,000 company, the incorporators of the Dempsey Coal Co. plan, as soon as the usual formalities can be complied with and machinery installed, to mine coal on an extensive scale at Armor in Mingo County. Those principally interested in the company are Thomas A. Shewey and James Brumfield, of Armor; Lewis Dempsey, of Inez, Ky.; Floyd Brewer, of Warfield, Ky., and J. C. Haley, of Roanoke, Va.

Welch—Former Senator W. W. Whyte, of Welch, W. Va., is one of the leading spirits in the formation of the Tacoma Collieries Co., which has been incorporated as a West Virginia corporation with a capital of $50,000, although the company's operation will be at Tacoma, Va. In addition to Senator Whyte the incorporators are J. Logan Hill, Joe Zeglin, Louis Setany and Frank A. Olasz, all of Welch.

Welch—Impetus has been given the coal industry in McDowell County by a number of new operations, the latest entry in that field being the Browns Creek Coal Co., which with a capital stock of $100,000 has been organized by J. R. Greenwalt and associates.

Charleston—The Gauley Mountain Coal Co., of which R. H. Morris is general manager, is building half a hundred new houses at its Gauley River plant.

Greendale—Approximately $15,000 will be expended in necessary additions and improvements by the Greendale Mining Co. at its plant here.

Greenberry—With a view to increasing its output, The Miller Coal Co. is driving new openings at its plant at this place.

Hartland—R. M. French & Co. have made such progress with the construction of a plant at Hartland on the Coal & Coke Ry. that the company will soon be able to begin producing coal.

Under the direction of W. S. Wood, general manager, the Middle Creek Coal Co. is developing its property near Hartland in the No. 5 block.

Philippi—The Ford Run Franklin Coal and Coke Corporation is among the new companies just formed with a capital stock of $1,000,000. Lee J. Sandridge and others organized the new company, which will develop coal property on an extensive scale near here.

Morgantown—An addition to other companies in the Monongalia field is the Little Falls Fuel Co., which has been organized with a capital of $100,000. This company was organized by J. A. Aronson and others.

Logan—Coal lands will be developed in Logan County by the Donald Coal Co., as soon as plans are matured by Fred Haslip and his associates, who organized the company, which has an authorized capital stock of $50,000.

Morgantown—Prof. A. C. Callen reports that the total enrollment of students in the short coal-mining course, at the University of West Virginia, Morgantown, at the present time is 21, which is by far the largest attendance in this class in the history of the school.

OHIO

Marion—A pile of coal containing more than 100,000 tons, which was stored by the Erie R.R., is on fire, and strenuous efforts have been made to extinguish it. The cause is supposed to be spontaneous combustion.

INDIANA

New Albany—A committee of miners from Knox County has filed a petition with the Public Service Commission, asking for a larger supply of cars and better distribution, claiming that the poor supply and distribution are resulting in their losing 21.5 per cent. of their working time. This condition appears to be true of most of the southern Indiana section.

Terre Haute—Samuel R. Artman, chairman of the Industrial Board of Indiana, following a conference with William E. Stewart, of Terre Haute, Ind., has announced the appointment of Mr. Stewart as state mine inspector, to succeed Michael Scollard, recently resigned. Mr. Stewart is now president of District 11, United Mine Workers of America. The salary of the position, which is under the industrial board, is $2000 a year.

KENTUCKY

Middlesboro—The Lunch (Ky.) mines of the United States Coal and Coke Co. recently set a record for eastern Kentucky, if not a state record, when 59 railroad hoppers, of 55 tons capacity each, were loaded out in a period of ten hours. The company has made numerous improvements and will shortly have a maximum capacity of 12,000 tons daily. Two thousand new houses have been erected for miners.

Barbourville—The mines of W. H. Boggs have been sold at public auction to Byron Campbell, of Rossland, who with Robert Ridnor will operate the property.

Hazard—The Storm King Coal Co., with offices and mines at Jeff, Ky., has been reorganized, the present officers being F. E. Hadley, president; H. H. Coupler, vice-president, and L. E. Yoder, secretary and treasurer. The company is putting in new equipment and improvements to increase the output from 500 tons to 750 tons daily, and is erecting 25 new miner's homes.

ILLINOIS

Freeburg—The Mulberry Hill mine here has been sold for $190,000 to Iowa parties connected with the St. Clair Coal and Mining Co., of St. Louis.

Edwardsville—E. C. Donk, vice president of the Donk Bros. Coal and Coke Co., of St. Louis, announces that the company will start work about Aug. 1 on a new mine one mile south of Edwardsville, intended to have a capacity of 5000 tons a day, which will be 2000 tons a day more than is produced by each of the four large mines now in operation in the southern part of Madison County. The company has acquired a large field south and east of Edwardsville. The contract for the shaft has been let. Mr. Donk estimated that about three months will be needed to sink the shaft to the vein which is to be mined.

Carlinville—Machinery and lumber have been ordered for the local coal mine that Carlinville business men are promoting, which is to be opened just south of the city. C. G. McIntosh, head of the company, announces that coal rights under the property of Anna Stoddard have been acquired.

Foreign News

Winnipeg, Man.—Controller Wallace and Aldermen Queen and Heaps, appointed a committee of investigation into the ability of the western coal fields to supply the demands of Winnipeg, report that in 1916, the total of the coal produced in Alberta was 2,172,801 tons, and in 1917, 2,125,000 tons, while according to Chief Inspector Sterling, fuel controller for Alberta, the production for 1918 is estimated at 3,225,000 tons. The committee is of opinion that this should be sufficient to meet these requirements of the three prairie provinces, provided there is continuous production at the mines; but production can only continue so long as orders are received from dealers and consumers, as there are no facilities at the mines for storing coal. The report, therefore, emphasizes the necessity of ordering coal at once by all able to do so. Regarding the labor situation, the committee found, generally speaking, an ample supply of men available for the time of the year, and believe that as soon as harvest is over the labor supply will be sufficient to meet requirements. As to the relative value of western and anthracite coal, the committee found it difficult to arrive at any conclusion. While it was admitted by all that the heating value of Alberta coal was not as great as anthracite, estimates as to the difference varied from 25 to 75 per cent.

Toronto, Ont.—Experimental work to determine the economic possibility of manufacturing peat briquettes as a substitute for coal, for which an appropriation of $100,000 was made by the Ontario Legislature, has been unavoidably postponed until next year. Two machines of a new design for the manufacturing of peat fuel were ordered by the Ontario Department of Mines early in the spring to be put in operation at the peat bog near Holland Landing. Owing to inability to secure the necessary material, the manufacturer has been unable to supply the machines, which cannot be delivered in time to enable operations to be begun this season. Some experiments on a small scale in the drying of peat with gas engines are in progress near Cochrane.

in northern Ontario, but no solution of the main problem as regards the commercial feasibility of furnishing a peat fuel to compete with coal will be possible for at least a year.

Personals

W. H. Moore, formerly safety inspector for the Canadian Western Fuel Co., has been appointed manager of the new Wakesiah mine, now being opened by the same company.

Thomas Taylor, formerly overman at the No. 5 mine, Comox colliery, operated by the Canadian Collieries (D), Ltd., has accepted a position as overman of the Morden mine, at South Wellington, B. C.

R. L. Douglass, sales manager of the Devoy & Kuhn Coal Co., of St. Louis, Mo., has recently been commissioned a captain in the army, quartered at St. Louis, to see that plants with contracts for the War Department get their quota of coal.

J. Jemson, overman of the South Side No. 1 mine, Nanaimo colliery, operated by the Canadian Western Fuel Co., has been appointed safety inspector to succeed W. H Moore in that position, and Robert Laird has been made overman to succeed Mr. Jemson.

Obituary

Henry Vogue, who made and lost a fortune in coal mining at Staunton and Edwardsville, Ill., died at a St. Louis sanitarium July 9, aged 82 years. He had been sick for two months, but had eaten a hearty meal just before he expired. One of the first mines at Staunton, a gin shaft, was put down by Vogue. He at first hoisted the coal by mule-power. He prospered, and in later years sank four shafts in the Staunton field. A quarter of a century ago he was one of the wealthiest men of the district. Then he opened the Henrietta mine at Edwardsville, which was not profitable, and he lost in it all that he had made in the others. This mine was recently reopened by the Beck-White Mining Company.

Industrial News

Rockport, Ky.—The Rockport Coal Co. has filed notice of an increase in its capital from $100,000 to $200,000, to provide for business extensions.

Knoxville, Tenn.—The Standard Jellico Mining Co. has recently filed notice of an increase in its capitalization from $25,000 to $50,000, to provide for expansion.

Elizabethtown, Ill.—A. B. Thomas offers to the lowest bidder a contract for sinking a shaft for the Hillside Mines Coal Co., in Hardin County, to the depth of 150 ft. from the surface.

New Orleans, La.—The local office of the Edison Storage Battery Supply Co. has been moved from 201 Baronne St. to larger and more commodious quarters in the Mason Blanche Building. D. B. Mugan is district sales manager.

Columbus, Ohio—An additional appropriation of $3300 has been made by the Columbus City Council for loading equipment for the Columbus municipal coal yard, bringing the total financing up to $15,800, in preparation for business during the fall and winter.

Winton, Wyo.—The work on the new mine of G. W. Harris, at Winton, Wyo., is progressing rapidly. Contract for the coal tipple has been placed with the Roberts & Schaefer Co., Chicago, which equipment will include a Marcus picking table screen.

Frankfort, Ky.—The Lenox Railway Co., of Frankfort, Ky., was recently incorporated by H. M. Collins and others, and plans to construct 15 miles of railroad in Owsley and Morgan Counties, tapping some rich coal and timber lands and connecting with main-line roads.

Pittsburgh, Penn.—The Pittsburgh Mining Machinery Co., First National Bank Building, has been appointed selling agent for Mancha storage-battery mine locomotives in the Pittsburgh district, covering the eastern Ohio coal fields, northern part of West Virginia, Maryland and bituminous fields of Pennsylvania.

Knoxville, Tenn.—The east Tennessee and southeastern Kentucky bituminous coal fields are steadily increasing production, according to E. R. Clayton, district fuel representative, who in a recent statement showed that during the first week in June 269,000 tons of coal were mined; 286,000 in the second week, and during the third week 300,000 tons.

Jefferson City, Mo.—Wallace Crossley, Missouri Coal Administrator, has issued an order that from now on coal delivered to consumers is to be dumped in streets and alleys where bins and cellars are not so accessible that they can be reached without delay. The purpose is to expedite delivery by avoiding delay to teams, trucks and men. The order applies to all the cities of the state.

New York, N. Y.—The Lehigh Valley Railroad Co. transported a record tonnage of anthracite during June, the total amounting to 1,352,820 tons, an increase of 5615 tons over last June. In the tonnage of domestic sizes carried during the present coal year, April 1 to June 30, the Lehigh Valley carried 2,646,491 tons, approximately 350,000 tons more than was carried by any other road.

New York, N. Y.—Reports of exports of coal from the port of New York during May, 1918, show 4444 tons of anthracite at a value of $30,158; 8117 tons of bituminous valued at $58,118, and 2153 tons of coke valued at $30,868. During May of last year there were exported from this port 16,714 tons of anthracite valued at $133,327, 995 tons of bituminous valued at $7147, and 1900 tons of coke valued at $38,063.

Birmingham, Ala.—The Sloss-Sheffield Steel and Iron Co., will construct 120 Semet-Solvay byproduct ovens in the Birmingham district, with commensurate facilities for taking care of the byproducts, according to an announcement of J. W. McQueen, president of the company, the plant to cost something like $5,000,000. It is stated that the Federal Government has contracted to take the byproducts for use in the manufacture of munitions.

Louisville, Ky.—In compliance with the orders of Fuel Administration, under which southeastern Kentucky is to supply 350,000 tons of coal for shipment into the Lake district, the Harlan district operators will get out 90,000 tons monthly, which will be shipped to the Ore and Coal Exchange at Toledo, Ohio, which will ship ore in and coal out. The Elkhorn district and the Blue Gem district will also make heavy shipments of byproducts coal to the Lake district.

Lexington, Ky.—A number of rumors are floating through eastern Kentucky to the effect that the Louisville & Nashville Railroad Co. has plans for enlarging its terminals at McRoberts and Ravenna, Ky., and that it will double-track its main line between these points in order to facilitate handling shipments of coal from the Elkhorn territory. It is claimed that the work will start this year. The rumors are plausible, as many new mines have gone into the district and the tonnage is very heavy.

Columbus, Ohio—The announcement was made last week that C. F. Mayer, who has been executive secretary of the Ohio Fuel Administration since its start about a year ago, has resigned to take up work in his former position, with the traffic department of the New York Central Lines. He will be succeeded soon by James G. Young, traffic manager of the Columbus Chamber of Commerce, who has also been secretary of the Franklin County Fuel Committee. Mr. Young will hold both positions for the time being.

Newark, N. J.—Plans have been approved for the erection of ten coal pockets with a total capacity of 5000 tons of coal, at Overbrook Hospital, Newark, N. J. They are to be of reinforced concrete and will cost $60,000. The pockets will be connecting receptacles built along the railroad siding at the hospital. A motor conveyor equipment will be installed to permit the rapid moving of coal from any pocket in the event of danger from spontaneous combustion. The system of pockets will be protected by automatic registers that will detect and expose any danger of combustion.

Columbus, Ohio—All of the property of the Sunday Creek Coal Co., which includes leases, land held in fee simple, mining machinery and equipment, will be offered for sale at auction at the Franklin County Court House, Columbus, July 27. The order was issued by Judge Dillon of the Court of Common Pleas. An appraisement of the assets shows a valuation of $2,500,000. John H. Winder has been receiver for several years. John S. Jones, of Columbus, recently completed the purchase of all of the bonds, and the sale is the last step in a complete reorganization.

Toledo, Ohio—A considerable tonnage of coal is flowing from Ohio and West Virginia mines to the Northwest via the lakes, as is shown by the records of loading at the Toledo docks of the Hocking Valley and Toledo & Ohio Central railroads. During the week ending July 13 the Hocking Valley docks loaded 160,000 tons as compared with 157,000 tons the previous week, making a total of 1,495,000 tons for the season. During the same week the Toledo & Ohio Central docks loaded 45,000 tons compared with 61,000 tons the previous week, making a total of 745,000 for the season.

New York, N. Y.—There has been installed in the American Museum of Natural History an exhibit of peat, for the purpose of calling to the attention of the public that what is probably the world's most accessible peat supply is located in the Borough of Queens, between Maspeth and Middle Village. This bog of peat covers an area of about 100 acres, and the peat bed is from 10 to 15 ft. thick. The exhibit includes samples of dried natural peat, dried compressed peat, peat briquettes composed of ground peat mixed with coal dust, and unmixed peat briquettes.

Lexington, Ky.—One of the most important actions taken at a meeting of the Hazard Coal Association held recently was the appointment of a committee consisting of one member from the operating force of each concern, in order to stimulate production. This committee, when named completely, will consist of about 30 men. The plan is to start an educational campaign among the men, showing that they are as important in the winning of the war as the troops in the trenches. Production in the Hazard field has fallen off because of lack of labor and the fact that many miners do not work full time.

St. Louis, Mo.—The St. Louis Fuel Committee, with the approval of Wallace Crossley, Missouri Fuel Administrator, has appointed inspectors to examine coal delivered to consumers with respect to cleanness and weight. Administrator Crossley says that everything possible will be done to secure clean coal and in cases where inspectors have doubts about the weight it will be reweighed. H. G. Martin, assistant superintendent of the Ranken Trade School, has been placed in charge of the investigation of industrial concerns, which are to be reclassified with respect to their importance and efficiency for purposes of fuel conservation.

Fairmont, W. Va.—Charles F. Ice, chief inspector for the twelve and a half counties comprising the Fairmont district, as laid down by the Fuel Administration, has announced four deputy inspectors, effective at once, as follows: C. F. Posten, formerly local inspector of the Elkhorn Coal Corporation, of Fleming, Ky., who will be located at Morgantown. F. F. Robey, formerly tipple foreman and inspector of the Consolidation Coal Co. mine No. 51 at Shinnston, who will be located at Shinnston. U. N. Arnette, formerly general superintendent of the Antler Coal Co. of Fairmont, who will be located at Elkins. C. W. Ferguson, formerly superintendent of the Copen Creek Coal Co. at Bower, W. Va., who will be located at Buckhannon.

St. Louis, Mo.—The Interstate Commerce Commission hearing on the petition of the St. Louis Chamber of Commerce for abolition of the bridge arbitrary of 20c. a ton on coal came to an end at the Jefferson Hotel on the afternoon of July 12. The hearing of testimony occupied three weeks. At the conclusion of the testimony the attorneys for the Terminal Railroad Association and the roads composing it renewed their motion for the dismissal of the petition, on the ground that since it was filed the freight rates have been changed by order of President Wilson, effective June 25, and that therefore the petition does not apply to the present situation. The motion is to be argued before the commission in Washington. It is the belief that a strong case has been made and that St. Louis will get relief from the arbitrary unless technical objections prevail.

Columbus, Ohio—The Ohio Industrial Commission, which has charge of the Ohio Mining Department, has issued a partial statement showing that the coal mined in the Buckeye State for the year 1917 was 41,677,986 tons. This compares favorably with all previous years and is in access of the largest previous production by 5,392,500 tons. The production in Ohio in 1916 was 34,526,552 tons and in 1913, which was the banner year previous to last year, it was 36,285,468 tons. Belmont County as usual is the leader, with 11,156,626 tons. Athens County comes next, with 6,313,619 tons, closely followed by Jefferson County with 5,742,240 tons. Guernsey County produced 4,024,265 tons and Perry County 2,445,114 tons. Hocking County is credited with 2,311,858 tons and Meigs County with 1,267,144 tons. Harrison County had a production of 1,222,561 tons, while Tuscarawas County produced 1,788,800 tons.

MARKET DEPARTMENT

Weekly Review

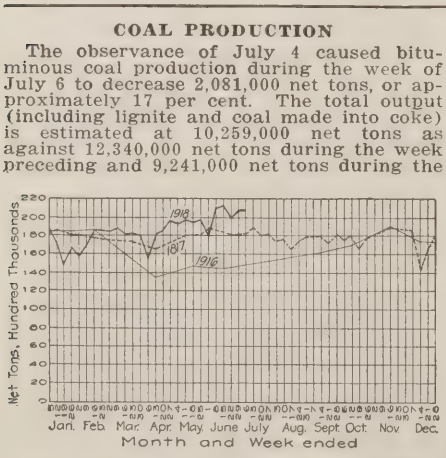
Prohibition in Mining Districts Would Mean More Coal—Bituminous Production Falls Off on Account of Holiday—Anthracite Situation Serious—Hard Coal Miners Placed in Deferred Draft Classification—Need for Conservation Emphasized.

THE enactment of a law providing for prohibition in coal-mining states would undoubtedly result in the production of more coal. There are many faithful and industrious mine workers, but there are also many who are not applying themselves with the requisite diligence to their important work in these critical times. Weddings, christenings, funerals, feast days, fast days—all furnish opportunities for the pleasure-seeking miner who desires to lay off from work. True, the war spirit has brought about a much better performance on the part of a majority of our miners, but there are still too many whose hearts and hands have failed to respond to the pleas made on behalf of patriotism, democracy, and the country's extreme need for more fuel. The lure of the saloon has resulted in a bending of the elbow—not in the interests of a greater production of fuel, but in the consumption of more liquor.

During the week ended July 6 (the latest statistics available), the production of bituminous coal amounted to 10,259,000 net tons, a considerable falling off in output as compared with the preceding week. This was due to the observance of Independence Day. Contrary to expectations, however, the average production per working day during the week under review maintained the high average of the week before. Naturally, anthracite shipments also fell off in the same week, only 31,493 cars being forwarded, a decrease of 25 per cent. compared with the week preceding.

Owing to the shortage of labor, the production of anthracite is falling below the tonnage counted on by the industry when a distribution program was worked out for the coal year. With added man power, the existing equipment and breaker capacity could get out at least 25 per cent. more coal. Through the loss of 33,000 men in the hard coal regions since the war started, the nation has been deprived of the potential energy sufficient to produce 19,800,000 gross tons of anthracite coal a year.

To prevent a further drain of the already sadly depleted forces in the hard coal regions, Provost Marshal-General Crowder has ruled that all miners and mine workers in these mines be placed in deferred classification in the draft. It is gratifying, indeed, that these workers are to be left undisturbed in this highly essential industry, as their services in the mines are vital to the successful prosecution of the fight against the Hun.



Following closely on the order curtailing the coal supply to brewers to 50 per cent. of their normal requirements, came the announcement that this industry is to receive no coal whatever. The incident which precipitated this order was a statement from the Railroad Administration that 200 additional carloads of coal could be handled through the New England gateways each day. New England's schedule is already far behind, but so closely has consumption followed after production that it was found necessary to divert supplies destined for non-war industries in order to fill the 200 additional cars each day.

While the coal available for use this winter will be intelligently distributed, and no recurrence of the confusion of last winter will take place, the requirements of the war industries are mounting so fast as to make it clear that there will not be enough coal for all. The Fuel Administration is indulging in no predictions as to what will happen to non-war industries, but every effort is being made to bring to the attention of the public the necessity of conserving fuel. Some are anticipating that 50 per cent. of the non-war industries will be forced to suspend before spring from lack of coal.

The work of supplying the domestic consumers with coal is going ahead more rapidly than had been anticipated, and there will be no inconvenience on the part of householders if they practice economy.

COAL PRODUCTION

The observance of July 4 caused bituminous coal production during the week of July 6 to decrease 2,081,000 net tons, or approximately 17 per cent. The total output (including lignite and coal made into coke) is estimated at 10,259,000 net tons as against 12,340,000 net tons during the week preceding and 9,241,000 net tons during the current week of 1917. The average production per working day (five-day week) is estimated at 2,052,000 net tons, slightly lower than the average production per working day during the week of June 29 of 2,057,000 net tons, and 11 per cent. greater than average production per working day during the week of July 6, 1917. Railroad shipments during the week decreased from all districts. Reports from the carriers show shipments from central Pennsylvania decreased 20 per cent.; from western Pennsylvania, 17 per cent.; from district including northeastern Kentucky, high-volatile of southwest Virginia and smokeless fields of West Virginia, 26 per cent.; from Ohio, 13 per cent.; from the district including Illinois, Indiana and western Kentucky, 20 per cent., and from the district including Indiana, Texas and the southwest states, 19 per cent.

Anthracite shipments during the week of July 6 decreased 10,148 carloads, or 25 per cent., the total movement amounting to 31,493 cars.

Beehive Coke—Production of beehive coke in the United States during the week ended July 6 is estimated at 579,000 net tons, a decrease compared with the week preceding of 25,000 net tons, or 4 per cent. The average production per working day is estimated at 97,000 net tons as against 101,000 net tons during the week ended June 29. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week ended July 6 at 348,178 net tons, their plants being operated at 76.7 per cent. of their present capacity as against 77.4 per cent. during the week previous. Slightly greater losses due to insufficient yard labor were reported during the week.

Byproduct Coke—Operating conditions in the byproduct industry changed but slightly during the week ended July 6. The plants were operated at 90.3 per cent. of their present capacity. Out of total losses of 9.7 per cent., 0.8 per cent. was due to shortage of byproduct coal, 2.2 per cent. to labor shortage, 5.2 per cent. to repairs to plants, 0.1 per cent. to "no market" and 1.4 per cent. to all other causes. Improvement was reported during the week from plants in Illinois, Massachusetts, New Jersey and West Virginia. The operators in Illinois and Massachusetts attribute the increased production to repaired plants, in New Jersey to better supply of coal and repaired plants and in West Virginia to repaired plants and other causes. Kentucky was the lone state reporting a decrease in production. The capacity of the plants reporting increased 8163 net tons during the week of July 6, due to the operation of a new plant in Ohio by the American Steel and Wire Co. at Cleveland and the operation of a new plant in Pennsylvania by the Carnegie Steel Co. at Clairton.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: June 15	June 22	June 29	July 6
Bituminous shipments, 123 roads.	222,892	212,849	219,625*	180,200†
Anthracite shipments, 9 roads...	41,960	41,170	41,641	31,493

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

American Wool and Cotton Reporter—Manufacturers are hoping to see lower quotations for wool, and there is some basis for expecting these lower prices. Wool has undoubtedly been accumulating, and if there is to be some trade development which will prevent other countries than the Allies from obtaining a reasonable supply when the war

terminates, the pressure of raw material stock might easily reduce quotations. The radical decline in the price of cotton on the official announcement of the cotton crop prospect was expected. While many thought the decline would continue gradually, the price nevertheless advanced nearly enough to counteract the previous decline.

Bradstreets'—While governmental control looms large in the general situation, and though movements on civilian account tend to narrow at the more important centers, zones close to the surplus crop growing regions report remarkable demand for this stage of the year. Buying of essentials is heavy, and though price-fixing on a lower scale has deterred operations in cotton goods, purchasers are more anxious to put out orders than sellers are to accept them, the newness of price regulations having rendered commission men chary about taking on heavy commitments.

Dry Goods Economist—The chief interest in the textile world shifted from wool to cotton when the announcement was made that the price-fixing committee of the War Industries Board had reached a decision as to what was a fair price of certain grades of cotton goods. The Board tackled only print cloths, sheetings and ducks, leaving other classes of goods for future consideration. In the case of the three classes of weaves "proper" prices were named for goods of standard counts and weights, in the gray—that is, the unbleached and unfinished fabric in the condition in which it left the loom.

Marshall Field & Co.—Wholesale distribution of dry goods for the week is substantially ahead of shipments for the corresponding period a year ago. Road sales for immediate delivery show a good increase over those of last year, while sales for future delivery are slightly under the figure for 1917. Customers have visited the market in about the same numbers as in the same week a year ago. Collections are normal.

Atlantic Seaboard

BOSTON

Volume all-rail gradually mounting toward quota, but deficiency since April 1 not being made up. "Budget" figures have not yet been reached. New England interested in prohibition talk. Railroad reserves creeping up slowly. Hampton Roads situation serious. Cargoes had to be found last week for twelve steamers waiting at the piers. Two hundred cars daily ordered to tidewater from western shipments in high volatile districts. Announcement that Pocahontas and New River contracts cannot be filled is believed soon to be forthcoming. Shipping begins to accumulate at loading ports. Occasionally necessary to divert steamers en route to Baltimore. Dr. Garfield's statement after visiting Hampton Roads causes comment. New England Fuel Administration enlarges organization to prepare for months ahead. Anthracite drops behind the June figures. All-rail movement fair, and demand keeps up for steam sizes.

Bituminous—To the first of the week the movement of bituminous all-rail had increased to such extent over the May average that the trade was much encouraged. As between different requirements, however, shipments are uneven and the situation calls for the closest kind of policing and supervision. "Jobbers," especially those of the mushroom character who have sprung up under "regulation," are having heavy consignments come through; but in cases where deliveries are in their own names without disclosing the ultimate consumer or distributor, the New England Fuel Administration is diverting the coal either to retailers or to industries who are on Preference List No. 1. A lot of this coal is started for "retail dealers" who never retailed before, and there are plenty of instances where the definition "physically handled" is being used in a way not to be recognized by those who framed it. Operators in considerable number are apparently shipping freely on orders of this kind and passing over the patrons they have had for years. Such cases are a hard test of one's faith in regulation, at least as now practiced.

The fact remains, however, that the volume of coal all-rail has much improved. Average daily receipts at the five gateways for the first 12 days in July were 616 cars of commercial bituminous. This is on a basis of approximately 4300 cars per week from central Pennsylvania, northwestern Pennsylvania, and the Westmoreland districts together. This is somewhat over the summer weekly quota for Central Pennsylvania alone, but is considerably short even for the "budget" the three districts are supposed to furnish all-rail

Washington has made a new program with regard to New England supply. Most of the changes are in the sources for railroad fuel, the latter being decreased from central Pennsylvania and increased from Westmoreland and from Fairmont. The result is a diminished burden upon the Altoona district for railroad supply, but it is doubtful if the volume of commercial coal for New England will be at all increased thereby. The great anxiety of operators over possible congestion at the New England gateways because of increased movement is not borne out by the actual situation. The New England roads are handling comfortably all that is delivered to them and the volume can be increased a lot more before cars will be delayed at the junction points or elsewhere.

The railroads are building up their reserve stocks only with great difficulty. Receipts of railway fuel all-rail still average considerably less than 150 cars daily from commercial consumers. After a fortnight of strenuous effort the Boston & Maine has increased its reserve only three days' supply, and it still stands at a point some 300,000 tons less than a year ago. The other railroads are only in less urgent position, and when the New Haven gets its storage depots in shape to take on coal a big movement will be needed in that direction. Cargoes as they arrive are being requisitioned more or less regularly for two of the railroads, and there is every prospect this practice will continue.

The most acute situation just now, however, is at Hampton Roads. Boats are arriving from day to day without coal being available. A week ago there were 49 steamers and barges aggregating 173,000 tons waiting at the piers, against a total available coal tonnage of 98,000. This week the number of vessels has increased to 60. Through strenuous representations to Washington Mr. Storrow was able to get coal for twelve steamers that were otherwise unprovided for. Three of these had to be intercepted on their way to Baltimore because congestion was also beginning to threaten at that point.

As an emergency measure 200 cars daily were ordered out of western shipments from the Kanawha and other high volatile sections along the Chesapeake & Ohio and again, late last week, a general embargo was put into effect on all west-bound coal. The increase in high volatile should clearly be made permanent, for this grade is in extremely short supply for all purposes. If the Westmoreland and other districts shipping to this territory all-rail are instructed to show preference in low sulphur coals for gas-producing requirements, it will be all the more necessary to build up the volume of coal from Kanawha and other high volatile districts accessible to Hampton Roads in order to relieve the needs of New England railroads.

Anthracite—For the first 12 days in June the average receipt of domestic sizes all-rail were 502 cars daily. This is a good showing, but it is not yet up to the June mark. Steam sizes are still coming through in good volume, the average for the mine period standing at 167 cars daily.

Retail dealers who have neglected making reports of receipts and stock on hand have been systematically notified, usually by telegraph, that their supplies will be shut off unless returns are made promptly. It should be said in defence of New England, in view of statements handed out to the press, that the number of delinquents is misleading. For instance, the Fuel Administration has names of 1200 "dealers" in Massachusetts alone who at one time or another have received anthracite in quantities from a carload up. Some of these were never in the retail coal business and others withdrew years ago. Yet they get telegrams from Washington! The list should be edited by someone in Massachusetts.

There are signs of slowing up on deliveries of steam sizes, but the demand is still strong. Plants of all kinds are accumulating buckwheats and nut in anticipation of shortage later on.

NEW YORK

Dumpings at the New York tidewater piers fall behind and the demand for coal continues. Discontinuance of shipments to three states may help local situation shortly. Demand for state fuel administrator keeps up. Labor shortage hinders bituminous production.

Anthracite—The smallness of stocks and the continued urgency for deliveries stand out as the prominent features of the situation. Dumpings at the New York tidewater docks were about the same as the previous week but local deliveries are far short of requirements. On the other hand most dealers admit having delivered more of their winter orders than they have under normal conditions. In some localities near New York dealers claim to be a month ahead of the season.

There is little difference in the amount of domestic sizes including Pea coal and Buckwheat No. 1 available. The latter is practically a domestic coal now.

Some shippers look for an improvement in supplies as a result of the orders issued by the anthracite committee of the United States Fuel Administration prohibiting shipments of the domestic sizes including Pea coal to 29 communities in Delaware, 72 communities in Maryland and 75 communities in Virginia. The committee has also issued a warning to producers and distributors who have already made shipments to a number of small towns and communities in excess of their whole 1918 obligation based on the 1916-1917 tonnage plus increased percentages. Suspension of such shipments is ordered and action must be taken to prevent a repetition.

The committee also says there are some instances where producers and distributors have actually shipped coal this year to communities into which they did not ship any at all during 1916-1917. This has also been ordered to stop, otherwise drastic action will be taken. Complaint has been received that insufficient tonnage is being furnished for domestic consumption to various towns and cities in New Jersey and Pennsylvania and the committee directs that regular shippers to these points arrange at once to forward the normal amount of tonnage plus the increased percentage.

The demand for a successor to Albert H. Wiggin, who resigned as state fuel administrator, is likely to bear fruit shortly, according to a letter received here a few days ago. The trade is fearful that the delay will cause a greater shortage here than would have resulted had the state been properly represented.

Consumers in Kings County who placed their orders early in April and who have not already received their coal will be compelled to pay for it at the price at the time of delivery, according to a decision of the local fuel administrator.

Shippers believe that the situation is going to be considerably better in the fall and winter, due to the heavy storing now going on in consumers' bins.

There is a heavy call for rice and barley with quotations for individual coal ranging from $3.10 to $3.25 at the mines and for individual barley ranging from $2.10 to $2.50 at the mines.

For the seven days ended July 15 there were 6870 cars of anthracite dumped at the local tidewater piers, a decrease of 81 cars from the number dumped the previous week. For the first half of July there have been dumped at the docks 14,025 cars of anthracite as compared with 14,648 cars dumped the first 15 days of June, a decrease of 623 cars.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Pea	$5.20	$5.95
Egg	6.35	7.10	Buck	5.10	5.90
Stove	6.60	7.35	Rice	4.65	5.10
Chestnut	6.70	7.45	Barley	4.15	4.30
			Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—Lack of labor continues to be the predominating feature in the situation, while the shortage of supplies continues to be such that as the season is rapidly passing building managers are becoming worried as to the prospects for next winter's fuel.

Conditions here show a slight change for the better. Some shippers report having been offered a few cargoes at alongside quotations, which were said to include the additional 35c. commission allowed jobbers. There was a decided scarcity of free coals, however. Regular customers, as a rule, received medium supplies and some are reported as having fairly good-sized stocks on hand.

The demand keeps heavy due to the expansion of war industries and the desires of manufacturers to prepare themselves for future consumption. Producers are ready to do their part in eliminating as much as possible the inevitable shortage which the country will face next winter, but there is a lack of labor which can hardly be overcome.

The demand that shipments to New England from this harbor shall be increased rather than diminished, notwithstanding the local demand is likely to continue since it is reported that the prospects of getting

more coal into the East from the Southern ports is less encouraging.

Production figures from the central Pennsylvania fields for the week ending June 29 show 1,142,420 tons of coal mined, the loss by reason of car shortage is estimated at 46,806 tons.

The dumpings at the local docks for the week ended July 15 were 6913 cars as compared with 7089 cars the previous week, a decrease of 176 cars. For the first 15 days of the month there were 14,202 cars of bituminous coal dumped here, as against 15,315 cars dumped during the first 15 days of June, a decrease of 1113 cars.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite shipments under quota. Dealers discouraged and believe relief far in distance. Domestic production decreasing. Retailers called on for more statistics. Producers taken to task for irregularities in shipping. Domestic buckwheat demand growing. Plants equipping for smaller steam sizes. Bituminous shows improvement. Good shipments arriving. Car supply good. Labor fair. Wagon-mine ruling not effective yet.

Anthracite—Shipments to this city have not improved, and there continues to be a slowly increasing pressure from the consumers for their coal. There is more coal stored away in the cellars of consumers than ever before, but when it is considered that last year established a record both in production and buying on the part of the public, and that there was a shortage during the winter, the seriousness of the present situation is realized. Production of fresh-mined domestic sizes is slowly dropping behind from month to month, and that explains the activity of the Fuel Administration in depriving manufacturing plants of buckwheat. The administration has limited the consumption area for anthracite and in addition has added two more counties of this state to the embargo list. This week a list was issued of about 25 counties in Virginia to which all shipments of anthracite are embargoed.

Retailers continue their efforts to get more coal, but without avail. Many of them seem resigned to the idea that heavier shipments will not be received for some weeks to come. In the meanwhile they continue to maintain their delivery organizations as fully as possible. One frequently hears of dealers who claim to be doing business at a loss on account of the lack of coal.

This week dealers were called upon for information concerning their business. They all received letters from the General Director of Distribution at Washington advising them that coal for domestic use is to receive preference in shipment and requesting weekly reports on a form provided by the Government. Information is desired as to the deliveries for domestic use, as well as to other dealers and to industrial plants. They must also show the number of tons on hand, their receipts and the coal en route.

The retail men are asked to report the aggregate annual tonnage handled by each, showing anthracite and bituminous separately; the aggregate amount in dollars of their 1917 business; the approximate aggregate amount invested by each in the coal business and the approximate number of men employed.

It is now quite a task to find a dealer who is willing to accept any additional business, and one large concern in the city, that had ceased taking orders several weeks ago, has unfilled orders for domestic coal alone amounting to over 100,000 tons.

Judging from a letter sent out this week to the various "producers and distributors" by the secretary of the anthracite committee of the United States Fuel Administration, all of them have not been governed entirely by the rules laid down by that body. Attention is called to the fact that up to the present time shipments in excess of the whole 1918 obligations, based on the 1916-17 tonnage, plus increased percentages, have already been made to a number of small towns and communities. Immediate action is ordered to suspend shipments to such points and to prevent it in any other direction. The letter states there are instances recorded where the producers and distributors have consigned coal this year to communities into which they did not ship any coal during 1916-17. They are advised that such practices must stop at once unless proper authority is received in advance. The committee threatens "drastic action" against delinquents.

Another matter likely to upset tonnage calculations is the fact that the army cantonments have not yet begun to take their full requirements of fuel. When these shipments begin in earnest there cannot be the least doubt, as last year, that everything will be put aside to take care of this tonnage, which is likely to be even heavier than last year.

There continues to be a moderately increasing growth of the domestic buckwheat trade. As indicated recently, the really foresighted dealers are taking all they can procure and this number is being occasionally added to. We recently learned of a dealer who never heretofore handled this coal but was surprised to find that two cars had been shipped to him. He raised no question whatever and dumped the coal.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—This week the soft coal trade has a more favorable aspect. Many of the mines, in fact most of them, report they have received practically as many empties as they can use. It is thought that this condition is partially due to the congestion of empties on account of the protracted Fourth of July holiday.

Good shipments have come into this territory recently and some plants have stocks much heavier than they have ever had at this time of the year. As a matter of fact the essential plants are in good condition as to the future, with coal piled high. These piles in many instances are thicker than they actually should be when the liability to spontaneous firing is considered. The heads of plants realize this and they are simply taking a chance, claiming that they have made preparations to handle such a situation should it arise.

While there has been much talk as to withdrawing all cars from wagon mines, yet this order does not seem to have been generally applied. A tour of the region this week discloses that many of these small operators continue to haul coal to the railroads for loading. There are also some murmurs of dissatisfaction as to this ruling, not only from the owners of the small operations but from the local consumers who are expected to purchase this coal. As the majority of these operations produce an inferior grade, the consumers tributary thereto do not feel that they should be compelled to take it, but want to be allowed to procure their supply as they have heretofore.

BALTIMORE

Increasing shortage is the cry from both ends of the coal trade here. Bituminous receipts continue light, and much poor coal keeps coming in. Anthracite men are genuinely worried, as each month shows a deficiency, and there is now a threat to cut the state's allotment.

Bituminous—There can no longer be a doubt but that soft coal distributors here, and this includes many of the Government fuel administrative force, are feeling genuine alarm over the fall and winter outlook. Instead of the shipments arriving during June and early July coming in such amount as to enable some stocking up for the winter, the tonnage has been scarcely able to meet urgent demands. Indeed, a number of industries have eaten into their scanty stocks in such fashion as to force an appeal to the state fuel administrator for some sort of preferential aid. This aid for the most part has consisted merely in sending the name to Mr. Brydon, the district representative, who now has a long list of requests beyond any apparent possibility of early shipment.

Not only are the receipts here light, but there continues a flow of bad coal that is discouraging. Following a complaint of ice manufacturers that they were frequently unable to get more than 60 per cent. efficiency out of the coal sent them, several other industrial groups have complained.

Even the cement makers, on a preferential shipment list, have not been without their troubles over poor grade coal recently. The 50c. per ton reduction in price plan of the Government to encourage clean coal does not so far seem to be working well.

A considerable tonnage is being received here for Government shipping account, and this movement has led some to confuse the general supply situation with it. Thus one Government official announced that the mines were not getting out tonnage because of poor rail movement, and another said that there was no trouble with the tonnage movement to this section, as it was up to normal. The real situation is that coal for ordinary industrial use is extremely scarce.

Anthracite—There can be no element of doubt about the anxiety of the anthracite handlers here. The receipts are far below the tonnage allotment announced for Maryland, despite the fact that a considerable amount of the shipments are also being diverted to war industries and other parts of the state than Baltimore. The spring and summer months have piled up such a deficiency that there is stronger talk of cutting down the two-thirds supply basis on orders until a betterment is in sight, in order that all may get at least a little coal.

The threat that is heard from the anthracite committee that the state's allotment may have to be cut is causing great anxiety, as the situation is bad enough as it is. A number of country clubs near Baltimore will be hit by the order that they cannot burn coal this winter. The wood fire seems to be the only solution, and for some of the clubs that will not be a happy one, as they are not equipped for adequate heating in that manner. Likewise a number of extensive private greenhouses are cut out from burning hard coal, and the plan to heat but half by bituminous will cause severe floral losses hereabouts. Wood-burning may come to the relief of some who can get wood without having it shipped by rail, which method will be banned as far as can be learned here.

Lake Markets

PITTSBURGH

No coal for stocking. Heavy extra demand for Lake shipments. Market narrow.

R. W. D. Gardiner, coal distributor for the Pittsburgh district, states positively that there must be no stocking of coal by manufacturing consumers or retail dealers prior to Oct. 15. This determination was reached as a result of the demand of the national Fuel Administration late last week that the Pittsburgh district increase its lake shipments as much as possible, over the 1,300,000 tons originally allotted for July, following 900,000 tons assigned for June. The Navy demands for smokeless coal will fall so heavily upon West Virginia and Kentucky that those districts may not be able to contribute any of their quotas to the Lake trade and a heavy burden accordingly falls upon the Pittsburgh district and Pittsburgh No. 8, in Ohio. The Pittsburgh district's production in July is expected to be 4,500,000 tons or a trifle over, and more than one-third of the output must go into the Lake trade if there are to be heavier Lake shipments than the 1,300,000 tons orginally set for the month.

Mr. Gardiner points out that the Lake coal shipping districts are in different position from other districts, in that the heaviest demands upon them occur in the summer, and stocking is therefore out of the question. If the plan succeeds, to have all Lake coal away from mine by Oct. 15, there will be a period in which large stocks can be accumulated, equivalent to the amount released. Meanwhile anyone who attempts to stock coal is likely to have his supply shut off and those who have stocks may be required to use them.

The local coal market has been narrow and is likely now to be much narrower. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, brokers being permitted to charge 15c. brokerage to consumers.

BUFFALO

Trying to get more anthracite locally. Movement by lake still light. Bituminous as hard to get as ever. Claims that the miners are idle.

Bituminous—The situation has not changed materially. Jobbers are making every possible effort to get more coal to handle, but with no further success. The mines are not favoring them, as is always the case when coal is in greater demand than supply. As this state of things is likely to continue indefinitely the outlook is not pleasing. Some of the jobbers report that their business is improving but as a rule they are still waiting for business to come their way. It is the idea of the trade in general that the Government does not think the wholesaler is needed in business.

The prices of bituminous, though supposed to be so rigidly regulated, are not as definite as they should be in the minds of shippers. They mostly have to figure considerably before making a quotation. Following are the latest figures: Thin vein Alleghany Valley, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; cannel, $6.15; smithing, $5.85, all per net ton, f.o.b. Buffalo, with jobber's profit added.

There is much figuring out of supply and needs of coal here by the fuel authorities, both in bituminous and anthracite, with the result, commonly, that some new consumer is listed as unnecessary and likely to be cut off soon. The breweries, for instance, are now down to half supply, but it is expected that in a few days they will be shut off entirely.

Anthracite—The local fuel authorities are looking for an allotment to this territory, after which an effort will be made to obtain more coal. As it is the city trestles are idle most of the time, sometimes not running more than two or three days a week. This does not mean that the midsummer movement is smaller than it used to be, but the demand is so urgent that if the coal could be obtained it would be brought in so as to stop the complaining.

The movement to Canada is light at present and the loading of lake vessels has not of late kept up with that of May and June. The demand for this coal seems to be too heavy in the direction of the war camps and for export to afford a full supply this way. The amount loaded for the week was 88,470 net tons, when an average of more than 100,000 tons has been the rule during the summer months.

The distribution was: 33,400 tons to Duluth and Superior, 17,570 tons to Chicago, 17,400 tons to Milwaukee, 8200 tons to Sheboygan, 5900 tons to Manitowoc and 5600 tons to Fort William.

Freight rates continue quiet at 60 to 65 cents to Chicago, 50 cents to Sheboygan, and Manitowoc, 55 cents to Milwaukee and 48 cents to Duluth and Fort William.

CLEVELAND

Car supply at southern Ohio mines has improved so greatly in the past week that shipments of bituminous are coming forward at a faster rate than at any time so far this season. The lake movement has been accelerated and, though many freighters are going up light, the Fuel Administration at Washington is expecting July to be a 5,000,000-ton month.

Bituminous—The middle of July sees bituminous shipments the best of the year to date. Car supply in the Pittsburgh seam district of southern Ohio, where Cleveland and northern Ohio get their supplies under the zone system, is reported to have been practically 100 per cent. on all lines in the past week. In fact, operators declare that at some mines there have been days when more cars were set than could be loaded. Inasmuch as shipments up the Great Lakes still are not all that could be desired, it is believed more coal than ever is going now into stock piles and cellars. Contracting continues at a low ebb; in fact, some operators say they have not made one for 90 days. Inquiry for harvesting coal—quite a factor in northern Ohio and Indiana with some No. 8 district operators at this time of the year—is coming in. More coal is to be seen on sidings and main lines between Cleveland and the mines than in over a year. The abolition of preferential car supply is working out excellently. Little has been heard here for the past two weeks of the "buy your coal early" movement. Latest statistics available at the office of the Pittsburgh Vein Operators' Association, for the week ended July 7, place shipments to the Great Lakes at 2105 cars; railroad fuel, 1151; Ohio, 1183; Michigan and Indiana, 138; and Canada, 54. These shipments were made as follows: Over Baltimore & Ohio, 2058; Pennsylvania lines, 1244; Wheeling & Lake Erie, 1228, and New York Central, 101.

Anthracite—Under the zoning system practically the only anthracite seen here is a few carloads a month, and no market for it exists here.

Lake Trade—One big shipper of bituminous up the Great Lakes who has just returned from Washington declares that the Fuel Administration is expecting July to break all records. Officials will be disappointed if shipments do not reach 5,000,000 tons, he declares, though July's quota is 4,500,000. The record month for the Great Lakes was September, 1917, when 4,900,000 tons of bituminous went forward. More coal cargoes have been available in the past week, but many freighters have gone up light. Iron ore is coming down at a record clip, and some cars that might be in the lake coal trade are engaged in expediting iron ore shipments off the docks to the furnaces. An extra effort is being made at present to get the Northwest's coal up as early as possible, since the ore season will be finished early in the Food Administration wants as many carriers as possible to go up light in the fall in order to speed the down movement of grain. It is figured that every lake cargo of grain releases so many freight cars that can be otherwise employed, and this indirectly will have its effect upon the coal industry. In the week ended July 6, which was a 5-day one, 747,535 tons of coal were dumped into freighters. In the week ended July 13, with the return for the final day estimated, the number of cars dumped totals 19,900 cars, which is better than 900,000 tons.

DETROIT

Neither steam nor domestic coal is reaching Detroit in satisfactory volume. No improvement in anthracite. Lake shipments are below schedule.

Bituminous—Complaint is still coming from jobbers and wholesalers that the movement of coal into the local market is much lighter than Detroit should be receiving to meet current requirements of consumers of steam and domestic stock, and provide adequately for reserves. While the supply reaching the city seems to provide fairly well for needs of industrial plants, little remains for storage. Most of the stock is mine-run. Slack and prepared sizes are received in much less quantity, and jobbers say there is considerable deficiency in supply of domestic bituminous.

State and county fuel administrators, and the dealers also, are striving to stimulate early buying by householders, in the effort to provide as far as possible for needs of next winter while transportation conditions are favorable; but the diminished volume of receipts is proving a troublesome handicap to the success of the campaign.

Anthracite—Uncertainty continues a prominent factor of the anthracite trade. Shipments are so small that retailers have made almost no progress in distribution. The gross margin allowable to dealers has been fixed at $2.50 a ton. Though the amount is unsatisfactory and is called inadequate, an appeal to the dealers on the ground of patriotic duty, which was made by James Couzens, chairman of the Wayne County fuel committee, influenced its acceptance. Regulations for distribution of anthracite were issued to the dealers by the state fuel administrator.

Household consumers using base burners are allowed their requirements up to six tons. Stove and chestnut sizes are to be reserved especially for users of base burners. Consumers having hot-air furnaces are to have one-half their normal supply of anthracite and are required to purchase one ton of bituminous for each ton of anthracite. Consumers operating steam or hot-water heating plants must provide themselves with fuel other than anthracite, as they are allowed none. This regulation has evoked a storm of protest. Violation of the regulations by dealer or consumer renders him liable to a fine of $5000 or two years in jail or both.

Lake Trade—Expectations of vesselmen and shippers are not being realized in lake shipments. Loading is short of schedule, which requires about 1,200,000 tons a week.

COLUMBUS

A good demand for all grades of coal characterizes the coal trade in central Ohio territory. Domestic buying is more active, and the lake movement is heavy.

The coal trade has developed a strong buying demand for all grades of coal—domestic, steam and lake. The lull in the domestic business is gradually passing, and retailers are now in the market for more tonnage. Steam and lake trade are both strong, and on the whole the tone of the industry is generally satisfactory. Production has been increasing under the influence of a better car supply.

Domestic demand is one of the strongest points in the market. Dealers are having a better run of business as consumers have been placing orders rapidly. Orders are both for immediate and deferred delivery. Retail stocks are low, as dealers have been unable to accumulate much surplus in the face of the heavy trade. The Franklin County Fuel Committee is supervising deliveries with a view of preventing hoarding in case such a thing should be attempted. Retail prices are firm at the higher levels announced several weeks ago. Still higher prices are in prospect when the new freight schedules are thoroughly worked out. Pocahontas is quite scarce in the local market. There is a considerable tonnage of West Virginia splint and New River arriving. The main fuel in the local market is Hocking, which is arriving in large quantities.

The steam trade is active also, as many of the smaller consumers are now in the market in an effort to get some surplus stock. This desire has not been gratified, as many difficulties are encountered. The demands for lake shipment are restricting steam tonnages in all sections. Schools have received the greater part of their fuel requirements. Public service concerns are looking around for a larger tonnage and state and public institutions are also in the market. The demand for threshing coal was extra heavy and taken care of by orders from the State Fuel Administration.

Production has been increased slightly because of a better car supply. This was especially noticeable in the Hocking Valley and Cambridge fields. Eastern Ohio still reports a car shortage, which coupled with labor shortage has been restricting production. In fact there is a growing labor shortage in every section of Ohio. This is due largely to the draft, which has taken hundreds of miners.

The lake trade is still active, and every effort is being made to rush a large tonnage to the head of the lakes. Reports show that there is a shortage from estimates made earlier in the season. The boat movement is active, as the ore trade is moving along without friction.

CINCINNATI

Market continues strong, with demand active and supply good. Car situation was not so good last week, but is expected to improve.

The steady demand for all varieties of fuel, from both industrial and domestic consumers, continues to take care of the large production being turned out and shipped from the mines in this section, and there is no surplus of supply over demand, making the situation ideal, as it has been for some time, from the standpoint of the trade. Domestic consumers, by placing in their basements practically their entire winter's supply of coal are making arrangements by which they will be better taken care of than ever before, and indications are that the entire current production of the fall and winter season, with the exception of the relatively small quantity required for emergency use by the poorer classes, will be available to meet the needs of the manufacturers and public utilities, who cannot possibly place in reserve storage enough coal to meet all of their requirements. Except in the New River district, where the Government's needs for the navy are being met, the car supply was not so good last week as usual, but this is expected to be remedied at once with increasing deliveries of new cars. Labor conditions are excellent at present, both as to the supply of men and their spirit; but operators are anticipating with gloom the effect of coming drafts upon their forces, inasmuch as the Government has not yet seen the necessity of exempting coal miners of all ages from military service. This measure has been urged as vital, and it is still hoped that it may be adopted.

LOUISVILLE

Demand for both steam and domestic running heavy, with dealers unable to supply domestic promptly. Production showing improvement in both fields. Car supply satisfactory, and considerable improvement in labor conditions.

The most important progress of several months has been made in the eastern Kentucky field during the past few days. It is reported that considerable labor which has been employed on farms, or working small holdings, has drifted back to the mines, resulting in a much better supply of labor and larger production. The car supply in June was much better than during any recent month, and there has been a good increase in production all around. The situation in western Kentucky has also shown some improvement, due to better car and labor supplies.

Kentucky and the Southern States dealers are becoming concerned over the future supply, as not enough coal is being received to take care of stocking orders, and no surplus stocks laid up. The situation is not very bright, and no improvement is in sight until the large shipments of coal now going to the Lake districts are completed and coal is again running to the small dealers.

The supply of eastern Kentucky coal reaching the Louisville market is now very light, and indications are that little of this grade will reach here until late in the year. Some Hazard coal, which is not a byproduct coal, is being received, and this with the western Kentucky grade is about the only coal that is being sold to any extent. Orders in a retail way are coming freely, and there is also a good demand for steam coal. No surplus stocks are in the yards, and it is now taking retailers ten days to three weeks to make deliveries on domestic stocking orders. On orders placed before the rate advance became effective the consumer is being forced to pay the increase, except where stipulations were made in advance.

BIRMINGHAM

Demand for domestic and steam coal shows no abatement. Supply and production about even with that of past weeks. Improvement in labor supply expected as result of coal mines being placed on priority list in the distribution of labor. Car shortage reported in a few instances.

Efforts of mine operators and fuel administration officials are now centered as never before on measures for increasing the production of coal in the Alabama field. The scarcity of labor and delay incident to delivery of material and equipment used in the industry are now the only serious factors crippling the production. A better labor supply is expected within the next week or two by the transfer of men from non-essential industries to the coal mines and other industries placed on the priority list for man power.

The requirements for steam coal are heavy, and much in excess of the supply under existing operating conditions. Railroads have fairly well provided for their fuel for the coming year, though of course the anticipated requirements have not been fully taken care of.

A steady and persistent buying movement is being maintained in domestic channels—both wholesale and retail—each month showing a substantial gain in the tonnage of storage coal. As one distributor expressed it, consumers are as much perturbed over securing their coal supply as if it had been announced that the domestic mines would close down about Sept. 1. Stocks in local yards are not accumulating, deliveries about offsetting receipts.

Coke

CONNELLSVILLE

Supplies practically adequate. Efforts to secure better labor performance. Narrow market.

Coke supplies at blast furnaces continue practically adequate but there is rarely any surplus to put into stock. Furnaces which had accumulated some stocks had no occasion to draw upon them after Independence Day, as production did not fall off at that time. Operators had made every effort to encourage men not to celebrate in the usual manner and their efforts were fairly successful. The campaign to educate the men to doing a full week's work every week, as a war service, has only begun and while hopes are entertained that this activity will be of some benefit it is the common opinion that absolute prohibition is the only really adequate remedy. It is maintained that even if prohibition should cause a considerable proportion of the men to leave the region there would still be an increase in the total amount of work done.

Good progress is being made in byproduct coke, plants recently put in partial operation having put on additional ovens while other plants are nearing completion. From May 1 to date the Geological Survey reports show an addition of 20,000 tons a week to rated capacity of the country, practically all of this being in Pennsylvania and Ohio.

The coke market is without incident. A fair volume of foundry coke is coming into the market, some of it being sold through brokers with a small commission paid by the operator. There are scarcely any offerings of furnace coke but furnace representatives are picking up odd lots occasionally. The market remains quotable at the set limits, $6 for furnace, $7 for foundry, 72-hour selected, and $7.30 for crushed, over 1-in., per net ton at ovens. Coke screenings from old dumps bring up to $6.50, but coke breeze has little sale, particularly as the byproduct operations offer a cleaner material.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended July 6 at 349,795 tons, a decrease of 2695 tons.

Buffalo—The demand for all grades of coke continues good and if the movement of iron ore by lake (325,507 gross tons for the week), continues the consumption of coke will have to increase. The plan is apparently to make a record, for the vessels are unloaded much more promptly than they sometimes are. Coke is hard to get and none worth mentioning is put on the general market, the furnaces buying of the ovens direct. There is complaint of lack of both cars and men, but the output is heavy. Fuel coke is in large demand, with amount to be obtained small.

Birmingham—Trade is quite active and there is a steady demand for much more than the available tonnage of either furnace or foundry coke. According to the statement of a prominent official of a foundry coke producing company, unless there is a natural increase in the output of this grade of coke in the near future industries in this district will be compelled to secure from 3000 to 4000 tons per month from foreign producers. The output has been reduced in the past few weeks by an increased tonnage of 48-hour coke for furnace consumption by one of the larger companies, and labor shortage and irregularity are contributing factors in further crippling the production. A new selling price has been announced by the Fuel Administrator for New Castle 72-hour selected foundry of $8.25 per net ton ovens. Other producers contemplate seeking an increase in price schedules as soon as data can be compiled from June cost sheets.

Middle Western

MILWAUKEE

Dealers swamped with orders for anthracite upon which no scale of prices has been fixed. Margin of profit for inland dealers is cut down.

Consumers of anthracite coal in Milwaukee are still in the dark as to what they will be called upon to pay when their bills for fuel are rendered. It is said this condition will remain until the Fuel Administration establishes the margin of profit from vessel to consumer, which is being determined by experts. Inland dealers have been allowed a maximum profit of $1.35 per ton on anthracite, $1.45 on household bituminous from lake sources and $1.70 upon soft coal from Illinois and Indiana. The latter margin also applies to coke. This is a decrease from $2.25 per ton, or the margin originally set by State Fuel Administrator Fitzgerald. An extra charge for delivery is subject to the approval of county administration heads.

Milwaukee coal dealers are swamped with orders. The leading dock company has closed its retail order department, as orders now on hand will keep its teams busy until the middle of December. The allotment of anthracite to small dealers has been cut down to such an extent that it will take far into the winter before they can supply their customers.

The labor situation is such that coal dealers are seeking the privilege of dumping coal in the streets at points of delivery, leaving the problem of putting it into bins to consumers. Coal dealers place the responsibility for delayed deliveries upon the fuel administration, because of its failure to fix a scale of prices.

Effort is being directed in Milwaukee and other points in the state to provide means for financing consumers who are unable to place their coal orders at the present time. A Beloit, Wis., manufacturing firm is assuming the coal bills of its employees and reimbursing itself in installments from the payroll.

By awarding contracts for 42,000 tons of bituminous coal for state institutions early in June, or before freight rates were advanced, the State Board of Control effected a saving of $7500 on 15,000 tons.

Cargo receipts by lake since last week's report aggregate 14,919 tons of hard and 161,050 tons of soft coal, making the total recepits of hard coal since the opening of navigation 172,591 tons, and of soft coal 1,094,357 tons.

The Milwaukee-Western Fuel Co.'s Sixteenth Street dock, on the Menomonee River, which has been in course of enlargement and reëquipment for a year past, is now being stocked with coal.

ST. LOUIS

Market shows growing strength on Standard, contrary to expectations. Carterville scarce, and other grades likewise. Car shortage develops seriously on some lines and transportation lags. Railroads begin to confiscate coal.

Contrary to all expectations, the local Standard market has taken an upward turn. While there is still an overproduction of coal in the Standard field to some extent, the market is stronger and prices are better. The steam sizes also seem to be improving. This is perhaps the result of more activity in railroad buying in the Standard filed. In a general way local conditions show improvement. The domestic trade is still dragging now as far as new orders are concerned, but there is the usual demand that cannot be taken care of for Carterville coal.

The high class trade in the city that has in the past been using anthracite and smokeless coals has not as yet begun to place its orders, with few exceptions.

Car supply in the Standard field is not all that it could be, but transportation shows considerable improvement in the last week, and this may account for better car supply in the next ten days to two weeks.

With a heavier tonnage of Standard for the railroads the market is going to improve, and this will have a tendency to better conditions by reason that there will not be a surplus of steam sizes, which has been the cause of some idleness on account of unbilled steam coal.

In the Mt. Olive field conditions are about as normal as in any field in the state. The car supply is fairly good, labor is holding out remarkably well, and the production about equals the demand. In the Carterville field a car shortage still continues, and the mines are not getting anywhere near the time that they should, even with their reduced tonnage. The railroads continue to draw heavily from this field, despite rumors to the contrary that this condition would be eliminated for the time being at least. There has, however, been a little more free Carterville during the past week than for some time previous, but little of it is coming into the Missouri market.

There is not likely to be any disturbances in labor conditions for the remainder of July in this field, but the inroads that the draft will bring in August and September will cause a further decrease when there should be an increase in tonnage.

The conditions in the Duquoin field are somewhat similar to those in the Carterville field. There are no eastern coals coming into the St. Louis market at all, with the exception of a few cars of Ayershire, Ind., and other coals for gas-producing or gas-making purposes.

One unusual feature in the local market is that there seems to be a surplus of Big Muddy coal from the Murphysboro district. A little Arkansas has moved in the past week, and some outside gashouse coke, but the local market is one that has got to depend practically from now on upon the coal from the local Illinois mines.

An order has been issued that all operators and jobbers shipping coal into Missouri should make reports of such shipments to the Local Fuel Administration, so that they may keep check on the tonnage put into each locality.

The retail market holds up to the maximum for July, which is: Elkhorn Laclede and St. Louis Elkhorn byproduct coke, $12.75; Carterville lump, egg and nut, $6.20; Duquoin, $5.95; Mt. Olive lump, $5.70, and Standard lump, $5.45.

The market in carloads is:

	Williamson and Franklin County	Mt. Oliv and Staunton	Standard
6-in. lump...	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg..	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut..	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut....	2.55@2.70	2.55@2.70	.....

3-in. lump...	.....	.....	2.25@2.40
2-in. lump...	.....	.....	2.25@2.40
Steam egg...	.....	.....	2.25@2.40
Mine run....	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1.....	2.75@2.90	2.75@2.90	.....
No. 2.....	2.75@2.90	2.75@2.90	.....
No. 3.....	2.55@2.75	2.55@2.75	.....
No. 4.....	2.55@2.75	2.55@2.75	.....
No. 5.....	2.05@2.20	2.05@2.20	.....

Williamson and Fronklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

General Statistics

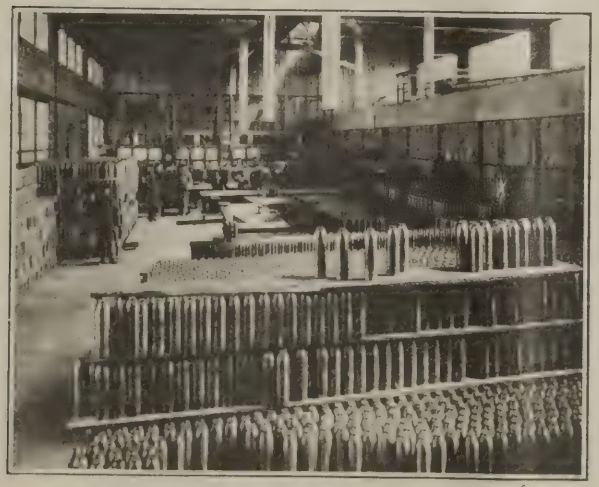
NORFOLK & WESTERN

Below is given a statement of the coal tonnage from mines on the Norfolk & Western Ry. and from other railroads, for the month of May, 1918.

From:	Net Tons
Pocahontas field	1,505,115
Tug River field	310,860
Thacker field	281,929
Kenova field	103,171
Clinch Valley field	141,816
Other Northern and Western fields	12,918
Total Northern and Western fields	2,355,809
Williamson & Pond Creek R.R.	181,832
Tug River & Kentucky R.R.	57,641
All other railroads	81,700
Grand total	2,676,982

COAL AGE

Volume 14 New York, July 25, 1918 Number 4



The Interpretation

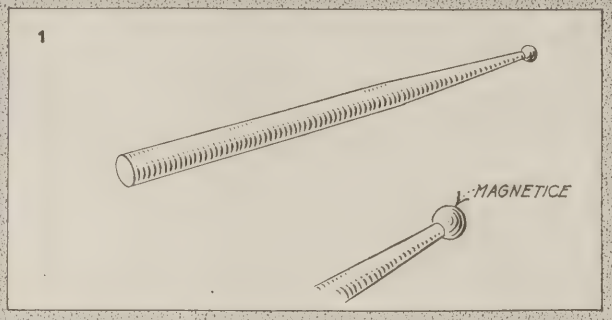
Written expressly for "Coal Age"

By RUFUS T. STROHM

FORGET that coal is a stony mass
That grimes the breaker and chokes the screens,
And try to think, as you watch it pass,
Of all that its shiny blackness means;
For when you see that it's tons of steel
For shell and rifle, for wheel and rail,
For plate and armor, for rib and keel,
You will not falter, you dare not fail!

EACH time your shovel completes its round,
The coal that over it slides and runs
Will make steel bullets enough to pound
The daylights out of a hundred Huns;
And four such shovelfuls represent
The polished form of a three-inch shell—
The pointed sort of an argument
That Yankee fighters can handle well.

"Four shovelfuls of coal represent the polished form of a three-inch shell"



Copyright by Committee on Public Information

The boys who go "over the top" in France offer their lives. Can we at home offer less than our full-time labor?

A FULL day's yield of a mine will feed
The flaming maws of a transport ship
That cuts the sea at a greyhound's speed
With an army corps at a single trip;
But it takes the coal that a mine can turn
In the space of six or seven days
To build that vessel from stem to stern
And send her slithering down the ways.

WITH every stroke of your flying pick,
With every blow on the ringing drill,
You're doing your own small part to lick
The 'tarnal tar out of Kaiser Bill;
For coal is the thing that will stem the tide
And write the end of the bloody tale,
So, while we battle with Prussian pride,
You must not falter, you dare not fail!

Utility and Value in Cases of Emergency

Coal, Explosives, War—I

By H. J. BROUGHTON
Wilmington, Del.

SYNOPSIS—*This article is the first of a series of three on this subject. It sets forth the relation that coal bears to business in general and the conduct of war in particular. Coal is of such prime importance that all means possible should be employed to increase its production. The careful and intelligent use of explosives may be made a potent factor to this end.*

EVERYWHERE has been heard the call for efficiency, conservation and coöperation, owing to the stress of war which has laid new requirements upon the country and upon industrial organizations. No more beneficial thing could be proposed than efficient conservation by coöperation, to avoid waste and promote production of coal.

Without coal we cannot wage war, cannot progress in manufacture nor can we live with any degree of comfort. Coal is one of the most commonplace articles with which we come in daily contact, yet at the same time one of the most important. Its possession by a community or a nation means comfort and progress, and simultaneously a strong strategical position from a military standpoint.

The equivalent of ten tons of coal a second is running to waste over Niagara while "Speed Up Coal Production" is being agitated. Niagara is only one instance of waste energy. The streams of this country in which millions of horsepower are running to waste every day could be made a perpetual source of wealth and prosperity.

When we hear of a cathedral or other work of art being blown to atoms, or an almost priceless bronze statue being melted up to make bullets, we are likely to think it a shame. It would be much less a shame to harness the power that is now going to waste in streams that in thousands of cases are merely beautiful sights to be gazed upon, while we go hungry for the things their power would supply. Many trains could be driven by the energy of the restless mountain streams without seriously affecting their attractiveness or in any way detracting from their beauty.

Another enormous saving of coal could be accomplished by using the million of feet of lumber, the millions of cords of wood that are now being wasted, not only in the form of cut and standing timber, but also in the form of stumps. This has developed into such a momentous question that it will be only a matter of time before the Fuel Administration will take a hand in its solution. The Ohio Fuel Administration has already announced that shipments of both hard and soft coal to communities where there are no essential war industries may be stopped entirely.

On our farm lands in every direction is an immense supply of wood waste, in wood lots and stumps without number. Particularly in the case of the latter have we a fuel supply that is cheap, ready at hand and abundant.

Many hours could be saved by the consumer in unloading coal from the cars as soon as they arrive at their destination, could he be brought to the realization that every hour saved may be the means of saving a soldier's life in France. Millions of tons of coal could be produced, but it could not be moved at this time for want of cars; and the time wasted in unloading the cars makes a surprising total when the number used for this purpose is considered.

When electric generating stations are located at the mines, doing away with the transportation of much power coal, we will have accomplished something worth while. All railroads could be electrified, factories operated from central distributing stations and isolated plants abolished.

Our present-day boilers and furnaces are inefficient in getting the biggest percentage of heat out of coal. Newer apparatus that can burn poorer grades of fuel are needed badly. This would tend to conserve a large amount of the supply. Many owners of plants using coal are sleeping a dreamy sleep, dreaming that their plants are efficient, that they are getting the greatest possible percentage of energy from their coal. When they awake and find how much real money they could save by using a little of it now, to increase the efficiency of their coal-consuming apparatus, they will wish they had set their alarm clock for an earlier awakening.

By not properly insulating steam pipes last winter

much steam went to waste that otherwise could have been used to advantage just at the time when coal was needed most vitally. Next winter should see every exposed pipe covered with the proper amount of insulation. The saving thus afforded would pay for many a ton of coal, but the initial expense of installation seems to bother many a man otherwise cautious.

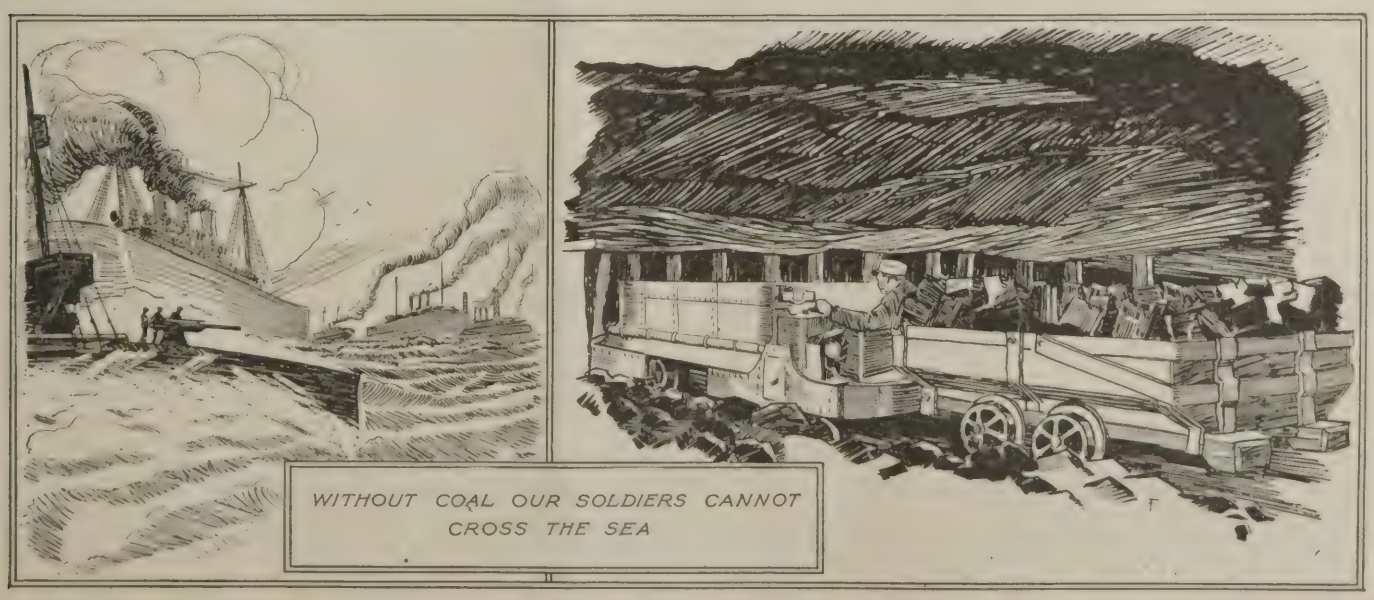
So when we see a lump of coal and consider its immense value as a force in civilization, and realize how practically all industry at present depends upon this fuel, we can look a little farther and perceive that at the present time our production of coal depends largely upon explosives; but of equal importance is how these are employed. When properly used, they result in a greater quantity of coal being produced with less effort. This means a conservation in man-power.

Every effort is apparently being put forth by the coal operators, the miners' organizations and the individual miner, but closer attention to details will work wonders. And if the householder is to be kept warm, while our ships, railroads and factories run at war speed and ordinary business proceeds without lessening its forward trend, more attention to blasting details must become the rule at the mines.

The welfare of our country depends upon those who have learned, or will learn, to do in the right way the things that are to be done. Just now the demand for production has overcome time-honored rules and ways of doing things in every form of industry, coal mining included. More direct and more efficient methods must be adopted, and the stereotyped way improved upon. The great question that every miner must ask himself is, "Am I going to embrace this opportunity to be of service to my country in its hour of need, or am I going to dodge the issue and go on with my work as usual?"

Every miner's reputation is at stake. The greatest prosperity the world has ever known will be the lot of this country after the war, and the men who have hung back and have not tried to do their utmost are the ones that will suffer for what they have failed to do. The man with the reputation for doing things is the man who will gain in the end. He who pays a little more and unusual attention to performing his work better right now than he has ever done before will be the man remembered by his superiors when peace comes.

The miner is going to be just as instrumental in winning this war as the soldier and sailor, with the exception that the miner will not be called upon to risk his life; for there is little need of risking his life in his daily occupation if he will but study improved methods of doing his work. It is his patriotic duty to do so. It is either face this fact now, or duck and dodge and be called upon to suffer later.



In a recent statement Frankin K. Lane, Secretary of the Interior, said: "Our three-quarters of a million coal miners produced 644,000,000 tons of coal in 1917, an increase of 54,000,000 tons over the previous year, notwithstanding transportation conditions in certain regions were worse than ever before in the industry. The increased output of war-making materials shows very clearly how faithful, how energetic, how patriotic has been the army of miners upon whose efforts depends our production of these vital supplies. . . . If the demands increase this year, our efforts will also increase. What we must achieve we shall."

Many Men Taken by the Draft

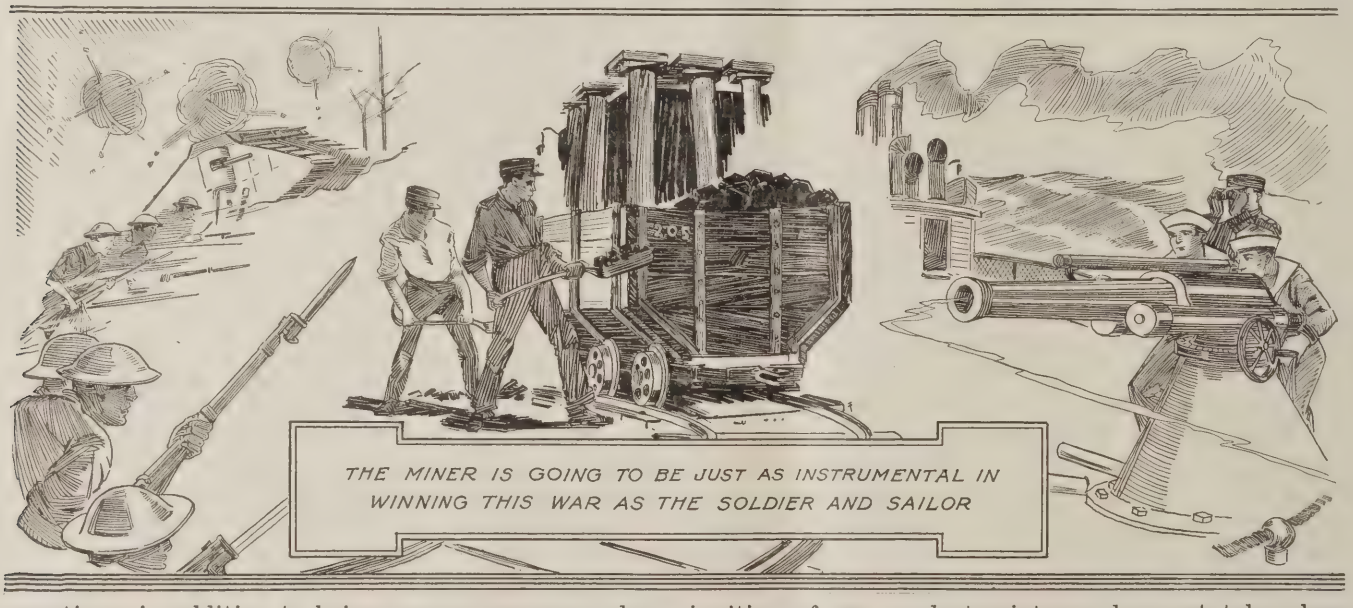
The call to the colors has taken many men from the mines. Alien coal diggers have flocked in great numbers to the land of their birth; the draft has drawn away countless others, while many more have been attracted by wage inducements offered by the industrial concerns engaged in the manufacture of war supplies.

If additional labor cannot be secured, more efficient methods of production must be practiced. One of the greatest of these is the proper use of the means we have at hand, by men who are patriotic enough to take a sufficient amount of pride in the increased production to warrant their search for, and use of, more efficient methods of employing explosives in blasting coal. Close attention to the details offered by the makers of explosives in the various handbooks of instruction published by them will do much toward relieving this situation.

In many places the men are laying off three days a week, and only working enough to insure their ordinary wage. That there is a shortage of labor is no excuse for those now engaged to lay off and become slackers. The Government should take a hand in this matter and draft the services of the men and compel them to work full time, as the soldier and sailor have to do. Without

coal our soldiers cannot cross the sea. More coal must be produced, hence the miner should try to do more than his ordinary share.

Another way in which the miner can be of great assistance is by paying particular attention to the amount of "gob" that he allows to come up with the coal. It takes just as much power to transport this useless mess as it does to carry clean fuel. For every pound of slate delivered to the consumer, a pound of coal will later have to be delivered, that he may get maximum production. Every bit of gob going into the firebox means just so much added to the destruction of the grates. Industry can speed up, railroads can haul more and use less fuel, warships can make faster headway, every manufacturing plant can multiply production if clean coal is the rule and not the exception. This is up to the miners, who must see to it that the coal is at all times loaded clean.



Unfortunately, in the mining of coal a great deal of inflammable gas is encountered, this amount varying in different localities. Some of the mines are filled with gas pockets so that their upper workings are full of an inflammable mixture of gas and air. Some of these operations, in addition to being gaseous, are very dry, and the dust from the coal fills the air. The combination of these two—the gas and the dust—makes a mixture which is not only easy to explode, but in which detonation when once started becomes self-propagating throughout the mine workings. Such an explosion nearly always results fatally.

The great development of the mines, caused by the demand for fuel, drove the operators to seek coal that lay far below the surface. This necessitated shafts into gaseous territory, with headings driven miles from the openings, requiring thousands of cubic feet of air to supply the miners. The air gives them life and strength, but at the same time absorbs the moisture, dries out the mines and makes the dust more inflammable. This dust is easily placed in suspension by a passing trip, or a heavy or windy shot, which may short-circuit the air. Then comes a "blowout" shot with its terrible results that make one shudder and wonder that some means have not been taken to lessen the toll paid for the mining of coal. True, thousands of tons of coal have been mined without this awful price; even mines known to contain gas and dust have been operated for years without an explosion. But is this because of good management or is it just luck?

It must be remembered that not all coal mines are gaseous and dusty, and vast quantities of blasting powder are used today in producing lump coal in mines which are practically free from gas and which are so wet that dust does not hang in the air.

Gas and dust explosions in England, France and Belgium became so frequent that chemists were set to work to devise some explosive that would give a shorter and cooler flame than that produced by black powder. These researches eventually resulted in the production of what are known as "safety explosives," or "permitted explosives," in the United States. In Europe the national authorities designate what explosives shall be used in the coal mines, whereas in the United States the national government only specifies which explosives are recommended for use in dangerous coal mines.

Permissible explosives, when properly used in accordance with the instructions furnished by the manufacturers and the United States Bureau of Mines, give a flame of such short length and duration that ignition of gas or dust mixtures does not take place. Not only this, but the fact that these explosives are made up in cylindrical form and do not have to be either poured or broken, makes their handling much safer than that of black powder—contrary to the popular notion.

Permissible explosives, being a first cousin, as it were, to dynamite, it would naturally seem that they would be more dangerous to handle than black blasting powder; but such is not the case, as they are very difficult to ignite—that is, they do not burn readily—and for their explosion require an intermediate agent known as a "detonator," or "blasting cap." They are also much less sensitive to detonation than is dynamite and require a powerful detonator to completely explode them.

A permissible explosive is defined as follows: "An explosive is considered permissible for use in coal mines when it is similar in all respects to the sample that has passed the tests required by the Bureau of Mines and when it is in accordance with the conditions prescribed."

It is generally understood that a permissible explosive should be used in all those coal mines containing dust and gas; however, there are difficulties to be overcome in this connection. The greatest difficulty is the prejudice of both the operator and the miner. The next is the improbability of being able to induce the miner to use the explosive in such a manner as to get its greatest efficiency. It can be shown that in using permissible explosives the operator is buying the cheapest kind of mine insurance. The miner also, in using permissible explosives, is gaining the cheapest kind of life insurance.

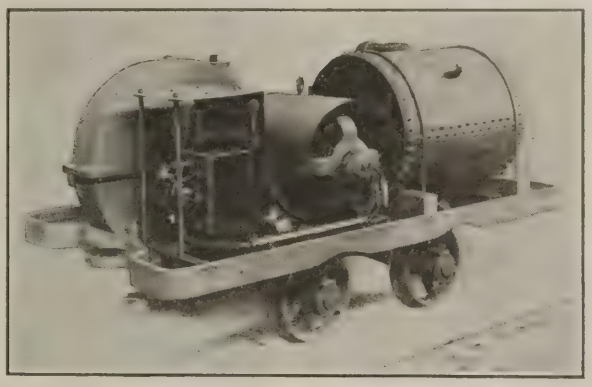
At a great many collieries the miners make a habit of using the "combination shot"—that is, using black powder and dynamite in the same borehole. This pernicious practice has always been the great objection against the use of the better grade of permissibles, owing to the fact that a good permissible will not satisfactorily detonate when black powder is used as a detonating agent. Consequently, until a definite stand is taken against the use of the combination shot by the operators, and also by the mine inspectors, little progress can be made toward increasing the use of permissibles.

When mine operators come to a realization of the necessity for protecting their men, they will squelch the combination shot and absolutely enforce the use of permissibles, or black powder with electric firing. The use of electric blasting caps with permissibles is recommended for the reason that all miners are in a safe place before the shot is fired and the risk is not run of hang-fire from a piece of fuse that does not burn properly.

The proper placement of boreholes and the use of the right explosive assure a maximum production and avoid the necessity of either redrilling or drilling extra holes in making the original shots, in this way saving much labor in boring. The first cost of permissibles to the miner is a trifle higher than that of blasting powder, but if it were possible for him to fully appreciate and realize the safety feature, the difference in the air, saving in time in allowing him to return to his work and the lessening of falls of slate from a broken roof, he would gladly pay the difference.

The blasting of coal with black powder in the presence of gas and dust mixtures is dangerous. Black powder produces a long, hot flame from the charge in the bore, which instantly ignites any gas or dust present.

The flame temperature of all explosives is above the ignition point of inflammable gas and dust mixtures, but the flame of a permissible explosive is of such short duration that under the conditions of blasting down coal it does not ignite the gas and dust present. There is only one plausible reason for not using permissibles, and that lies in the preparation of the coal. It cannot be denied that coal shot with permissibles is racked more than when shot with blasting powder, but in many instances this is caused by misuse of the explosive, or by not selecting the one best suited for the coal. Sometimes a fast powder will give a better coal than a slow one, but proper undercutting with properly placed holes should give a good-sized lump without an excessive quantity of slack.



(To be continued)

Portable Motor-Driven Compressor for Mine Use

It has been said that coal will win the war. Therefore, anything that will help to increase the production of this fuel is of interest, not only to the mine operator but to the whole nation as well.

A useful machine in this connection is the small portable compressor manufactured by the Ingersoll-Rand Co. for mine service, either as an auxiliary to the main compressed-air system, or for development work in operations without compressed-air service. It can be used for operating drills, coal cutters, air lifts and for other purposes. The complete outfit is mounted on a truck with flanged wheels of a gage to suit the mine track, and can be hauled wherever needed.

This type of compressor is made in capacities up to 415 cu.ft. of air per minute and for pressures up to

PORTABLE COMPRESSOR FOR OPERATING DRILLS, COAL CUTTERS AND AIR LIFTS

100 lb. The motor, which is built by the Westinghouse Electric and Manufacturing Co., is designed to operate on the available current, and is furnished in sizes ranging from 12 to 56 hp., depending on the capacity of the compressor. A large air receiver forms a part of the outfit. Into this the air is pumped and the pressure therein is automatically maintained constant.

Compressor at Coal Mine

There are nearly always opportunities for operators to pick up bargains in second-hand machinery by watching the advertising columns of technical and trade papers. A progressive Illinois coal man recently, in commenting on this subject, pointed out the advantages of having a small compressor at his plant. He had purchased a small second-hand air outfit, set it up at his mine shop, and it is now doing good service.

Many of the numerous small jobs around a coal plant can be facilitated by power machinery. Possibly riveting is to be done on a cage, on the steel framework of the tipple, or other metal work. Holes are to be bored in heavy timber or drilled in metal away from the shop. As part of the shop equipment, the air lines may be extended to various nearby points about the plant to furnish power when needed. The operator in question considers the use of live steam too expensive a means for blowing off boilers—he utilizes compressed air for the purpose. Like many another facility, its application multiplies with the many opportunities afforded for its use.

Conservation of Miners by Employment of Mechanical Equipment

By R. L. HERRICK, M. E.
New York City

MINE-LABOR shortage is the "bugaboo" of the anthracite district. Recent drafts to the army have aggravated an already bad labor condition. Before the draft many mines were running with mine crews depleted from 15 to 40 per cent. from those of normal pre-war times, and now the production of anthracite threatens to ebb to a new low mark. The mining situation presents a curious discrepancy, however, that may well be noted. It is this: While the loss of many men has adversely affected the production of some of the largest and oldest mines of the district, others with similarly reduced mining crews have actually increased their tonnage investigation into the causes of this discrepancy has led me to the conclusion that the gain or loss of tonnage is largely a question of mechanical equipment. Those mines which have held their tonnage output to about normal—or if anything have increased it—have installed modern machinery equipment which has conserved the man-power of the organization. Instances are common where the installation of certain machines has made what was formerly heavy labor now easy on the men, and at the same time allowed one or two of them to do the work formerly requiring the united efforts of from six to eight. It is, of course, understood that the men thus released from routine work have been immediately transferred to the vitally important work of getting out coal.

FIGS. 1 AND 2. THE SMALL DRILL IN THIN COAL

In what follows it is proposed to give typical examples of such man-power saving as have come under my immediate observation in the course of a 450-mile automobile trip about the mines in various parts of the anthracite district. For the figures upon which various statements are based, I am indebted to an engineer intimately acquainted with the district through long residence—William Wilhelm, Scranton manager of the Ingersoll-Rand company. To what extent will it pay to replace hand with machine drilling? The anthracite operator is squarely face to face with this issue to-day. And upon his answer to that question largely depends the amount of man-power conservation he will be able to effect. In general terms it may be stated that coal is ordinarily machine-drilled in say from one-fifth to one-sixth the time that the same holes can be put in by hand. The hardness, dampness and physical properties of the coal vary widely in different parts of the anthracite district, and all of these conditions affect the speed of drilling. Thus in some sections the hand drilling of a 6-ft. hole requires say 10 min., while in

FIGS. 3 AND 4. ILLUSTRATING THE USE OF JACKHAMERS IN A THICK COAL BED

FIGS. 5 AND 6. CHANGES IN A BLACKSMITH SHOP FROM USE OF DRILL STEEL SHARPENER

others it cannot be done in less than 30 min. In general, therefore, the same holes will require only say 2 to 6 min. when drilled by machine.

On the face of the situation thus presented there could be no question about the advisability of universally adopting machine drilling. But actually there are a number of other considerations which influence the operator. Perhaps one of the elements most vitally affecting the problem is the fact that in most of the large operations the miner is practically a free agent. He is paid by the ton of coal, or yard of advance in rock, and his hours of work are advised, but not dictated, by the mining companies. In addition to this, the miner owns his own tools, although he may be financed by the operator to enable their purchase.

FIG. 7. TAKING UP BOTTOM

Under such conditions it is only natural to expect that machine drilling of coal is in vogue only where the mining conditions themselves caused the miner to employ drills in order to make, what are to him, satisfactory wages without a great deal of unnecessary hard work and in a satisfactory number of hours of labor.

So far mining conditions have made immediately advisable the adoption of machine drilling only in thin beds of comparatively small pitch. War conditions such as high price, etc., have enabled the working of such beds at a profit. Hence, in thin measures we find machine drilling of coal naturally making its first big progress of supplanting hand drilling. This is not meant to imply that in thick beds progress with machine drills has not been large, but only that this progress has been comparatively greater in thin beds. Some of the reasons for this condition are made plain by contrasting Figs. 1 and 2, showing thin-seam mining, with Figs. 3 and 4, which illustrate conditions in much thicker beds of coal. Fig. 1 shows the drilling of a bottom hole in an anthracite bed which is only 20 to 24 in. thick. In this case a plank is used on which the Jackhamer is slid along. Fig. 2 shows another view in this same bed, using a JC-40 drill mounting. The bottom of this bed consists of 6 in. of bone and is consequently exceedingly hard to drill.

Such beds as this were practically impossible cer-

FIGS. 8 AND 9. SMALL HOIST HANDLING PIT PROPS AND LOADED CARS

tainly unprofitable, to mine with the old hand-auger drilling method, but have been made profitable with machine-drill methods which produce a good tonnage per day.

Fig. 3 shows the drilling of a horizontal hole in the Dunmore vein, which, as plainly shown, consists of alternating bands of coal, bone and slate, making up a total thickness of about 6 ft. Such a bed is hard to drill by hand, and hence the favor shown to machine drills. Fig. 4 shows taking up the rock bottom with a $\frac{7}{8}$ hexagon steel replacing the twisted bit in the same drill shown in Fig. 3.

An example will suffice to still further clarify the situation: A coal bed 30 in. thick is mined in the Scranton district by rooms 30 ft. wide. The coal face is attacked by say from 11 to 14 holes, drilled about 6 ft. deep, which should blast down 450 cu.ft. of material, netting say 16 tons of coal.

The hand-auger drilling of these holes will require an average of say 30 min. to the hole, thus requiring 6 or 7 hours of labor. The machine drilling of these holes will take only from 55 to 70 min. to complete, although these are by no means the quickest figures on record.

Figs. 1 to 3 all show the use of twisted cruciform steel in connection with the Jackhamers. These machines differ in no way from the standard drill striking a hammer blow, but the use of twisted steel allows the standard drill rotation to produce an auger-like effect in the holes, thus rapidly clearing them of pulverized coal (clearly shown in Figs. 1 and 2 beneath the steel).

The use of this cruciform steel has rapidly grown in favor, especially during the past year in the Scranton district. It was originally furnished by the manufacturer in sizes to accommodate the usual diameter of black powder cartridges. But in response to the demand for hand-drill outfits in other districts, where Monobel powder is in use, another size of twisted steel is being manufactured and will soon be available.

For the mining of thin coal beds the drill mounting shown in Fig. 2 has proved a boon to the miner. In fact its lightness enables quick movement from place to place, while its operating features reduce the miner's drilling job to a sinecure. He has only to push the drill straight ahead, and it practically runs itself.

Aside from being easier than hand-holding upon the drill operator, the mounting performs the double function of providing a steadyrest in starting and pointing the hole, and that of furnishing a support during the drilling. Without such a support the average miner lets the drill practically hang upon the drill steel after the latter has advanced 6 or 8 in. into the coal. The support afforded by the mounting has been found to practically eliminate drill steel breakage arising from this cause.

FIG. 10. A SHORT STEEP GRADE

While machine drilling of coal is apparently most common in the thin beds, and in those thick ones whose bone and slate layers make hard hand drilling, it has a great future in the thick and easily hand-drilled seams. Wartime conditions seem certain to hasten the coming of that future.

The visitor to the various mines of the anthracite district is somewhat puzzled to account for the facts as he sees them. For instance, in many thick and easily mined beds he finds the Jackhamer busy, as shown in Fig. 7 taking up the rock bottom. For rockwork nearly every mine in the district has such machines by the score. But when it comes time to mine the coal, the miner picks up his hand auger and goes at it. This may not be the rule, but I saw it often enough throughout this district to be impressed by its frequency.

For example, in the case of the mine shown by

FIG. 11. THREE SMALL HOISTS PULLING CAR UP GRADE SHOWN IN FIG. 10

Fig. 7 the coal bed was 8 ft. thick, had a high pitch, and the coal itself was comparatively soft. The miner could drill his 8-ft. holes in about 10 min. each by hand auger, and could completely drill his room in about two hours. Under the present working conditions he could bring down in a few hours all the coal by hand that his one "buddy" could load in a day.

FIG. 12. PORTABLE AIR COMPRESSOR UNIT

Those few hours enabled him to quit about noon well satisfied with his usual day's wages.

This particular miner was not interested in the machine drilling of coal, and for obvious reasons. This illustrates the perplexing problem some mine operators face today. The present situation may, in fact, be paraphrased as this: "One miner, one auger and one buddy." Why should it not be: "One miner, one machine drill and four buddies?"

Is there any reason why the miner should not acquire greater dignity as the employer of four helpers instead of one, and make increased mining profits in proportion? Must the correction of a decreasing coal production be impeded by the old-established custom of having one buddy only? Upon the answer to these questions may hang the fate of nations!

Suffice it to say that it is believed that under changed conditions a machine-drill miner can easily replace four hand-auger men in thick beds and thereby allow the saving of three miners, thus made available for either increasing the coal output or filling the gaps in the ranks of the buddies drafted into the army. Fifty hand-machine drills installed in a mine should result in a man-power conservation equivalent to 150 miners per day.

Many of the coal-mining companies of the anthracite district have greatly increased the number of hand-machine drills employed underground during the past year. As a result, an increased burden of steel sharpening has been thrown upon the blacksmith shop.

The sharpening of hollow drill steel by hand is a comparatively slow and unsatisfactory method. In the average shop a blacksmith and helper will hand-sharpen about 35 to 40 seven-eighth-inch hexagon steels per day, depending upon their condition. And since the blacksmith must rely solely upon his eye for gaging, he usually makes a gage interval of about $\frac{1}{4}$ in. between successive steels of a drill set in order to insure against sticking. This handwork is so slow that frequently defects develop in the bit due to its cooling before it is properly shaped.

With the increased demands upon the blacksmith shop for steel sharpening, many mining companies started the installation of Leyner machine sharpeners. These have proved one of the most pronounced labor savers introduced into the district. The situation before and after the installation of one of these sharpeners in one of the largest shops of the Scranton region is shown by Figs. 5 and 6.

In this shop there are four forges employing four blacksmiths and four helpers. Fig. 5 shows one side of this shop with the men employed at the hand-sharpening of steel. Fig. 6 shows this same shop after the installation of a machine sharpener. The operator of this machine did all the steel sharpening of the eight men and turned out a large amount of routine blacksmith work in addition. The seven men thus made available were badly needed at other work about the mine and were so utilized.

Aside from this labor-saving feature of the machine sharpener the bits themselves are far superior to the hand-made ones. Owing to the perfection of bits, made inevitable by the machine's gaging, it was possible to reduce the gage interval between steels to $\frac{1}{16}$ in. instead of the $\frac{1}{4}$ in. as formerly. This results in greater drilling speed in the mine.

This machine sharpener is equipped for making the shanks on $1\frac{3}{8}$-in. twisted cruciform steel. Besides its common work of shanking and sharpening steels, it is admirably adapted to blacksmith work of many kinds, such as making boltheads, and even drawheads for coupling mine cars. Some of the mines have fitted up these sharpeners with dies for making mine-car couplings, which work is being done with great rapidity.

In many sections of the anthracite district, particularly where the coal beds are of steep pitch, the movement of mine timbers into the upper workings presents a real problem. In such places the Little Tugger hoist serves a double purpose—that of supply-

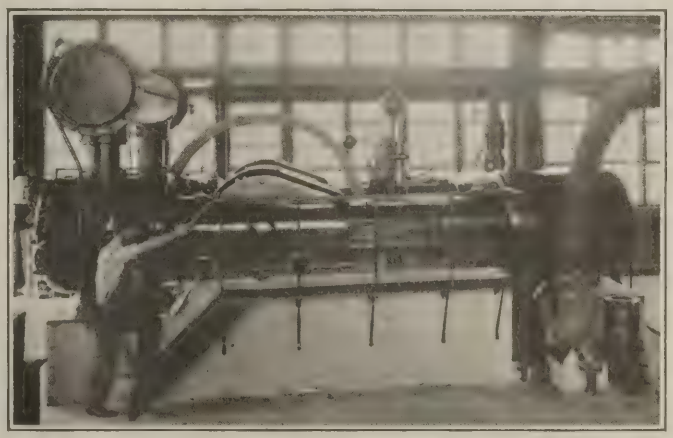


FIG. 13. A MODERN AIR COMPRESSOR ON THE SURFACE

ing the needed tractive power and furnishing air for ventilation.

A typical installation of its kind is shown in Figs. 8 and 9. In one section of the Catherine colliery of the Trevorton Coal Co., the Lykens No. 2 vein pitches $15\frac{1}{2}$ deg. and the steady movement of timbers up such a steep slope taxed the endurance of the men formerly

employed on the job. A slope 250 ft. long connected two levels. Up this the timber was moved, and down it was discharged the coal extracted in the development of the upper level.

The development of four rooms and two gangways required six mine-car loads of timbers per day, and for carrying up the timbers by hand six men were formerly employed constantly.

Fig. 8 shows the Little Tugger hoist recently installed in close quarters at the head of the sheet-iron-lined timber chute. Its $\frac{5}{16}$-in. wire rope is pulled down into the lower level, where one man attaches it to the timbers on the cars. On signal, the hoist then pulls up from three to four timbers 14 ft. long and averaging 8 to 10 in. in diameter. The ropeman rides the timbers to the upper level and returns with the slacked-off rope.

The timber is thus hoisted with only one man in addition to the hoist operator. These two men thus accomplish, in one-half day, the work formerly requiring six men all day. The other four men are accordingly available where badly needed for getting out coal. The hoist, therefore, performs the equivalent of eight men's work per day.

The hoist has a speed of 85 ft. per min. in lifting a maximum weight of 1000 lb. vertically, but in hauling these heavy timbers 250 ft. up the slope, about 5 to 6 min. are required for the round trip by the ropeman.

When not in use for timber hauling, this machine is available for hauling coal in a one-ton buggy from the face of the level along a slight grade, to the rocker dump at the head of the chute. Fig. 9 shows the loaded buggy approaching this discharge point.

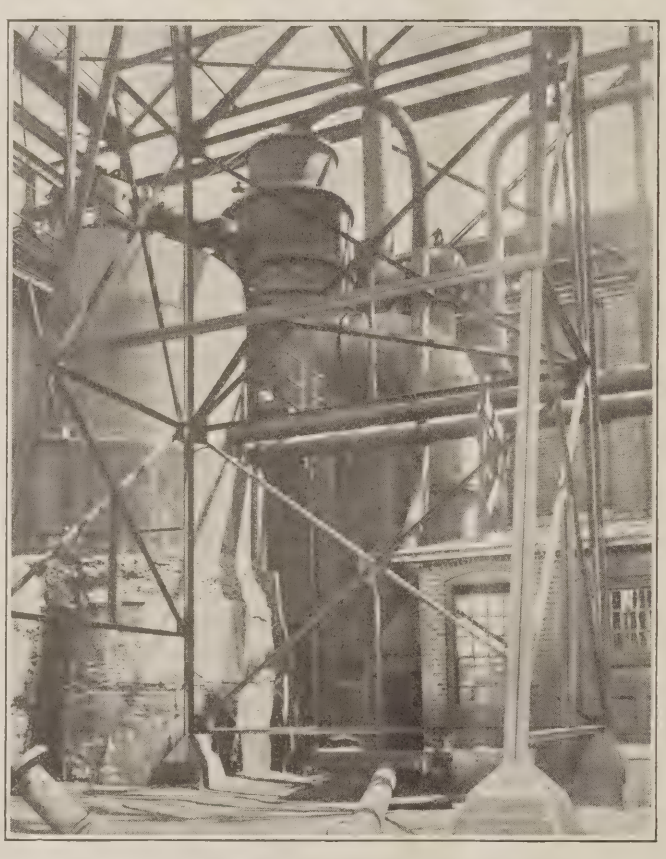

FIG. 14. AN ACID-RESISTING CONDENSER

Scores of these hoists have already been installed in many mines of the anthracite district. They are used for a wide variety of purposes, such as, for instance, the hoisting of rock in buckets from shallow shafts, the hoisting of tools and men into raises, and even pulling 40-ton capacity empty coal cars up a slight grade to a loading position beneath the discharge chutes of a breaker.

At another large colliery an unusual installation of these machines shows their strength as well as adaptability. In driving a rock tunnel to connect with a shaft, it was desired to use the 108-cu.ft. capacity cars, standard about the mine, to receive the rock mucked from the face. The rock tunnel connection was about 300 ft. long and had only a slight grade except at one point—shown in Fig. 10—where for about 50 ft. the track was given a grade of 10 per cent.

The 108-cu.ft. car loaded with rock weighs about 12,000 lb., and to pull it up the 10 per cent. grade three hoists were installed, as shown in Fig. 11.

The concentration of three separate hoists pulling three ropes attached to one heavy car is, of course, rather unusual and would not often happen except in emergency cases, and then only for temporary work. This installation serves to forcibly illustrate, however, the extreme flexibility of these machines, and the possibility of tiding over, with them, a situation where the delivery of a powerful single hoist under present conditions would seriously delay urgently needed mine development.

I have noticed a large number of installations of these little hoists in the anthracite district. In each case the machine did the work formerly requiring from six to eight men. Assuming, however, that each one effects a man-power conservation of at least four men, twenty such machines effect a conservation of at least eighty men. There are a number of companies throughout the district which have installed this many machines or even more.

In the foregoing, mention has been made only to man-power conservation made possible by increased coal production due to machinery. Another phase of the same problem is the decreased coal consumption of the mines themselves, due to improved equipment for power production. This brings us to the subject of improved machinery for compressing the air utilized in all the machinery mentioned above.

Anthracite operators may, for descriptive purposes, be divided into three classes as regards their method of compressing air. The first and possibly largest class depends upon small portable units installed underground. The second class depends wholly upon large central surface compressor plants, and the third class, in which there are comparatively few, depends upon both surface and underground units. For instance, one large company has several scores of portable compressors underground, but is at the present time installing several surface units.

Referring to the small portable compressor machinery underground, the most popular machine in the district is the Ingersoll-Rand mine-car type, shown in Fig. 12. These cars are moved about from point to point in the mines and are usually placed in some niche or out-of-the-way spot from which the air can be conveniently piped to the drills. When hose is employed for air transmission, the compressors are usually placed within 200 to 300 ft. of the drills; but frequently the air is piped as far as 800 to 1000 feet.

These portable compressors are made in several sizes capable of furnishing air from two to eight hand-machine drills, their equivalent in Radialaxes and small hoists. The compressor cars carry a water-cooled compressor, its driving motor, air receiver and automatic starting rheostat. To connect with the power system it is only necessary to hang the bare end of the cable over the trolley wire at some convenient out-of-the-way point. Any laborer can start the compressor without danger to either himself or the machine by simply throwing an ordinary knife switch. He can then go away and leave the machine running and, except for daily attention in filling the compressor hopper with cooling water, it needs no further care since lubrication is automatic.

If by reason of stopping all the drills the air pressure rises to a predetermined pressure limit, the air intake is automatically closed, thus cutting off the load on the machine and reducing its power consumption until such a time as the drills are again operated, when the automatic opening of the intake again allows the compressor to carry the load.

The obvious advantages of such an installation are the saving of transmission losses incident to long lines and the saving of power at all times, except when the drills are actually running.

In the case of the mining companies who produce their compressed air in surface plants and pipe it underground, their compressor economy is undoubtedly superior to that attained in the small portable units.

Many Surface Plants Have Been Remodeled

During the past year many of these surface compressor plants have been completely overhauled and reëquipped with modern machinery capable of making notable savings in coal.

A new compressor plant typical of a large number of installations in the district is shown in Fig. 13. This illustrates an Ingersoll-Rand, Type XPV, size 18 & 29 and 26 & 16 x 20-in. stroke. It has a rated capacity of 1955 cu.ft. of free air per minute, develops a maximum of 344 i.-hp. and has a steam consumption of only 15 lb. of steam per ½-hp.-hr. running condensing.

This type of compressor has a number of notable features, but they may all be summarized by saying they give practically a Corliss steam economy for less than Corliss first cost. This is due in large measure to their piston valves, which are especially adapted to the use of high steam pressures and superheat.

Many of the old compressors, which newer equipment recently displaced, compressed the air in a single stage and operated noncondensing. A brief example from actual practice will serve to illustrate the coal economy made possible by the installation of these new compressors having two-stage air compression, steam compounding and run condensing.

The old compressor required 129 lb. of steam per 1000 cu.ft. of free air actually delivered at 100 lb. pressure. The new compressor required only 68.3 lb. of steam per 1000 cu.ft. of air when operating noncondensing, and only 50.6 lb. of steam per 1000 cu.ft. when run condensing. The difference in steam consumption between the old compressor run noncondensing and new compressor operated condensing, for equal delivery of air, is 80,800 lb. of steam per 10-hour day. This saving, expressed in terms of fuel consumed at the rate of 1 lb. of coal per 5 lb. of steam, is 16,160 lb. of coal per day.

To furnish the air required for fifty Jackhamers, two such compressors would probably be required whose saving over former compression methods would be at least 16 tons of coal per day. This is equivalent to the coal productions of two men per day from some thin coal beds.

Can Mine Water Be Utilized?

The majority of mines in the anthracite district produce rivers of water from their drainage systems which are not utilized in condensing plants because of their acid nature. The condensing problem seems to be peculiarly difficult in the Scranton district, where the mine water is strongly acidulous and boiler water must be purchased from city mains.

Considerable experimenting with various types of condensers has been conducted by one company during the past two years, with the view to finding a way to utilize its mine water. All the condensers tried inevitably ended on the scrap heap after about 90 days' corrosion by the acid water, until finally the Beyer condenser shown in Fig. 14 was installed. The steel craneway shown in this illustration was doubtless built over the condenser in expectation of the necessity for making frequent and rapid repairs. This condenser has, however, now been in service nearly a year, and so far has given no sign of corrosion. This is due to its superior internal design and partly, of course, to its wood lining of heavy thickness.

This condenser handles the exhaust from a 5000-kw. Curtiss turbine and holds a high vacuum with a remarkably small variation of temperature between the hot well and the entering exhaust steam.

The present steam consumption of the Curtis turbine is about 19 lb. per kilowatt-hour, whereas the former consumption when, during condenser breakdowns it was run noncondensing (for which it was not designed), was about 35 lb. per kilowatt-hour. The Beyer condenser is therefore to be credited with making a saving of 40 tons of steam per hour when run at full load, or over 400 tons per 10-hour day.

Translated into terms of coal consumption with 1 lb. of coal producing 4.2 lb. of steam, the coal saving equivalent of 400 tons of steam is about 95 tons of fuel daily, or the equivalent of about 10 men's mine production.

While it is manifestly not conservative to say that every mine should install the equipment described above, enough has been said to show the possibilities latent in its use.

As stated at the beginning of this article, the mine-labor shortage in the anthracite district is its "bugaboo." The situation is bad, but in the light of the foregoing it seems reasonable to suppose that some improvement can be made by companies that have not already installed modern machinery equipment.

When coal is burned carbon dioxide and water are the final products of complete combustion. The extent to which they are dissociated depends upon the temperature in the furnace and determines the limit of completeness of combustion.

Determination of Latitude and the Meridian

By A. C. CALLEN
Mining Engineering Department, West Virginia University, Morgantown, W. Va.

WHEN a compass mounted on a Jacob's staff was the sole instrument used by surveyors the solar attachment, invented and patented by William A Burt, in 1836, was a satisfactory means for determining the true meridian. It was recognized that the accuracy of the work was greatly increased by using the solar attachment in place of the needle. With the increasing use of the transit as the engineer's instrument it was only natural that the solar attachment should be transferred to it, in an improved and more accurate form.

Engineers are coming to realize, however, that it is difficult to keep the solar attachment in accurate adjustment, that it is an expensive "extra" and means just so much additional weight to carry. If every engineer realized that his transit is sufficient equipment for determining a meridian, doing it more accurately than by means of a solar attachment, it is probable that the use of the latter instrument would soon be obsolete.

With an instrument in good adjustment and by a little practice accurate results may be obtained. I have found that even engineering students, having no surveying experience except that gained in their elementary college work, have been able to secure results correct within about a minute of arc, after they have had a few hours' practice.

The method used is that of direct observation of the sun, which requires that a piece of colored or smoked glass be used over the eyepiece. Instrument makers supply a colored-glass eyepiece that screws on or is used instead of the regular cap. On many prismatic eyepieces there is a colored glass that swings over the opening when solar observations are to be made. If preferred, the image of the cross-hairs and the sun may be thrown on a sheet of paper or the back of a field notebook. Some engineers like this method, but I have not found it as satisfactory as the colored-glass method.

Observation for Latitude—Set up the transit at any convenient point, some time before the sun has reached his maximum altitude—that is to say, some time before true noon. Follow, with the cross-hairs, the upper or the lower edge or limb of the sun until it ceases to rise. The vertical circle will then give the greatest altitude of the observed limb of the sun. This angle is easily obtained, for the sun seems to move horizontally for a few minutes when it has reached its greatest height, and the cross-hair can be accurately set to the limb.

Observation for Determining the True Meridian—These observations should be made between 8 and 10 a.m. or 2 and 4 p.m., if possible. If made earlier than 8 a.m. or later than 4 p.m., the correction for refraction will be large and possibly inaccurate; if made later than about 10 a.m. or before 2 p.m., the sun's change in altitude is so slow that an error of 1 minute in reading the vertical circle will produce a comparatively large error in the result. Proceed as follows:

Set up the transit at one end or at any convenient point of the line whose bearing is to be determined. Having the plates clamped at zero, sight to the other end or to another point of the line and clamp the spindle or lower motion. Then, releasing the upper motion, sight the sun, bringing it, say into the upper left-hand quadrant of the cross-hairs. The sun will appear to be moving rapidly across the field; but, by using both hands to manipulate the slow-motion screws on the vertical and horizontal circles, the cross-hairs can be kept tangent to the sun, as illustrated in Fig. 1 (*a*). Record the readings of the horizontal and vertical circles and time of taking the observation. Now, quickly plunge the telescope, reverse the instrument and repeat the observation, placing the sun in the diagonally opposite quadrant as shown in Fig. 1 (*b*) and record the readings and time as before.

It is evident that the average of the readings thus obtained will give the altitude of the sun's *center* above the horizon, and the horizontal angle between the sun's center and the line at the average time of observation. The double set of observations taken not only tends to eliminate errors in the adjustment of the instrument, but brings the observations to the sun's center. The reason for making the cross-hairs tangent to the sun is that it is very difficult to place the sun in the exact center of the field of the telescope, and much greater accuracy can be secured by observing the sun in opposite quadrants and averaging the results, as explained.

In making latitude observations, also, it is possible to make double readings if the transitman is quick. Then, if the upper limb of the sun is made tangent to the horizontal cross-hair, as shown in Fig. 1 (*c*), for the first reading, and likewise the lower limb, for the second reading, as in Fig. 1 (*d*), no correction will be needed to bring the readings to the sun's center. Unless this is done, however, the semi-diameter of the sun, which is nearly 16 min. of arc (varying from about 15′ 45″ to 16′ 17″), will have to be substracted from the observed reading when observing the upper limb and added when observing the lower limb.

Owing to the refraction of the sun's rays in passing through the atmosphere, a correction for refraction must always be subtracted from the observed altitude of the sun's center before further computations are made. The amount of this correction depends on the altitude of the sun and may be obtained from the following table.

TABLE SHOWING MEAN REFRACTION CORRECTIONS TO BE SUBTRACTED FROM OBSERVED ALTITUDE IN DIRECT SOLAR OBSERVATIONS

Observed Altitude	Correction for Refraction	Observed Altitude	Correction for Refraction
10°	5′ 19″	20°	2′ 39″
11°	4′ 51″	25°	2′ 04″
12°	4′ 27″	30°	1′ 41″
13°	4′ 07″	35°	1′ 23″
14°	3′ 49″	40°	1′ 09″
15°	3′ 34″	45°	0′ 58″
16°	3′ 20″	50°	0′ 49″
17°	3′ 08″	60°	0′ 34″
18°	2′ 57″	70°	0′ 21″
19°	2′ 48″	80°	0′ 10″

Ascertaining the Sun's Declination—In calculating latitude and meridian from solar observations it is necessary to know the declination of the sun at the time

of observation. This cannot be obtained by measurement with the transit, but must be taken from the Nautical Almanac, or the Solar Ephemeris, which is published each year by practically every manufacturer of surveying instruments and can be obtained from them free of charge. The Ephemeris gives the declination of the sun for each day in the year, at Greenwich (England) noon.

In order to calculate the corresponding declination for any other time or place, it is not necessary to know

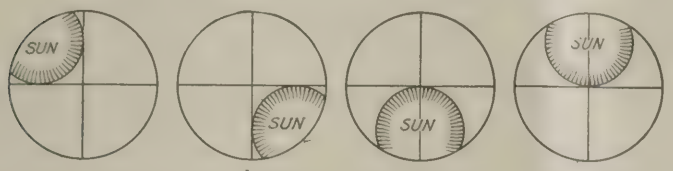

FIG. 1. APPEARANCE IN TELESCOPE WHEN OBSERVING SUN'S DISK

the longitude of the place of observation, as some assume, but only the longitude of the meridan for which the observer's watch is set. "Eastern time" is the standard time of the 75th meridian west of Greenwich; "Central time," of the 90th meridian; "Mountain time," of the 105th meridian; and "Pacific time," of the 120 meridian.

Since 15 deg. of longitude corresponds to one hour of time, it is evident that Eastern time is 5 hours behind Greenwich time, as the sun appears to move from east to west. In like manner, Central time is 6 hours, Mountain time 7 hours and Pacific time 8 hours slower than Greenwich time. To find the Greenwich time corresponding to standard time at New York, Chicago, Denver or San Francisco, it is necessary therefore to add 5, 6, 7 or 8 hours to standard time, in those localities, as indicated by the observer's watch.

Suppose, for example, it is desired to find the declination of the sun at 10 a.m. at Pittsburgh (Eastern time), May 30, 1918. This is equivalent to 3 p.m., Greenwich time. The Ephemeris gives the sun's declination, at Greenwich true noon, May 30, this year, as N. 21° 41′ 28″ and shows that this is changing at the rate of 22.8 sec. of arc each hour. For 3 p.m. therefore, since the sun's declination is increasing from Dec. 22 to June 22, the declination will be N. 21° 41′ 28″ plus three times 22.8″, or N. 21° 42′ 36″, which is the declination at Pittsburgh (or New York, Philadelphia, Bluefield, or any point having Eastern time), at 10 a.m. May 30, 1918. In like manner the declination for any other time or place may be calculated. Or, if desired, the chart devised by J. T. Beard and published in *Coal Age*, Apr. 20, p. 733, may be used instead of the method given above.

Calculation of Latitude—Having determined the altitude of the sun's center at true noon, as already described, and having obtained the declination of the sun for the time and place of observation, as well as the proper correction for refraction from the table previously given, the latitude is found by the following formula:

Lattitude = 90° — (observed altitude of sun — correction for refraction ± declination of sun)

In *north latitudes* the sign of the last term is positive if the declination is south, but negative if it is north. In *south latitudes*, the sign is positive if the declination is north, and negative if it is south.

Example—Observation taken at noon (Eastern time) at Morgantown, W. Va., May 30, 1918:

Solution—

Observed altitude of lower limb	71° 50′	
Add the semi-diameter of the sun	16′	
Altitude of sun's center	72° 06′	
Subtract correction for refraction (Table)		21″
Corrected altitude of sun's center	72° 05′	39″
Declination (Ephemeris), Greenwich noon,	21° 41′	28″ N.
Noon, Morgantown, equals 5 p.m. Greenwich.		
Add correction 5 (22.8″)		1′ 54″
Subtract declination at time of observation	21° 43′	22″ N.
	50° 22′	17″

Latitude = 90° — 50° 22′ 17″ = 39° 37′ 43″

Calculation of the True Meridian—The following formula gives the azimuth of the sun at the moment of observation.

$$Cos\ A = \pm \frac{sin\ d}{cos\ h \times cos\ l} \pm tan\ h \times tan\ l$$

A = Azimuth of the sun at time of observation;
d = Declination of sun at time of observation;
h = Altitude of sun's center corrected for refraction (Table);
l = Latitude of place of observation.

In this formula, the sign of the first term is positive if the declination is north, but negative if it is south. The sign of the second term is positive if the latitude is south, but negative if it is north. The value of cos A, as found by the formula, will generally be negative,

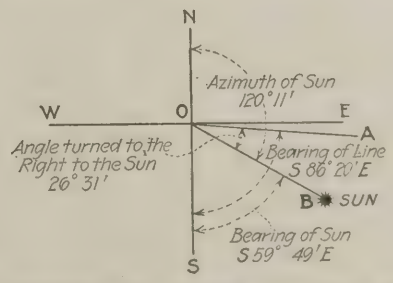

FIG. 2. DETERMINING TRUE BEARING OF SURVEY LINE BY OBSERVATION OF SUN

though it may be positive. However, the trigonometric rules for this sign will always determine in which quadrant the angle A lies.

Inasmuch as many engineers are somewhat rusty on the fine points of trigonometry it may be well to state the following rule: If cos A is negative, the bearing of the sun denoted by the angle A is southeast when the observation was made in the morning, in north latitudes; but southwest if made in the afternoon. If, however, cos A is positive, the bearing of the sun is northeast when the observation is made in the morning, in north latitudes; but northwest if made in the afternoon.

Example—Let it be required to determine the true bearing of the line OA, in Fig. 2, from the following notes obtained by direct observation of the sun, Apr. 13, 1918, in latitude N. 41° 54′, longitude, 90° W.:

Quadrant	Angle AOB	Vertical angle	Time
Upper left,	26° 20′	40° 15′	9.43 a.m.
Lower right,	26° 42′	41° 45′	9.47 a.m.
Average (sun's center),	26° 31′	41° 00′	9.45 a.m.

Solution—

9.45 a.m. (90° *W*) = 3.45 p.m. Greenwich.

Declination, noon Greenwich, Apr. 13, 1918,	N.	8″ 51′ 02″
Add Correction, 3¾(54.6″)		3′ 25″
Corrected declination (*d*)	N.	8° 54′ 27″
Altitude sun's center,		41°
Subtract correction for refraction, (see table)		0.1′ 07″
Corrected altitude (*h*)		40° 58′ 53″
Latitude (*l*)	N.	41° 54′

Substituting these values, sin d = 0.1548; cos h = 0.75492; cos l = 0.74431; tan h = 0.86872; tan l = 0.89725 in the formula previously given, we find

$$\text{Cos } A = \frac{0.15480}{0.75492 \times 0.74431} - 0.86872 \times 0.89725$$

$$= +0.27561 - 0.77946 = -0.50385$$

The azimuth of the sun is therefore 120° 11′; or, according to the rule previously given, the bearing of the sun is S 59° 49′ E (180° — 120° 11′ = 59° 49′). Since the angle AOB, turned to the right to the sun from the line was 26° 31′, the true bearing of the line OA is S 86° 20′ E (59° 49′ + 26° 31′ = 86° 20′).

It may be noted that there are several instruments on the market, which are either straight or circular slide rules, made for the purpose of solving a formula for the azimuth of the sun. Their use does not appreciably lessen the labor of making a meridian determination, however, as the readings must be made with the transit and the declination and corrected altitude of the sun determined as just described. In my opinion, it is questionable whether it pays to purchase one of these contrivances when a five-place table of trigonometric functions will be more accurate and less costly.

When the clocks have been set to accord with the "Daylight Saving Law" it is important to remember that one hour should be subtracted from clock time to give the standard time used in computing the sun's declination.

The velocity of chemical reaction increases with rise in temperature. At ordinary atmospheric temperatures the oxidation of carbon monoxide and hydrogen proceeds so slowly that the velocity of reaction can not be measured. At high temperatures and with thorough mixing, oxidation takes place rapidly; that is, the gases burn.—*Bureau of Mines Bulletin No. 135.*

Where the Coal We Produce Is Consumed

The United States Geological Survey is quoted by George S. Rice, in his "Review of the Coal Situation of the World," read before the American Institute of Mining Engineers at the February meeting, and he has furnished us the following table which gives some further details for the benefit of those who have not seen the original computation:

CONSUMPTION OF BITUMINOUS COAL IN THE UNITED STATES, 1915

Purpose	Tonnage Short Tons	Per Cent.
Industrial steam uses	143,765,500	33.0
Railroads	122,000,000	28.0
Domestic purposes and small steam trade	71,336,489	16.0
Beehive and byproduct coke	61,832,898	13.6
Exports	18,773,782	4.0
Mines for steam and power	9,798,681	2.0
Bunker coal (ocean and Great Lakes)	10,707,507	2.3
Manufacture of coal gas	4,563,579	1.0
Miscellaneous	714,073	0.1
Totals	443,492,509	100.0

Minecdotes

500 Volts Versus 250 Volts

There has always been a rather strong tendency among engineers to use 500 volts for a mine-locomotive haulage system in preference to 250 volts, owing to the great saving in copper and the better voltage regulation that is obtained.

A few years ago a well-known engineer with one of the large electrical manufacturers was emphatic in his advocacy of 500 volts for mine-haulage systems, feeling that there was practically no more personal danger than when 250 volts were used. This engineer was exceeding prolific in the use of a certain class of the English language more commonly known as "French." In fact, he could put the average oldtime Irish labor boss to shame in a short space of time.

During a visit of a number of engineers to a mine located in the vicinity of Johnstown, Penn., the party was inspecting the haulage system inside of the mine when the engineer mentioned above passed from one side of the track to the other. His hat being off, his bald head brushed the 500-volt trolley wire; and the ground being wet, the result can be imagined. Some exceedingly rapid action then took place, the mud flying about in all directions.

The engineer landed up against the rib, glared at the trolley wire and then cut loose. He kept going for about 15 min. without repeating himself, and the miners working in the vicinity, although hardened to nearly any kind of language, just stood around with their mouths open in amazement. Later, at the superintendent's office, when the incident was all but forgotten, a delegation of miners came out of the mine and asked the superintendent if that man who knew how to talk was gone; and if not, they would like to hear him talk some more.

Needless to say, after the foregoing experience the engineer strongly advised that 250 volts was the maximum which should be used for mine haulage under any conditions.

Marcus Screen at Plants of the Carnegie Coal Co., Pennsylvania

BY RICHARD G. MILLER*
Chicago, Ill.

IT HAS been said that the most vital question before the American people today is the coal problem. Authoritative opinion asserts that the labor and transportation questions are the principal difficulties in the mining and distribution of coal. Over 100,000 coal miners are subject to the draft, so that the industry is facing a serious labor problem. Moreover, according to estimates, 100,000,000 more tons of coal will be required during 1918 than during 1917, for carrying on our war program and continuing our national life. Under the existing circumstances these 100,000,000 more tons of coal likely will not be forthcoming, so it remains for us to do what we can in order that we come as near to meeting the requirements as possible. It will therefore be necessary to make the greatest use of efficient machinery and labor-saving devices in our attempt at this goal.

Transportation or the lack thereof received a good share of the blame for past and present conditions, and no doubt the car-shortage problem has to a greater or lesser degree affected the shortage of labor. Furthermore, the shipping of dirty coal not only compels the railroads to haul useless material, but it decreases the efficiency of industrial plants as well as the railroads, by reason of the increased percentage of refuse in the coal. This decrease in efficiency is not only due to the low heat value of the dirty coal, but also to the additional expense necessary for handling the larger quantity of ash.

There is a difference of opinion among people with regard to who is most responsible for this larger percentage of refuse in the coal. Some think it is due to the defects in the producing organization, while others think that the miners are more to blame. However, the blame in many instances, no doubt, should be shared by both.

Methods of Removing Impurities

In some localities mining conditions are such that it is not advisable or practical to attempt to eliminate all the removable refuse at the face; while there are many instances where coal, devoid of rock or slate, could readily be delivered to the tipple or screening equipment. However, operators have an opportunity at this time to manifest their patriotism and provide themselves, where necessary, with adequate means for removing as large a percentage as possible of the slate, rock, bony coal or sulphur balls from the good coal at the tipple before loading into the railroad cars.

Of course, each particular mine has its own set of conditions to consider in determining just what methods should be provided for producing a coal with a minimum percentage of ash. All the measures adopted should be made fully adequate to the task to be imposed upon them irrespective of the enormous demand for coal, or the price paid for it; the former has run riot, while the latter has been regulated by the Government.

Many operators have had the foresight to include in the design of their plants special machinery and equipment for improving the quality of their product. Those now in a position to market, and also those who can modify their facilities for marketing a better prepared product, should receive recognition from the Fuel Administration by the granting of an additional price per ton to such operators. The justification for this premium, whatever the merits of a particular case may warrant, will be due to the additional investment required for the special means and the additional labor also required for obtaining the "extraordinarily clean coal."

Problems in Coal Cleaning

In deciding upon the type of equipment, many features of existing plants govern the procedure, due to the fact that the impurities in the various coals exist in different forms, and also that in one size they are different from that in another. For example, it may happen that the lump coal at a particular plant carries with it most of the removable refuse either as rock, slate, bone or sulphur balls, while the nut or egg coal at another plant might carry these impurities. It therefore may be necessary in one case to use one method of elimination and in the other case some other method.

If, however, these impurities occur in the finer sizes of coal, a more complex method of improving the quality, such as washing, might be necessary. The coarser sizes at most mines are the grades which could be more easily improved by simpler methods. If a large part of the impurities in these sizes could be picked out by the addition, to existing plants, of a moderate amount of simple picking machinery (especially the Marcus combined screen and picking table), then the necessary additional investment and labor required for manning the improvements would be small in proportion to the improvement in the product.

Coal companies in various localities have adopted picking facilities of one or another type. It is notable at this time to observe that especially in the western Pennsylvania field, such companies as the Pittsburgh Coal Co., the Pennsylvania Coal and Coke Corporation and the Carnegie Coal Co. have adopted the combined screen and picking table as a means of meeting the present situation in the most economical way. This is true both as to the necessary investment of capital and the labor required for producing a coal with the minimum amount of ash without going to the necessity of washing. It is desirable to avoid washing except where the coal is used for coking purposes, in which

*Contracting engineer of the Roberts & Schaefer Co., engineers and contractors, McCormick Building, Chicago, Illinois.

case low ash and also low sulphur are imperative. These and other coal companies who have adopted the Marcus screen are in a position to ship "extraordinarily clean coal" and thereby receive an additional price per ton by obtaining permission from the Fuel Administration.

The organizations mentioned above have, all told, 17 of their properties equipped as stated, but the Carnegie Coal Co., with six operating properties near Pittsburgh, is in a class by itself, having six tipples provided with seven of the Marcus horizontal combined screens and picking tables.

One of these installations is a new plant, while the rest are old plants worked over, the old plants having previously been equipped with the old style gravity bar screens and weigh baskets.

New Carnegie Plant

The new plant of the Carnegie Coal Co. is at the Louise mine, illustrated by Fig. 1A and shown diagrammatically in Fig. 1. This plant is unique for the reason that the Marcus screen *A* is designed so that a car of coal is dumped into the dump chute, fed by means of the feeder *B* so that the preceding car of coal remains separate on the screen from the car following and the removable refuse is picked out by pickers after the fine or slack coal passes to the bottom deck.

When the picking operation is completed the coal enters the weigh hopper *G*, the pickings never being weighed, so that the miner in no case is paid for the removable dirt in the coal. Moreover, the speed of the coal on the screen is such, and the arrangement of the screenhouse and the position of the weighman is such, that if a car of coal comes along which contains an extra large quantity of dirt, then the equipment is stopped for an instant—long enough to completely remove all of these visible impurities.

The miners knowing this are therefore more careful not to waste their time filling a car with dirt, because it would be useless to them. It might be said in passing that this design was more or less experimental at the time it was developed, but with only a few minor changes in details after erection it was made to work most satisfactorily.

If Fig. 1 is carefully followed, it will be noticed that the lump coal is delivered by means of the shaker loading boom *I* to the center track, while the nut coal is loaded by the chute *N* to the outside track and the slack coal by the chute *S* to the inside track.

Figs. 2, 3, 4, 5 and 6 are diagrams of the McDonald, Atlasburg, Primrose, Armide and Oakdale plants respectively, all of which illustrate installations at existing tipples. All these tipples, with the exception of the Atlasburg plant, are single Marcus screen installations; the Atlasburg plant is a shaft mine and provided with duplicate equipment.

In Fig. 2 the coal is dumped into a weigh hopper, the weighing and operating mechanism of which is suspended overhead. The reciprocating feeder *B* feeds the coal onto the horizontal screen *A*, after which it passes successively over the slack perforated screen, the blank picking space and then the nut perforated screen.

By this procedure, the fine coal is first removed from the coarser sizes so that the removable impurities can be more easily seen and removed because of the decreased quantity of coal on the combined screen and picking table. These finer sizes pass to the lower deck, and in the case of the slack coal is immediately loaded into railroad cars on the slack track by the chute *S;* the nut is loaded into railroad cars on the center track by the chute *N* and the lump over the shaker loading boom *I* is loaded on the outside track. The pickers remove the rock, slate, bony coal or sulphur balls, throwing them into the refuse trough *F*, which being rigidly attached to the screen conveys them forward, delivering them by means of the chute *K* to a refuse car for the purposes of disposal.

This arrangement of combined screening and picking machinery gives the most perfect screening and loading facilities as well as a most efficient means for picking. Obviously this design lends itself readily to installation in existing structures, which is quite in its favor, in addition to the greatly improved preparation that is thus made possible.

Coming to a discussion of the Atlasburg plant, which is illustrated diagrammatically in Fig. 3, we have an example of a duplicate horizontal equipment as applied to a shaft tipple. The original plant was of steel construction and with slight modifications in it the equipment readily adapted itself, giving all the advantages of modern screening and picking. The weigh basket *G* was changed to a double bottom discharge type so that it became necessary to furnish a new dump chute designed with doors for the disposition of mine rock by way of the rock chute *O*. The car on the rock trestle carries this to a rock pile not shown in the diagram. From the weigh basket *G* the coal from either or both self-dumping cages is delivered to either or both of the reciprocating feeders *B* and onto the Marcus screens *A*. The operation of these screens is the same as previously described, including the feature of the fixed refuse trough *F* for delivering pickings to the pickings chute *K*.

FIG. 1A. VIEW OF TIPPLE SHOWN IN FIG. 1

One point of difference, however, is that this is a four-track equipment, which lends itself to loading lump coal from one Marcus screen over the shaker loading boom *I;* picked run-of-mine or picked egg and lump combined can be loaded on the second track, or *vice versa;* at the same time slack coal and nut coal can be loaded from either or both screens to the railroad

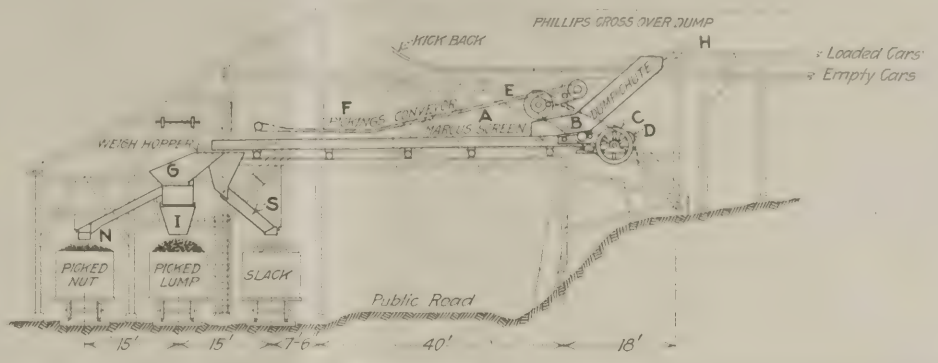

FIG. 1

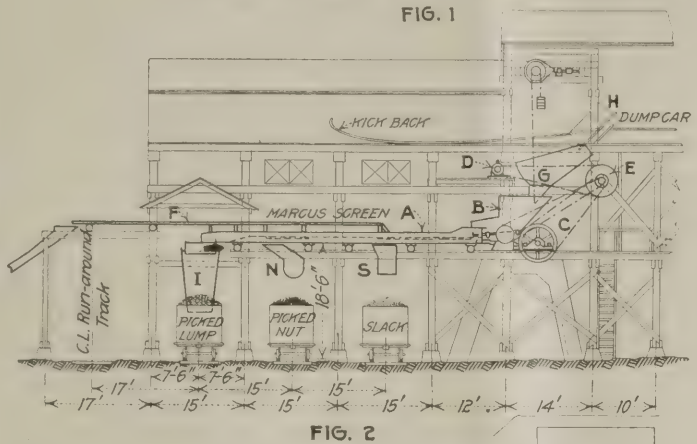

FIG. 2

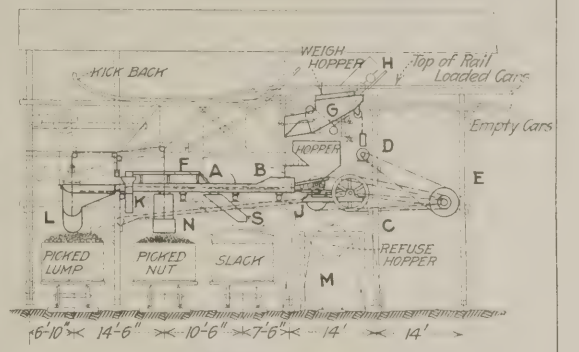

FIG. 4

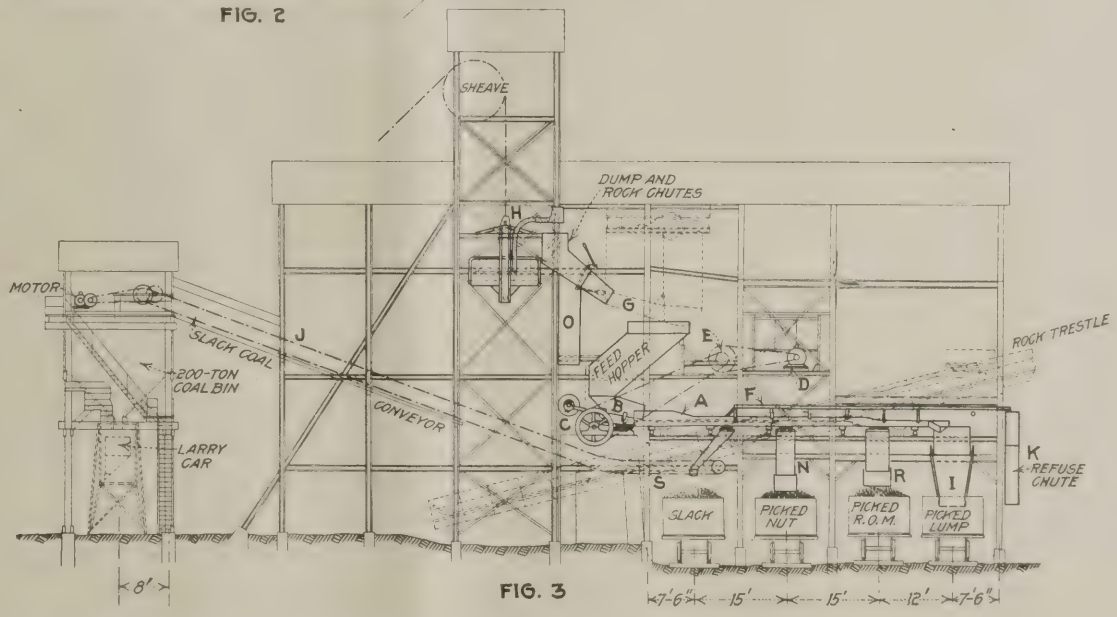

FIG. 3

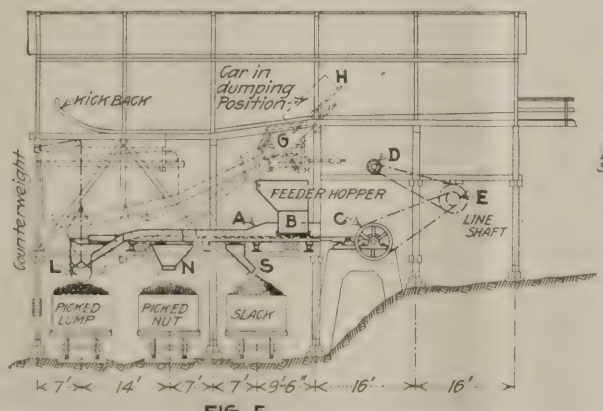

FIG. 5

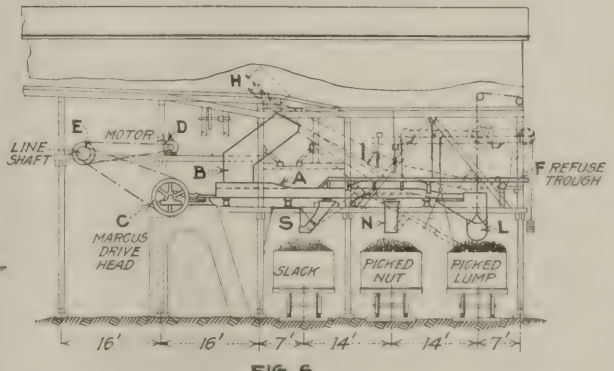

FIG. 6

FIGS. 1 TO 6. PLANTS OF CARNEGIE COAL CO. IN WHICH MARCUS SCREEN HAS BEEN INSTALLED

cars on the slack track by way of the chute *S;* or railroad cars can be loaded on the nut track by way of the chute *N*. This point in the design adds to the flexibility of operation in the case of emergency, which is a valuable asset at any coal-preparation plant. In connection with this installation, also, the slack conveyor *J* can receive slack coal from either or both screens and deliver to the 200-ton coal bin on the left for loading larries to charge the coke ovens. The installing of this equipment at the Atlasburg plant was done without interfering with the operation of the mine or hoisting of coal.

The Primrose plant, as illustrated in Fig. 4; the Armide plant, Fig. 5; as well as the Oakdale plant, Fig. 6, are similar equipments of the same type of machinery which was installed where the old gravity bar screens and weigh baskets were undisturbed. These are shown in light dotted lines, whereas the new equipment is shown bolder. Each is a three-track arrangement making lump, nut and slack coal. Loading booms in these three cases were not required for the lump coal, and the plant illustrated in Fig. 5 is not equipped for refuse disposal as the nature of the coal and preparation required did not demand it.

At Primrose the standard rigidly connected refuse trough *F* is shorter than usual, delivering sideways to the chute *K* into the pickings conveyor *J*. This arrangement facilitates operation by taking the pickings to the rear for disposal; having this fixed refuse trough *F* makes it convenient for depositing the pickings as they are removed from the coal.

The disposal of refuse at the Oakdale plant is done in a manner similar to that described for the McDonald plant, illustrated in Fig. 2. For feeding the screens at Armide and Oakdale, and to facilitate installing them without disturbing the existing bar-screen equipment, the feeders in these two cases were placed at right angles to the screen, which will be noticed by observing the diagrams.

The principal thing to bear in mind in considering these installations, which are intended to facilitate removing the refuse as well as to improve screening, is that in each and every case the fine coal is screened from the run-of-mine coal before any picking is done. This leaves the coarser sizes by themselves and in lesser quantities, so that pickers can see the bone, slate, rock or sulphur balls and therefore can better remove them.

Another big advantage, and this is that after picking is accomplished the finer sizes, screened out at the start, travel to the front end of the screen by closing the slide gates on the bottom deck; here they combine with the picked coarser sizes, giving a picked run-of-mine product mixed as uniformly as it was before the separation at the start of the process.

It is obvious that coals with a large percentage of slack, therefore, are the ones most conveniently picked by this method. For the general run of cases it is a more efficient method as regards operation, because usually about one-third of the run-of-mine coal is black which passes to the lower deck of the Marcus, relieving the picking operation therefore of one-third of the volume of coal. Furthermore, after the coal on the screen passes the nut perforations the egg and lump in lesser volume are more easily picked; after the egg coal passes through the egg screen, the lump coal alone remains and can be picked just before it reaches the lump chute or loading boom.

Every engineer interested in the preparation of coal in all probability has at one time or another felt the need of a combination arrangement whereby coal could be simultaneously cleaned and screened, and it therefore seems strange that until recently a device of this sort had not been developed.

It has been approximately four years since the Marcus combined screen and picking table was introduced into the United States. Previously to that time it had been thoroughly tried out in foreign countries, including among others England, Germany, Algiers, Borneo, Japan, South America, Mexico and Canada.

At the present time in the United States there are more than 100 of this class of coal-preparation plants in operation and building. It is interesting to note that the application of this device has been very general, applying itself to all classes of bituminous coal, including the harder, medium and softer grades as well as the lignites and semi-bituminous coals. These plants are in operation from Wyoming to Pennsylvania and from North Dakota to Alabama.

The installations described and illustrated, and as put in operation for the Carnegie Coal Co., were all designed and built by the Roberts & Schaefer Co., of Chicago, Illinois.

Some New Ideas in Coal Storage

A recent article by Prof. George Knox, published in the Journal of the Monmouthshire Colliery Officials Association, while it advises that no slack coal or mixed small coals be stacked to a height of over 13 ft., urges that coal for coking purposes should not be piled more than 4 ft. deep, for slight heating renders the coal unfit for coking purposes.

Professor Knox adds that inferior coal should not be mixed with the better varieties. "Rashings" or other friable bituminous shale bands should be removed as far as possible. Coal should never be stacked behind wooden structures, on moist vegetable soils or on ground covered by coarse vegetation. Mr. Knox does not say why the vegetation is objectionable, but it may be because it has in itself a great tendency to heat. It probably does not have any direct, or chemical, effect on the coal.

Where "Byproductless" Ovens Waste Coal

The following tabulation has been made from the enumerations of ovens in the various states of the union, as made by *The Coal Catalog* :

State	Beehive Ovens	Rectangular Ovens	Total Ovens	Per Cent.
1. Pennsylvania	45,523	3,185	48,708	57.41
2. West Virginia	16,511	.....	16,511	19.46
3. Alabama	6,111	.....	6,111	7.20
4. Virginia	5,082	.....	5,082	5.99
5. Colorado	2,994	.....	2,994	3.53
6. Tennessee	2,003	.....	2,003	2.36
7. Kentucky	875	150	1,025	1.21
8. Utah	874	.....	874	1.03
9. New Mexico	817	.....	817	0.96
10. Washington	232	.....	232	0.28
11. Oklahoma	200	.....	200	0.24
12. Ohio	178	.....	178	0.21
13. Illinois	104	.....	104	0.12
	81,504	3,335	84,839	100.00

The number will probably decline from this time onward, as the byproduct oven will doubtless drive out the "byproductless" oven in a few short years.

Coal Production and Lubrication

BY REGINALD TRAUTSCHOLD
New York City

SYNOPSIS—*The greatest problem in coal production, outside of railroad car supply, is transportation from the face to the tipple. Heretofore a cheap grade of fluid, black oil, has been used in large quantities. Much of this has dripped or run out of the bearings without performing the service for which it was used. More modern semi-grease compounds have in service given much better results.*

A RECORD production of bituminous coal, an anthracite output close to normal, and the prospect that the car shortage will soon be relieved go far toward removing some of the pessimistic forebodings of a few weeks ago. Although these conditions seem to have engendered a feeling of optimism for the time being, the growing scarcity of labor is, nevertheless, viewed with much disquietude.

This mixture of emotions is further enhanced by the discouraging reports from the anthracite fields. In certain mines, despite the fact that the number of persons engaged in production of coal has increased, there has been a marked diminution in output. This decrease in labor productiveness is explained by poor attendance. Absences on the part of the workers ran from 8 to 15 per cent.

A production of coal decreasing more rapidly than the available labor supply would be a calamity to the country, yet the report from the anthracite field would appear to indicate such a possibility. To guard against this, and to secure a material increase in production with the growing scarcity of labor is one of the country's vital problems, to realize which every ounce of energy and precaution must be expended. Coal production must be increased in spite of the labor situation and this can only be accomplished through material improvements in present-day conditions.

Should Use Every Available Mechanical Aid

Every effective mechanical aid must be pressed into service. Unnecessary absences must be prevented, the efficiency of the workers must be increased and this can be realized by placing more and more dependence upon mechanical assistance and by decreasing the manual efforts required of the miners and their helpers.

The more general use of mining machines, mine-car loaders and the numerous other mechanical aids of proved value now on the market will all materially assist in securing coal with a minimum amount of labor. Production in a mine employing adequate mechanical aids resolves itself, to a considerable extent, into a problem of expediting and facilitating the movement of mine cars from the face of the coal to the tipple.

The gradual withdrawal of the time-honored mine mule to the more urgent work on the battlefield and behind the lines—work for which "Maud" appears to be particularly qualified, and for which she must be spared—necessitates the installation of mechanical systems of mine-car haulage. The passing of the mule tends to cut down the number of persons required, since by locomotive longer trains can be handled. In this way the changed conditions tend to adjust production to reduced labor supply. It is not enough, however, that production be maintained in spite of a decrease in the working force; it must be materially increased.

Speed of passage through the haulageways and facility in moving the cars are thus essential if the gains in output which can be secured at the face are to be fully realized and effective advantage taken of the speed with which the cars can be dumped at the shaft bottom or on the tipple. The problem is primarily one of improvement in rolling stock, and any modification, practice or installation which will lighten the labor of handling the mine cars must be adopted. Obviously, the first step in this direction is a complete overhauling of all mining equipment, the equalization of grades and, of chief importance, the securing of proper lubrication.

Importance of Lubrication in Coal Mining

How important the question of lubrication is to a coal mine may be judged from the quantities of lubricants annually consumed. In one anthracite mine with an annual output of somewhat less than 4 million tons, close to 50 tons of grease were required and some 53,000 gal. or more of liquid lubricants. Starting from the power house, proper lubrication is required for every piece of moving equipment—engines, pumps, etc.—but the major amount of lubricant is employed for the mine cars. At this particular mine, which is typical of the great majority of such operations throughout the country, 60 per cent. of the total lubricant consumed was car oil. Thus, about 0.0136 gal. of car oil was used for every ton of coal mined.

Obviously there is here an important opportunity for economy in the use of lubricant and an accompanying saving in the attention which must be given to mine cars. No such quantity of lubricant would be required if it effectively discharged the service for which it was supplied. Not only can a lubricant be ineffective, but a considerable amount of time may be consumed in the frequent refillings that such lavish use necessitates. Quite aside from the questionable economy of such lubrication is the consideration of the labor required in feeding the oil to the journal boxes or bearings.

Heavy railway cars require replenishment of lubricant only every 1000 to 3000 miles, while mine cars are considered to be giving good service when they average 50 miles per oiling. Emphasizing still further the inefficiency of ordinary mine-car lubrication is the fact that from one-quarter to one-half the power generated at the colliery is used for mine haulage.

The car oil in use at the mine under consideration, as in many others throughout the country, was "black oil." This lubricant is employed chiefly because it is cheap. Much of it drips from the bearings without performing any useful work. Tests have shown that when such oil is used for mine-car lubrication, from 50 to 90 per cent. of it is wasted. Any such inefficient lubrication would

not be tolerated outside of a mine, and the use of this oil is here accepted solely because it has always been considered the suitable lubricant. This is an example of the blind acceptance of dangerous traditions.

Not only is from two to ten times as much "black strap" as is effective in combating journal friction required when using such oil for lubrication of mine cars, but the dripping oil is apt to fall on the track and cause a lack of grip of the driving wheels on the rails. The floors of the haulageways become oil-soaked, making footing insecure and materially increasing the already high fire risk of a coal mine. The use of any lubricants that are easily volatilized should be prohibited, particularly when other far more stable and effective lubricants are easily obtainable.

A mine-car lubricant in order to be considered satisfactory today must be one of high lubricating value, unusual tenacity—a tenacity equal to that of a high-grade grease in order to guard against drippage and to prevent its being squeezed out of the bearing under load; impervious to acid and alkali solutions or fumes with which it may come in contact and of lasting qualities in order to economize in labor for lubricating. These exacting requirements, important as they are at any time, are infinitely more so at present if the coal demands of the country are to be met. The use of such a lubricant (which is now obtainable) would cut down the frequency of lubricating periods to one each three to six months, reduce the tractive force required to start and move mine cars and greatly improve operation.

Proper Lubrication a Matter of Test

General lubricant requirements for bettering the operating conditions have been enumerated before taking up the more specific requirements imposed by the type of mine-car bearing or journal construction, in order to emphasize the necessity of exercising great care in the selection of lubricants. The construction of the bearing should be given proper consideration in selecting the most effective lubricant. A lubricant best suited for a roller-bearing construction, for instance, does not prove to be the best suited for the lubrication of a plain-bearing wheel.

The importance of bearing construction on lubrication was appreciated even when an oil was recommended which could be wasted without entailing a heavy monetary loss.

The bearing and journal constructions employed for mine cars affect primarily the amount of tractive force required for their movement. The effective operation of the existing mine rolling stock is now of more importance than the immediate installation of more efficient running gears. All available mine cars must be put into service, operated to the best possible advantage, and the lubrication of any type of bearing construction not allowed to jeopardize the rate of handling coal by cars equipped with other types of running gears. That is, the evils incident to the use of lubricants readily affected by changes in temperature, whether these be climatic or originate in the bearings, must be avoided.

For mine cars, a lubricant is required that will not drip, spatter or climb, one with the tenacity of a high-grade grease, but without its failing of having to melt before it can function. These exacting requirements are possessed by certain products now on the market, the products of specialists who have made an intimate study of the lubrication requirements of mine cars and the conditions under which effective service has to be discharged.

In many instances the trucks of the mine car may pass through water, necessitating an insoluble lubricant. Frequently this water is strongly charged with acid or alkali, under which conditions the lubricant must be impervious to the action of such solutions. Gases and fumes of a penetrating and corroding nature are also sometimes encountered, and the lubricant must resist the attack of such mediums and be able to protect the bearing surfaces from them. It is imperative, also, that the lubricant possess lasting qualities, for the lubrication of mine cars should be unnecessary more than three or four times a year.

Any mine-car lubricant that fails to function effectively under any of these conditions possesses a failing which may cause an interruption to the continuous and rapid movement of cars necessitated by the intensive operation of the mine. The requisite lubricant must be one which will not fail in its service under the most trying conditions. It should be, then, a special product of a lubricant manufacturer with wide experience in the specialty field. Among such products are the Slo-flo lubricants made by the Swan & Finch Co., of New York.

The lubrication of plain car wheels or journal boxes calls for a lubricant of the consistency of a medium grade of cup grease when reduced to lubricating consistency. The grade of the above lubricant best suited for this service is classified as No. 28. This is also admirably suited for use with solid roller bearings, since its consistency is sufficiently free flowing as not to interfere with the effective functioning of the rollers and at the same time is of sufficient body to withstand the heavy "squeegee" action of the rollers on the bearing surfaces of the shaft and cage.

For securing the best efficiency from the distinctive hollow roller construction of the Hyatt bearing, a slightly lighter lubricant is advisable. The hollow rollers act as reservoirs for the storage of lubricant and the helical flexible construction—alternate rollers wound in opposite directions—causes the lubricant to be distributed continuously over the bearing surface, first in one direction and then in the other. This wash back and forth assures even and continual lubrication of bearing surfaces, permitting the use of a more free flowing lubricant than could be advisably employed for bearings with the ordinary solid type of roller. The grade developed for use with the Hyatt construction of bearing is No. 27.

The use of either of the two grades of lubricant specifically mentioned, or that of any other particular brand or grade, cannot as a matter of course assure an increase in coal production. As aids toward such an end, however, they are extremely valuable. Coal can be cut with mining machines to meet almost any demand, despite the growing labor shortage; almost any capacity can be handled on the tipples, prepared for the market and, it is hoped, dispatched to distributing points and industrial centers. The vital consideration now, therefore, is to expedite the movement of the coal from the face to the tipple. And in this connection proper lubrication plays an exceedingly important part.

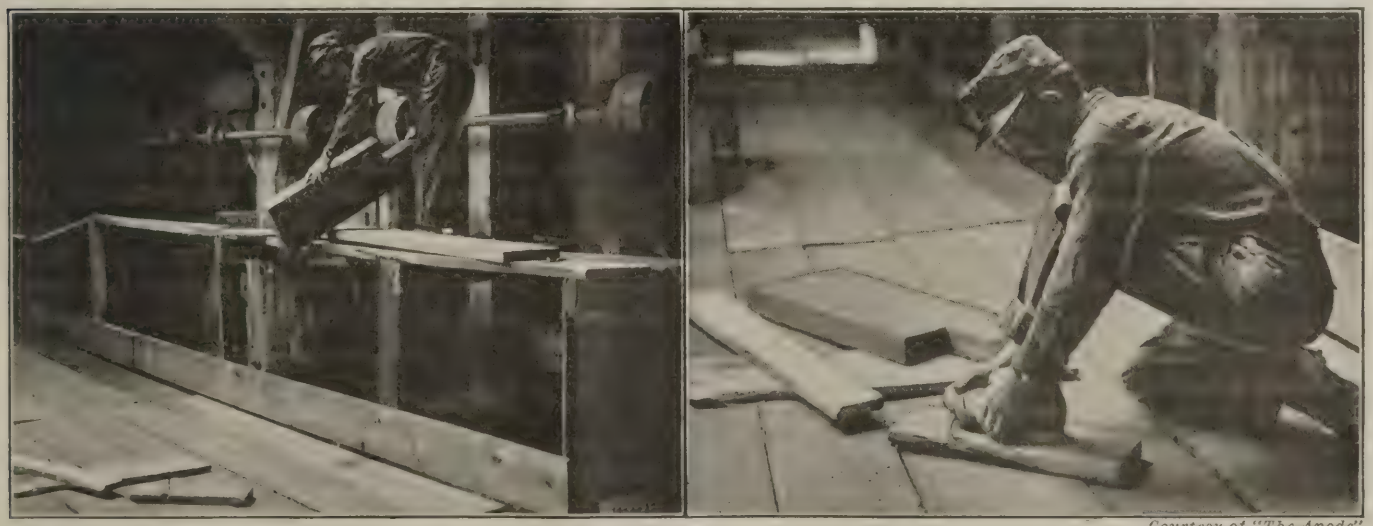
DEPARTMENT OF HUMAN INTEREST

Using Moving Pictures for Education

The Bureau of Commercial Economics, Washington, D. C., has the germ of a great idea, an idea which it is impossible to put immediately into complete execution, but one which is to be welcomed even in its initiatory stages. It is to prepare a series of moving pictures for the education of the public and the individuals in industry and to give through the eye the impressions which the tongue fails to convey because of its restricted powers of expression and because of the barriers set up by the many different languages of the diverse peoples who have thronged within our gates.

The bureau has already a coal film. It is not to all appearance well adapted to the teaching of mining, but it does, at least, show the importance of the industry in the present juncture. That is a message well worthy of the telling. The mine worker needs to realize the fact that his industry is basic and necessary to the proper conduct of the war.

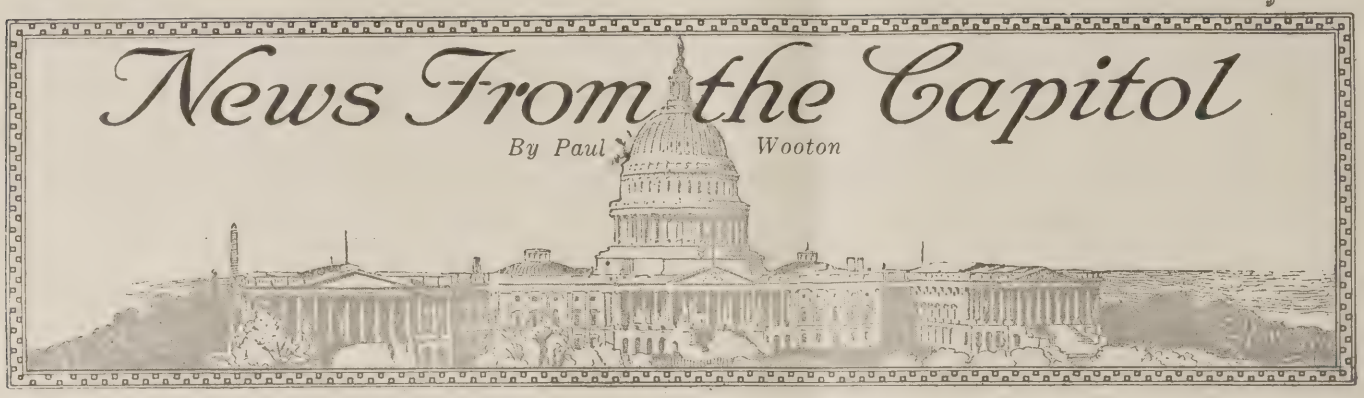
Under the head of "mining" in the coal film is shown prospecting, boring, mine construction, operation of breakers, the loading of railroad cars, the shipment of coal, distribution and storage. Similarly the "oil refining" film illustrates the boring, casing, piping and tanking of oil, and the "refinery" film shows the separated products, the barreling of oil, pipe-line transportation and storage.



Other pictures give the mine worker an idea of the vast number and variety of the products made from coal, including, of course, in this such explosives as picric acid and trinitrotoluol. Thus they give him a realization of the dependence of the country on his active labors and in this manner stimulate his patriotism and urge him to larger service.

The Bureau of Commercial Economics is prepared to loan to any coal company any of its films. It does this through the various coöperating universities situatedthe all over the country, which act as service stations to any coal organization requiring the use of them. No charge is made for the service except for transportation charges from and to the distributing center.

The bureau requires that the films be shown on a standard motion-picture projector and manipulated by an experienced operator. It expects a report of the films shown and the number of persons who see them, and it further stipulates that no admission fees be charged when the film is shown. A booklet has been prepared by the bureau giving a partial list of the available subjects. The institution is maintained by voluntary subscriptions and annuities on which it depends for an extension of its activities.



May Injured Employees Select Doctor?

The question of a coal company's liability for the doctor bill of an employee who refuses to avail himself of the services of the company's physicians and engages his own is involved in two writs of certiorari which have been obtained at Carlinville, Ill., by the Superior Coal Co. One is against Samuel O'Neil and the Industrial Commission of Illinois and the other is against John O'Berta. O'Neil was injured in the company's mine Oct. 16, 1917. Although the company had five physicians at Gillespie and two at Benld, and the employees had been so notified, O'Neil consulted others and their bill of $44.70 was presented to the arbitrators of the Industrial Commission and the company was notified to pay it. The company in the writ raises the objection that allowance of the bill is against the provisions of the compensation act. The circumstances in the O'Berta case are the same. His doctor and hospital bill is $97. He also filed a claim for $156 for wages lost and afterward raised this to $1731. The company claims all these charges are against the provisions of the compensation act.

WHEN WILL WE LEARN THE EVER-PRESENT DANGERS OF THE UPTURNED NAIL AND OF THE THIN WELL-WORN SHOE SOLE?

Unforeseen Coal Demands Drain Supply

Rapid increases in the demands being made on this country's coal supply are viewed with growing alarm at the Fuel Administration. Not a week passes that does not see a new or an additional requirement which had not been included in former estimates. A recent call for coal for use in France and another to take care of an English obligation in Chile are the latest types of demand of which no previous calculation had been made. It is this continual drain on our supplies which is spurring both the production and the conservation division to their maximum effort.

Some see hope in the fact that both France and England have been able to increase their production materially after the first two years of war, during which production declined considerably. While coal production in the United States increased 10 per cent. during our first year of war, and promises to increase another 10 per cent. this second year, it may be possible to make even a larger proportionate increase next year. Since it was possible for England and France to attain important increases in production after sufficient time had elapsed to permit of more thorough organization of the industry, it is reasoned that we, too, will find ways and means of mining coal in greater volume.

High Production in Many Districts

Production records are being made in many coal districts. Alabama, during the week ended July 13, produced 412,478 tons. The previous high record for the district was 379,737 tons. The Big Sandy and the Elkhorn districts of Kentucky report the production of 157,996 tons during the same week. The best previous performance was 137,993 tons. Central Pennsylvania exceeded its previous high record of 1,175,883 tons by 150,000 tons. The Uniontown district of Pennsylvania exceeded the best previous record by 8000 tons.

Dealers Fail to File Weekly Reports

Railroad station agents are to divert coal consigned to dealers who have not filed weekly reports with the Fuel Administration. July 1 there were 750 dealers in New England who were delinquent in their reports. They were given until July 10 to get them in. All but 70 complied. Of the number to whom all shipments were denied, 37 are located in Maine, 20 in Massachusetts, 5 in Rhode Island, 3 in Connecticut, 3 in New Hampshire and 2 in Vermont.

Ohio Distributor's License Revoked

John W. Moore, of Columbus, Ohio, has been deprived of his fuel distributor's license for the violation of the regulations with regard to the distribution of coal. The Elk Coal Co., of which he is president, has been ordered to refund several thousand dollars which it had collected in commissions on transactions which had been carried on under the license issued personally to its president.

Lightless Nights Again in Effect

Thousands of tons of coal will be saved, it is estimated, by the new lightless night order. For four days of the week—Monday, Tuesday, Wednesday and Thursday—the New England states, New York, Pennsylvania, New Jersey, Delaware, Maryland and the District of Columbia have been ordered to discontinue the use of all illuminating signs and lights used for the external ornamentation of any building. In all the other states lightless nights are to be observed on Monday and Tuesday of each week. Roof gardens, outdoor restaurants and outdoor moving picture theaters are excepted in all sections.

All public lighting is to be reduced to that necessary for safety. Certain standards will be arrived at so that the local officials of the Fuel Administration will be able to secure the same degree of compliance throughout the country.

The Bureau of Standards estimates that 500,000 tons of coal are used in generating the electricity required for advertising purposes. Advertising lighting in New York City is responsible for the consumption of 16,000 tons per year.

To Increase Anthracite Supply to New York

During April, May and June New York City received slightly more than its allotment of anthracite coal. Movement into New York is to be increased as much as possible during the next three months, so as to cut down the amount which it will be necessary to handle after the coming of cold weather.

New England Hard Coal Shipments

During April, May and June 3,250,000 tons of anthracite moved into New England. The total which must be moved during the coal year is 10,331,000 tons. It is the aim of the Fuel Administration to move two-thirds of the total before the winter season begins.

Limits Use of Smokeless Coal

Smokeless coal passing into consumption by way of the Lake docks must be used solely for the manufacture of illuminating gas, byproduct coke or coal briquettes. If a specific case should arise where it is imperative to use low-volatile coal for another purpose, a special permit may be issued by the district representative of the Fuel Administration.

To Receive Preference in Anthracite

Communities which would experience the greatest inconvenience in changing from anthracite to bituminous coal are to be given preference in allotting the supplies which have been portioned out. This policy of the Fuel Administration became known when fuel administrators in Michigan, Ohio, Indiana and Illinois were given instructions as to how each state's proportion of anthracite is to be allocated.

To Cut Off Fuel Supply from Consumers Who Fail to Answer Questionnaires

It is feared at the Fuel Administration that it is going to be necessary to take drastic steps to secure responses from the questionnaires recently sent to consumers. Experience at the Fuel Administration has demonstrated that the most practicable way of securing compliance from the dilatory ones is to cut off coal supply. Since a great deal depends on the conclusions which must be drawn from the information asked of the consumers, there will be no hesitation in diverting their coal supply until the data requested are furnished.

Many Applications for Opening New Mines

So great has become the demand for a more lenient policy in the matter of granting permits for the opening of new coal mines, that a survey of the situation is in progress. More than 500 applications for permission to open new mines have been received by the Fuel Administration in the last six months. Only a few permits have been granted. Most of the requests have received unfavorable action on account of the fact that labor and transportation conditions in the district where it is proposed to open the mines are such that new operations would be likely to retard present production. It is recognized, however, that the development of new properties should not be retarded too long, and the matter is to be the subject of conferences in the near future between Samuel A. Taylor, the engineer adviser of Doctor Garfield, and interested operators.

Brief Washington Notes

An important part of the funds obtained by the Bethlehem Steel Corporation from the War Finance Corporation is to be expended for coke ovens at the Sparrows Point plant.

The Senate has passed Senator Gronna's bill authorizing the Bureau of Mines to spend $150,000 in the investigation of lignite coals to determine the practicability of their utilization.

Anthracite Shipments for June

The shipments of anthracite for June, as reported to the Anthracite Bureau of Information in Philadelphia, amounted to 6,867,669 long tons, as compared with 6,887,256 tons in May, and with 7,049,037 tons in June, 1917. These figures show that so far as the total tonnage is concerned, the output is being well maintained, shipments for June being only 19,587 tons less than in May of this year, and 181,368 tons less than in June, 1917, in both of which months the calendar provided 26 working days as against 25 days in June.

The average daily shipments were 271,117 tons in June, 1917; 264,894 tons in May, and 274,707 tons in June of this year. The effect of the labor scarcity is, however, being increasingly felt, as shown in the comparisons of the shipments of domestic sizes, practically all of which are from fresh-mined coal.

In June, 1917, the shipments of domestic sizes, including pea coal, amounted to 4,781,969 tons; in June of this year they fell to 4,498,976 tons, a decrease of 282,993 tons, or about 100,000 tons more than the total decrease last month as compared with a year ago.

In the first three months of the present coal year, beginning April 1, the total shipments have amounted to 20,123,298 tons as compared with 19,558,861 tons for the corresponding period in 1917, indicating an increase of 564,437 tons. The shipments of domestic sizes, however, show a loss of 95,908 tons from 13,375,797 tons in 1917 to 13,279,889 tons in 1918.

The shipments of steam coal, a goodly proportion of which is recovered from culm banks, increased 660,345 tons or over 10 per cent. Distributed by carrier companies the shipments during June were as follows:

	June, 1918	June, 1917	Coal Year, 1918	Coal Year, 1917
P. & R. Ry.	1,345,079	1,341,370	3,935,469	3,686,981

Wagon Miners Combine

Between 300 and 400 owners of wagon mines met at Pittsburgh, June 27, and formed the Wagon Mine Owners' Association, the following officers being elected: H. S. Morrow, Frankstown road, Penn township, president; A. Audley Pierce, McKeesport, vice president; R. B. MacPherson, West End; Frederick W. Scott, Fair Haven; D. B. Sober, Tarentum; James L. Steele, Crafton, and F. J. Riddle, Turtle Creek, vice presidents; A. W. Mendel, North Side, secretary, and Hyatt M. Cribbs, Verona, treasurer.

The association so far includes few wagon-mine owners outside of Allegheny County, but the members are anticipating an extension of the list so as to embrace all the wagon-mine owners in Greene, Fayette, Westmoreland and Beaver Counties. A community coal pile will be formed at Pittsburgh. All surplus coal will be stored on this pile, cash being paid for the coal on its delivery. Emphasis is to be placed on the mining of clean coal. An increased rate, above $2.35 per ton, is to be sought by the wagon-mine owners. D. W. Kuhn, the fuel administrator of Pittsburgh, delivered an address.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Already the work of the production department of the Fuel Administration, backed by the loyalty of the operators, union leaders and mine workers, is attaining results. We used to hope for an output of 12,000,000 tons of bituminous coal a week, and until the week ending June 8 we did not once get it. The output for the week ending July 13 was 10 per cent. larger than that figure. The mines produced 13,243,000 tons; this is equivalent to 688,636,000 tons a year if the speed can in the future be maintained and if it had been maintained during the months past.

Unfortunately, the railroads are not likely to furnish so adequate a service when moving crops or struggling with winter conditions. We must therefore look jealously at the output of the present moment. It is time for effort. Unfortunately, it has to be provident effort—the kind of effort which takes the highest kind of ideals. We can all work when the need immediately presses. A boy will gather wood when the fire is needed to warm up the room, but he is not so keen to cut and stack it for the winter's need.

The anthracite difficulties with regard to conscription do not seem to right themselves. Nothing but official discouragement of the enlistment of miners will keep them from entering the service. The boards will have to supply the protest themselves if they are going to prevent men from leaving the mines for the army and navy. Such half-hearted action in the matter as has been taken by the Provost Marshal's department will not cure the situation. The recent victories will make it even harder than in the past to hold the men at the coal face.

DANGEROUS TO MAKE INDUSTRIAL DISTINCTIONS

Crowder has given the draft boards the right to use their judgment. They are not under orders to put men into deferred classes, but they can do so if they desire, and we are led to understand that no protest to that action will come from headquarters. That is something, but still hardly enough to produce the desired results. One can understand the attitude of the Provost Marshal's department. It would rather treat every industry alike. There are many war industries, and it is hard to distinguish between them.

If the anthracite region is exempted, the bituminous industry will expect exemption on the ground that it is even more a war industry. This is true enough. The only reason why the anthracite region asks for exemption is because, while its product is essential in peace and in war alike, it is suffering more than almost any other by reason of labor shortage. It certainly is far shorter of men than the bituminous region.

There is some hope that some national recognition will be given to miners which will impress on them the importance of their work in the war. This will not be given to all miners; only those who do their part will receive the recognition which will be in the form of a service badge. By some it is expected that the award will be distributed by special committees at the mines guided by the record at the weigh scale.

The Hudson Coal Co.'s Greenwood colliery is located at Minooka, in that region of Bolshevism and labor trouble which lies south of Scranton. Between 800 and 900 men and boys who work at this colliery are on strike to increase the pay of some of the men. The mines closed down tight on July 16. It seems needless to say that no strike was necessary, as a Conciliation Board exists to settle all difficulties by arbitration. A strike is not only an unpatriotic but an extremely expensive way of righting a wrong and extremely wicked way of wronging a right.

James Gleason, organizer for the union, and a member of the executive board, declares the company is justified by its contract and adds that the mine workers are trying to get the Hudson standard raised to the level of that paid by other companies nearby. The regular meeting of the local will not occur till July 30, and the men are not disposed to call a meeting before that date. Meanwhile, at last reports, the strike was continuing.

There are not wanted evidences of the reason for the large tonnage to which we directed attention earlier in this review. Spangler, in Cambria County, central Pennsylvania, near neighbor to Barnsboro, Hastings and Patton, planned to hold a Firemen's Convention and Carnival. The four towns mentioned are all miners' towns, with little else than mining to support them. Had the convention been celebrated the whole section would have been laid idle. Men would have been drawn into Spangler by street car and railroad from far and near, for that region is fairly netted with railroads and trolley lines. James B. Neale, Director of Production, however, urged that the carefully laid plans be abandoned and by telegram came back the response that there would be no Firemen's Convention and Carnival. The affair would have started Aug. 11 and lasted through the week. The Fuel Administration does not approve of festivities of this kind so long as the need for steady work is as marked as at the present.

In northern West Virginia, so long nonunion, unionization is rapidly proceeding without opposition from the Consolidation Coal Co. and other large companies, if not with their active coöperation. There are, as usual, some men who do not desire to join, and some 12 organizers from various parts of the country are busy day and night arguing the benefits of unionization to the convinced and skeptical alike. Mother Jones, who for a while was sent to this region, went to Washington following a celebration at Clarksburg, July 4. The coal operators understand that she will not return to the Fairmont section.

ASKING DEPARTMENT OF LABOR FOR MINERS

Vance Randolph, examiner in charge of the United States Employment Service Free Bureau, recently located at Clarksburg, has orders for 500 men from the Consolidation Coal Co., including miners, machine men, machine helpers, coke pullers, and coke forkers. At a meeting of the Clarksburg Coal Club operators in that immediate vicinity gave him an order for 460 men and yet there were several other operations to be heard from.

In the Kanawha region the speeches made by Major Sandford, of the British army, during the last two weeks have had a potent effect in bringing the miners of that district to a realization of the needs of the war. The soldiers of the pick are now doing their duty as earnestly as the soldiers in khaki.

Miners at a certain mine in Raleigh County, in the Winding Gulf region, went to the manager of the company and informed him that they were ready to forego an eight-hour day and work nine hours, or as long as was necessary.

At Panama, Ill., the United Mine Workers' Union is suffering from the effects of too much prosperity. A scandal has developed in connection with the administration of the union's finances. The recording secretary is missing from Panama and the State Auditor of the organization is making an examination of the books to ascertain how the union managed last year to spend $59,000 for expenses. The auditors are said to have found numerous irregularities in the issuance and payment of warrants and checks; the amounts on both having been "raised," according to reports. Many checks not regularly signed by the officers of the union are said to have been cashed.

Operators Will Pay for Funerals

On July 8 a resolution was introduced by James Matthews, of Shamokin, Penn., president of District No. 9, United Mine Workers, at a session of the Anthracite Conciliation Board. Its provisions are best set forth in the actual wording of the resolution, because any attempt to rewrite it subjects one to the temptation of adding to its provisions those additional clauses that it was evidently the intention to have inferred or incorporated.

However, it may be permissible to say that while the purpose of avoiding funeral lay-offs is clearly stated, there is nothing in the agreement to make it clear whether a company would be justified in refusing to pay the funeral expenses where all the men decided not to work on the day of the funeral. Nor is the period limited to the time of the war, though the war is noted as cause for the provision.

There is also nothing to show whether the employed members of the family are only permitted to attend the funeral as members of the mine delegation or are not referred to at all in the resolution, their right to presence as members of the family being conceded. These matters should undoubtedly have been covered in the contract. Apparently the mine foreman is only an advisory member of the committee, for the grievance committee of the colliery is sure always to outvote him. Labor contracts should be written carefully. Their meaning should be absolutely above question. Unfortunately, both in the anthracite and bituminous coal regions ambiguity in contracts is quite frequent. The shortness of the contractual term saves the contracting parties from more frequent disputes. As it is, however, there are more than are necessary. This contract reads:

"The Board of Conciliation believes that as a war measure, at a time when public necessity requires a maximum production of coal, there should be no cessation of the operation of mines and collieries on account of the death of an employee caused by an accident or on account of funerals, and to the end that all collieries remain in full operation in such circumstances and in consideration thereof, it be directed that the operators pay to the nearest heir of the deceased employee whose death has been caused by accident the sum of $150, and in addition thereto directs that the grievance committee and mine foreman elect six representatives of the respective colliery to attend the funeral, it being understood that the six men be selected that will least cripple the operation on that day and that the wages of these six representatives be paid by the operator."

This resolution doubtless was the outcome of an understanding in which not only the members of the board, but the operators also, participated. It was accepted by the board as soon as submitted and it will be regarded in all probability as a part of the contractual obligations of the anthracite region so long as the war lasts. It has been hailed as a example of coöperation between employer and employee, but really it is a breach of contract accepted by the employer under pressure from the employee. The companies yielded easily and gracefully to their employees feeling that they could not let their rights avail anything when the national interests were at stake. The mine workers will do well to remember this and see if they "can go the operators one better" when some little matter that they can correct holds up the progress of the work.

Wages and Practices of Wagon Mines

The bonuses paid by the smaller mines working the less-desirable coal beds have been the cause of much of the high-price coal in central Pennsylvania. Some concerns instead of paying the scale rate of $1.10 are paying $1.60 a ton. Even at that figure they cannot get the help they want. It takes more than that to dislodge the workmen from the regular mines where work is conducted under better principles with better equipment and better conditions. And when the men are so dislodged it only aids the inefficient mine to the disadvantage of the efficient operation and of the nation at large.

The wagon mines have been extremely slow in loading railroad cars. Some will order a car placed and then be 10 days or two weeks filling it with coal. There are about 20 concerns in the central Pennsylvania district that will be brought to book under the new fuel regulations which have been promulgated against paying wages above the union schedule. The board of investigations held its first meeting July 5.

The following members have been appointed by the United States Fuel Administrator: John C. Forsyth, Harry Boulton and Charles O'Neill, all of Clearfield, and B. M. Clark, of Punxsutawney. The Central Pennsylvania Coal Operators' Association has appointed as its representatives: Judge A. O. Smith, of Clearfield, chairman; J. R. Caseley, of Dubois; T. V. Gould, of Brisbin; Earl Hewitt, of Blairsville, and M. J. Bracken, of Gallitzin. The alternates of the association's membership are George Nicholson, of Barnesboro; J. A. Bucher, of Beaverdale; C. B. Maxwell, of Morrisdale; H. B. Douglas, of Clearfield, and W. R. Wilburn, of Philipsburg.

Prohibition and Labor in West Virginia

The idleness following Independence Day at the West Virginia mines is acting in favor of prohibitionary measures, and yet, strange to say, it also acts against any such action.

West Virginia is a prohibition state, but it has neighbors that have not signed the pledge—Pennsylvania, Ohio, Maryland and Kentucky. In some sections the dry can migrate to the happy lands with bars, notably in the Panhandle, the Thacker and Kenova districts, the Elk Garden and Upper Potomac regions and the mines north of Fairmont.

But there are regions which are, or should be, as dry as the heart of Arabia—the New River and Kanawha regions, where much carfare must be spent and a long holiday taken if refreshment is needed. Yet the New River region says that Independence Day was over-well celebrated and did not end on July 5.

If, therefore, West Virginia speaks with an uncertain voice it is because different parts have a different experience. The Panhandle, which vainly tries to push a dry finger into the prevailing wetness of Ohio on the one side and Pennsylvania on the other, is convinced that July 4 proved to the hilt that national prohibition is needed.

The West Virginia Panhandle Coal Operators' Association, of which Johnson C. McKinley is president, addressed telegrams last week to Senator Howard Sutherland and Dr. H. A. Garfield, United States Fuel Administrator, expressing approval of Senator Sutherland's support of national prohibition, and recommending to Dr. Garfield the establishment of a five-mile dry zone around coal mines, in case the present movement to establish national prohibition fails.

In the telegram to Dr. Garfield, Mr. McKinley said: "We heartily concur in your belief that increased production of bituminous coal is absolutely essential to the winning of the war and urge your support of the effort now being made to abolish the sale of intoxicating liquor so long as the war lasts. Industrial conditions in West Virginia have improved materially since prohibition became effective in this state, but the coal mines of this section operate at a disadvantage because of the saloons in the border counties of Ohio. In case of failure of the present movement to establish prohibition, we would respectfully urge that a five-mile dry zone be established around coal mines as was advocated by the National Coal Association in October last, but total prohibition for the entire country we believe very desirable at this time."

As already said, New River cannot call on the hospitality of neighboring states and consequently should have observed Independence Day for 12 hours only and then retired decently for a hard day's work on the day following. But it is said that the New River people lost all their enthusiasm for putting out coal during the festivities of the Fourth. At one or two operations, where after Independence Day the operators threatened to put the penalty clause of the contract into effect if the mine workers failed to go to work, the men threatened to go on a strike. In fact, it is said that there are a few leaders in the union, few indeed but enough nevertheless to make trouble, who declare to the Washington authorities that they are loyal, but at the same time discourage the men from doing their best.

Attempt to Guarantee Justice Fails

The lamentable failure of a jury to find a verdict against the persons who recently hanged the inoffensive Robert Paul Prager at Collinsville, Ill., who was murdered simply because he had fallen under the suspicion of the mine workers, was the chief argument presented by proponents of a bill to grant to the state of Arkansas the right to change the venue of trials for men accused of mob and criminal violence. The bill proposed a change of the constitution of the state.

A few years ago, July 17, 1914, Arkansas was the scene of some extremely unfortunate riots. Men were killed and four tipples were burned at Prairie Creek (see *Coal Age*, Vol. 6, pp. 145, 191 and 270). A few days later another tipple was dynamited at Huntingdon. For this reason Arkansas should realize the need for changes of venue such as will make it easy to deal with general breaches of the peace for which conviction cannot be obtained in a local court owing to the general prevalence of sympathy with the law breakers. Yet despite this fact the change in the constitution, which would have given the law officers of the state this much needed power, was denied by a vote of 52 to 47.

Some Enter Mines to Avoid Draft

Some men in Illinois have been entering the mines to avoid the draft. The underground workings look quite attractive to men of draft age, for they hope that draft immunity will be conceded to those engaged in the production of coal. But the men who enter the mines to evade the draft have little or no intention of working steadily.

Frank Farrington, president of the United Mine Workers in Illinois, has made a statement indorsing Fuel Administrator Garfield's recommendation to President Wilson that draft of miners for the army be stopped. The coal industry of Illinois is, he says, already suffering from a shortage of labor due to the drafting of mine workers. "The draft," he adds, "is taking from the mines the young and agile men who must be depended on to keep the coal moving out of the mines. Tripriders, motormen and mule drivers, who are mostly young men, are fast being withdrawn from the mines by the draft, and a serious shortage will result from any further drafts."

In Canada Draftees Must Work or Fight

Coal mining is classified in Canada as a work of national necessity, and coal miners are treated as a special class in the enforcement of the Military Service Act of Canada. The course to be pursued in regard to the application of conscription to the miners has been a matter of serious consideration to the tribunals of British Columbia and other western mining provinces that are charged with power to grant exemptions, temporary and permanent. The attitude assumed by Judge Thompson of British Columbia recently may be taken as indicative of the generally accepted policy in this respect. In the Crowsnest Pass coal district he was confronted recently with a blanket appeal for exemption for 36 men—the appeal having the backing of the United Mine Workers of America. It was based on the contention that the appellants were engaged in a work of national importance. After hearing all the evidence as to the actual time being worked by each man, the amount of coal produced and the individual earnings, he allowed 31 applications for a limited period, renewal being conditional on the maintenance of an average production of coal by the men whose application for temporary exemption was approved.

In giving judgment Judge Thompson established the following rules:

"1—In cases where I grant exemption it shall be conditional upon the appellant being continuously employed in his occupation, either that in which he is now engaged or some other occupation in the mine. Any person ceasing to work for more than 24 hr. will be deemed to be not continuously employed, unless he can show some just cause or reason for his nonemployment. This prohibition does not apply to recognized holidays and the holding of funerals.

"2—A lay-off of 24 hr. without just cause or reason being shown shall not occur more than once a month. In case of illness a certificate signed by some medical practitioner must be produced within 48 hr., and if demanded by the military or civil authorities produced and filed in the office of the chief of provincial police at Fernie, B. C.

"3—In the event of a strike or cessation of work by workmen other than exempted men whereby the latter are prevented from working, exemption shall cease, subject, however, to the provisions of rules 9 and 10." (These are certain rules laid down in the agreement subsisting between employer and employee in this district.) Judge Thompson here observes: "This may seem a harsh ruling but it must be remembered that this appeal has been made by the United Mine Workers of America and it will be the duty of the officials of the brotherhood to see that no such strikes or cessations of work occur."

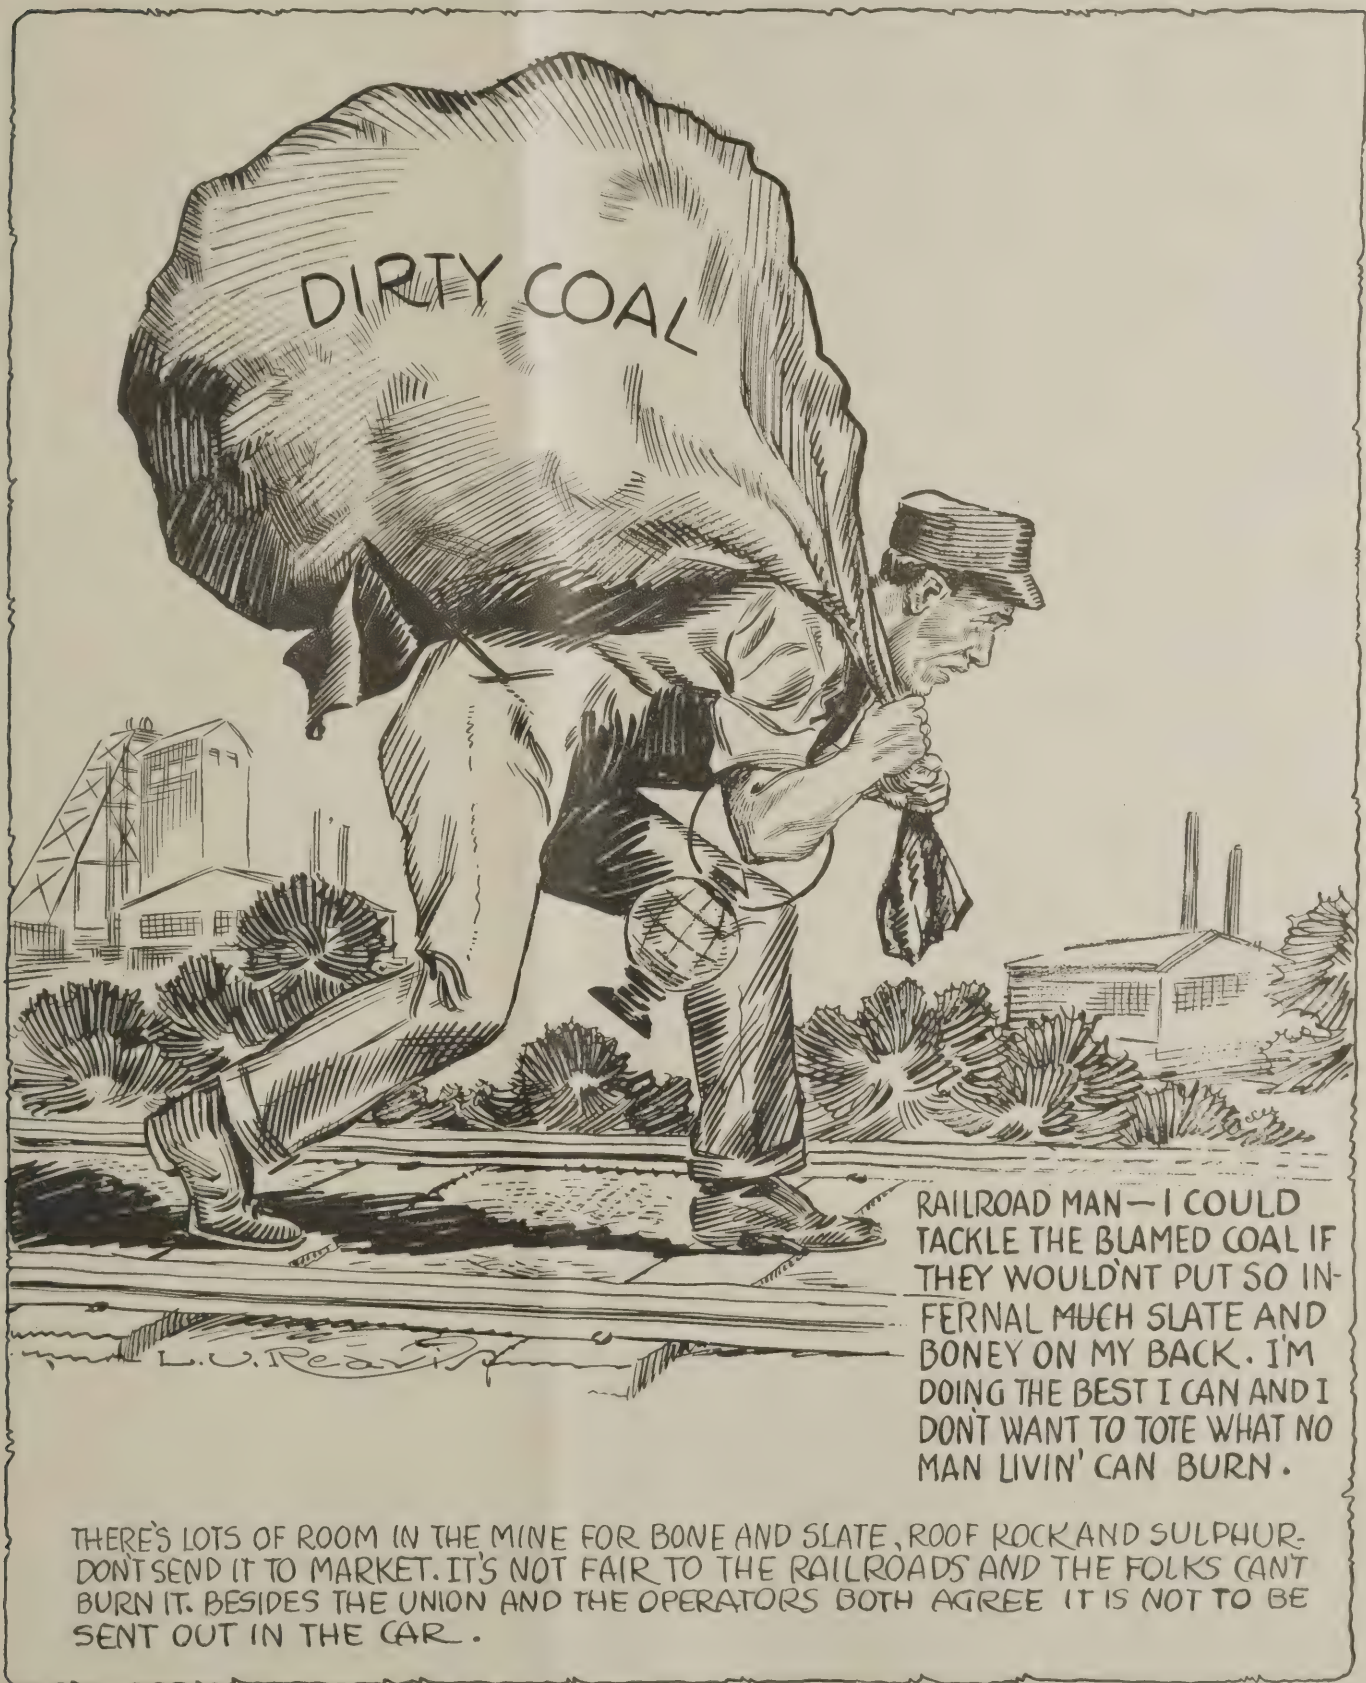
"4—No exempted man shall occupy an official position or carry on work which will necessitate his absence from work at his usual occupation in the mines. In the event of any person to whom exemption is granted desiring to change his employment from one employer to another he may do so upon application being made in writing to me and a certificate allowed by me.

"5—In the event of any dispute arising between the military authorities and any person to whom exemption is granted, or in the event of the military authorities drafting, detaining or arresting an exempted man for alleged noncompliance with these rules, or from any cause, the matter shall be brought before me speedily as possible for determination."

Putting the Slacker on Record

A record of the slackers such as is kept in parts of the anthracite region is to be made in the Connellsville field. It is not to be a complete record. It will only give the number of days of idleness, not the number of hours of working opportunity lost, but it is a good commencement. It is thought that the record now kept will serve as a basis for future choice between workers.

The material for such a record has in a degree always been available. The bushel record of the loaders was always posted for all and sundry to note and this record was in fact a better criterion of the industry of that class of worker than the record now proposed, while the day record of the day man could always be secured by a perusal of the pay rolls. But now a record is to be made for each worker and care will be taken to ascertain in every case of absenteeism whether the absence was accompanied by an acceptable excuse.



The Fayette County Fuel Administration is back of this new departure. C. E. Lenhart and R. M. Fry of the Uniontown region and J. M. Jamison, of Greensburg, members of the regional fuel committee, met at Washington with W. S. Blauvelt, coke director, and the legal advisors of the fuel administration, and decided that the plan should be adopted.

The operators will use the record, should they after the war is over have occasion to lay off men because business is bad. Those who have not been loyal to the nation during the war will be given their walking papers first.

The men themselves have entered into the spirit of the ruling. Its operation, while yet at too early a stage to permit any conclusions to be drawn, will without a doubt have an effect in stiffening the morale of the coal and coke workers.

Fuel administration officials point out that a majority of the men in the region are intensely loyal but that a slight minority of them have become restive under the abnormal wage scale. The fuel administration is working in close coöperation with the county draft boards, and the labor records kept by the fuel administration will be available to draft authorities for the enforcement of the "work or fight" ruling.

It's Hard Enough Work To Tote This Year's Coal, So Leave the Rock in the Mine

EDITORIALS

Pulverized Fuel

IN THE early days when anthracite was struggling for commercial recognition, nothing short of selected lump was accepted by the domestic consumer. He broke it up by hand for use in his stove. Today the smallest particle of combustible coming from the mine is conserved for immediate use or the probable demands of the future.

With the rapidly increasing demand for fuel and the better knowledge as to available supplies and their limitations for meeting future demands comes greater conservation of resources. Cheapening of costs of manufacture and simplifying labor problems lead to further refinements in processes, greater use of machinery and the more complete utilization of byproducts. From the foregoing, the use of pulverized fuel is a natural outcome. In some cases the application of this form of fuel seems to have passed the experimental stage; in other instances difficulties which developed have not always been overcome.

Possibly the first successful extensive commercial use of pulverized coal as fuel was in the cement industry. Here there was a pressing demand for a low-priced fuel of high efficiency, and powdered coal has proved to be almost an ideal fuel. It has come into almost universal use as a fuel for clinkering cement. It has also found wide application in many chemical and metallurgical furnaces. It has steadily advanced in a great variety of fields where requirements call for a degree of heat that may be readily controlled.

Machinery has been developed which will dry, pulverize and deliver fuel to furnaces at a reasonable cost. The advantages of powdered fuel are well known, including the utilization of practically every heat unit in coal and the use of automatic machinery which only needs supervision, adjustment and repair. With the decreasing and uncertain supply of fuel oil and natural gas, there is increasing interest in the use of byproducts of mining and manufacture. Anthracite culm, bituminous screenings and coke breeze assume a new and further importance.

The subject of pulverized fuel is most alluring, but balancing its notable successes are conspicuous failures. Its superiority and economy over successful stokers are slight if measureable. On railroad locomotives its use seems to have passed the experimental stage, and commercial applications are said to be making headway, especially in the West. This special field offers unusual attractions to the advocates of pulverized fuel, as next to labor the largest single item of cost in transportation is the fuel used in locomotive operation. Locomotives exact a toll of about one-quarter of the coal moved over railroads, which represents an expenditure of some 300 million dollars annually. Of this amount 75 to 100 millions of dollars are required to kindle, clean and maintain fires on grates at times when locomotives are non-productive. Railway demands are more exacting every year, and the use of pulverized fuel may be not only a most effective and economical means for increasing net earnings, but may also satisfy the demands of the public for a reduction in smoke, cinders and sparks.

It is a misfortune that this process has not been extended to include the furnaces of most general use, the class consuming more coal possibly than all other industrial furnaces combined. As applied to the generation of steam in externally fired boilers, the process has met difficulties which have not been generally overcome. In one special type of boiler developed to meet the special requirements of the combustion of pulverized fuel a certain measure of success has been attained. But in the main the process has not been successfully applied to existing steam plants, especially the water-tube boiler.

Among the causes of failure, inadequate combustion space seems to be prominent. The actual combustion should take place with the coal particle in suspension and in cramped space destruction of brickwork and boiler parts may result. The handling of molten ash is another serious problem. If existing plants can be readily adapted to pulverized fuel requirements, then the process would likely receive approval. If a plant must be scrapped to introduce the system, its adoption would probably be delayed some time in active power stations.

Coal Recovery Situation in Illinois

RARELY are coal mining and agriculture so closely associated as in scores of counties in Illinois, and rarely is each industry entitled to a leading place, as in this state. Nature has endowed the prairies of this state with a wonderfully rich soil on which record crops of corn and other farm products are raised. And underneath the surface is stored for use during the coming centuries billions of tons of fuel remarkable for its comparative freedom from impurities and for ideal conditions of mining.

To harmonize these two important industries so as to permit the freest development of each is a big and vital problem. The large coal interests have taken the lead in investigation of conditions affecting the situation. They have been accused as the aggressors in numerous suits for alleged damages to surface in which it was claimed that subsidence and other disturbances were due to improper methods of mining. Until recent years the operators have mined coal in many instances without much system, satisfied to leave two or three cars of coal in the mine for every car sent to the surface, provided the cost per ton would meet the fierce competition and resulting low market price for their product.

The conditions under which mining was carried on tended to give small recovery of coal, squeezes and unsatisfactory results generally. However, it was only recently that surveys have been made by operators to show just what percentage of coal was being recov-

ered. As the value of coal lands appreciated, a number of companies employed engineers to ascertain the amount of coal left in the ground. Finally, interest in this matter reached such a stage that concerted action was taken, and investigation was made of conditions of mining and percentage of extraction of coal in numerous Illinois mines under a coöperative agreement between the Engineering Experiment Station of the University of Illinois, the Illinois State Geological Survey and the United States Bureau of Mines. As an example of their findings it was learned that the recovery of coal in twelve average mines was 42 per cent.—it should have been 80 per cent. As a result of this agitation a change of mining was made in a number of instances with better recovery. In a general way, the adoption of the panel system has given the best results in Illinois up to the present time. But even with the improvements already made there is still abundant opportunity for much better recovery.

Let the Operator Get on the Job

THE mine foreman has rarely had a fair opportunity to make a good showing. Between the law (which regards him as a safety engineer and so trots him to every working face to see if it is safe) and the operator (who views him as a sort of mine manager) he never has had a moment of time. Scarcely has he arrived at the mine than a dozen persons assail him.

One man is about to go home; he has no props. Another man has his coat on and his pail in his hand; he cannot work, his place is full of water. Gennaro Baptiste is wildly gesticulating, trying to tell the boss in "pidgin" English that Tom Stuck didn't cut his place last night and that he, Gennaro, is consequently out of work.

Usually there is no night foreman. Only when the boss comes round in the morning does he learn how a quarter or a third of the night force failed to come out or, having come out, failed for one of a dozen reasons to do a night's work.

Where there is gas there are firebosses during the night turn, but they are usually too busy to correct what is amiss and frequently are not trusted to hire or direct others in the work of repair. Everything waits on the boss, and as he has been trained to regard himself as the end-all and be-all of his operation, he would not have it otherwise.

In a well-ordered mine the mine boss is merely the boss of the bosses in a mine. He is not afraid to have capable certificated men under him. He gives each a certain trick or a certain territory and holds him responsible for its steady running. If the operator had handled his foremen right, had told them the story of Carnegie wanting men who knew more than he did to run his various departments, had pointed out that a foreman was not rated by how hard he worked or how cheaply he supervised the mine, but on the general cheapness of the operation and the steady flow of coal to the tipple, there would be a very different condition.

The cost of supervision per ton may increase, the cost of roadmen and tracklayers may rise, the cost of blacksmiths and carpenters may grow larger; but if the haulage, dumping, pumping, cleaning and trimming costs decline by reason of larger output and better supervision, what matter about these smaller costs? The mine foreman is a worried man, and a worried man never yet made his employer rich.

Get in touch with your foreman. He has been longing to ask you for several changes, but has lost heart because you cut him off so inconsiderately. Look at his problems with your broader business vision. Ask yourself if a business can be run where the night work is performed by men without supervision and when the early morning finds all the loose ends of the night before to be solved in 15 or 30 minutes. Too often it must be so solved or a goodly minority of the miners get disgusted and restless and so march home.

Get on the job and see the foreman in action. If he had as many hands and heads as a Buddha, he could not perform what is expected of him. View the foreman sympathetically, not critically. Let him see that you are there to help. Stay long enough so that the foreman will not try to shelve difficulties until you are gone. You will soon see why the mine runs so badly, for it is equipped with only one mind and one pair of eyes—the mind and eyes of the mine foreman. If the foreman would only let some one else do some of the thinking and a little of the seeing, if the operator would only pay some one to do a little of both, many a roughly moving operation would run smoothly thereafter.

Cheering News from the Coal Mines

THIS is the period of the year usually marked by small demand for coal and low production. The miner goes to the farm to work, or goes a-hunting with his dogs. There are plenty of cars on all sidings and no orders. In 1916 there were mined in the second week of July perhaps one and one-half million tons of bituminous coal per day. In 1917 the pressure of the country's needs brought the production of bituminous coal in the second week of July to its maximum for the year. The output was nearly two million tons a day—33 per cent. more than in 1916.

This year the maximum is also reached in the second week of July. The tonnage is 2,207,000 tons per day—10 per cent. higher than last year. With fewer men the bituminous mines are producing a larger tonnage. Part of this can be credited to better car service, but a large amount may safely be laid to patriotism. Sentiment, much decried sentiment, is the basis of our success. In fact the moral forces of life are even more important than the mental and physical forces.

Let us be careful, however, about feeling overjoyed about our wonderful success in the industrial field. Let us not forget that while the second week of July last year was the date of our maximum output, it was also the date on which our production began to slump. From two million tons a day in the second week of July the production fell almost continuously to less than 1,700,000 a day in the week ending Aug. 17. Then the production rallied, but it hovered around 1,800,000 tons for the rest of the year, with a couple of slumps, when it fell well below that level.

This decline must not occur this year. The Railroad Administration, mine workers and the coal operators must resolutely determine to raise the record or keep it where it stands. The work of the week ending July 13 must not stand as a monument on the line of production.

DISCUSSION BY READERS

Shortage of Mine Labor

Letter No. 4—After reading the two letters on this subject published in *Coal Age*, June 29, pp. 1209 and 1210, I cannot refrain from remarking on one or two points suggested by the writers.

In the first place, I want to say that we should all stand behind the draft law. I am in favor of the draft proceeding in regular course. There is no question as to the need of men at the front, and the means taken by the Government to secure the necessary army of men is fair to all. It does not debar the volunteer, but volunteers are comparatively few and their number is inadequate, although as the old saying goes "One volunteer is worth ten drafted men."

When it became evident that the volunteer plan was too slow for the urgent needs of the country, there was nothing left for the authorities to do but to enact the Selective Draft Law, which was done without further delay. Compare conditions in this respect with those that exist in Germany, where men have no choice but to obey and there are no *"questionnaires,"* but men are quickly summoned from their various tasks and sent to the front. They are told what to do and when to do it, and there is no appeal. We are in this terrible war and few of us realize its meaning. We must oppose strength to strength, meet intrigue with intrigue and, in every way, withstand the advance of the enemy.

Reported Attempt To Have Miners Exempted

With some surprise, I read the reference made by Fred D. Hicks, in his letter, p. 1210, where he states that a committee of mine operators was appointed to go to Washington, for the purpose of obtaining a ruling, if possible, that would exempt coal miners and skilled mine laborers from the draft. While it is possible to argue in favor of both sides of this question, the fact remains that, in justice to all concerned, the coal miner has no greater claim for exemption than the workers in many other industries. Is it to be supposed, for a moment, that the authorities at Washington do not understand the situation, or are ignorant of the fact that mining labor is scarce and the mines have need of their skilled workers? It is my belief that they understand the matter from *A* to *Z*.

In the operation of our industries, I am inclined to think that we could well imitate what has been done in England and France, in this respect. In those countries, women have been utilized in many branches of industry to replace the men who have been called to the colors. In my opinion, we should do everything possible and exhaust all other means to run the mines, before attempting to secure exemption for mine workers. Several years ago when labor was scarce at the mines, I remember the plan was adopted of putting one man in charge of eight or ten men and letting him instruct them how to drill, charge and fire their holes, and set the necessary post timbers in their places. The scheme proved very successful at that time and there is no doubt that it would be an advantage now.

To the unprejudiced mind, it appears quite clear that the draft law cannot be modified to suit particular industries, and it becomes the duty of each branch of industry to adapt itself to the conditions as they exist. Let every worker do his part to win the war.

Perryopolis, Penn. R. W. LIGHTBURN.

The Mining Situation

Letter No. 5—Numerous instances can be cited showing gross ignorance in regard to coal-mining conditions, not only on the part of the general public, but also, persons in a position to be better informed, if they would use the facilities that are theirs for acquiring correct information. As proof of this statement, permit me to cite a few instances.

Last winter, the Pittsburgh Street Railways Co., in fighting for the privilege of raising its 5-c. fare, carried quarter-page ads in the city papers. In scare-head type, it was announced that the coal miners were making $10 a day, and the impression conveyed was that the miners were receiving a flat-rate of this amount. Of course, anyone acquainted with the Pittsburgh coalfield would know that this could not be the case. While there are individual instances of men drawing high pay on contract mining, the average earnings of the miner were much less than the amount named.

In one of its late winter numbers, the Saturday Evening Post carried a featured article that particularly emphasized the high wages it was stated miners were receiving. It was even claimed that a miner's wages frequently reached $15 or $20 a day. In this article, one coal company was stated to have built a village of new houses, which the miners refused to occupy, unless the company built garages for the automobiles that the miners were supposed to have owned. The article failed to give the name of the company, however.

Prizes Offered To Increase Miners' Daily Tonnage

Last summer, the United States Coal & Coke Co. offered prizes to the men working in their mines who would earn the most money, loading coal, in a two-weeks pay. The results of this contest were published in *Coal Age*, Vol. 12, p. 166. The men were stimulated by the offer to make their best efforts, with the result that the miner who received the highest prize of $50 averaged over $20 a day, for loading coal during that period. The other winners showed averages down to $10 a day. It can be said without fear of misstating the facts, which became known to many of the men and a few of the local mine officials, that two and in some cases even three men sent out coal on the same check-number and divided the returns after payday.

It is true that mine workers are making better money, today, than was possible a few years ago, but that is the case with the workers in almost every industry. Whether miners' wages are exorbitant or not, the attempt to create this impression in the public mind is quite evident. The instances that I have cited throw a helpful sidelight on the mining situation as it exists today; and it is well, in considering the numerous suggestions that are being made with a view to increasing the production of coal, that the miner should be accredited with his rightful dues.

A word in regard to the physical endurance of miners. West Virginia has a law requiring a certain number of hours that each miner must work per day. The situation becomes trying and difficult when, as occurred last winter during the car shortage, many of the mines are run little more than two days a week and occasionally less. Just before the holiday season, the Governor issued a proclamation, which was published and posted at all the mines, urging both operators and miners to cooperate in working the mines Christmas and New Year's Day.

Physical Endurance of Miners Questioned

No one will deny that there is a limit to physical endurance both in men and animals, and the suggestion of a nine-hour shift for the miner is a doubtful one. Much has been said about the miner working only a half-shift at a time, returning home with a full dinner bucket. The Pittsburgh papers have, this spring, contained interviews intended to show that coal miners were taking long layoffs, or working but a few hours a day. This was supposed to be in advocating labor conscription that would compel miners to work full time.

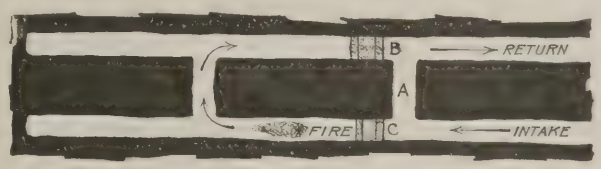
To one not acquainted with the conditions existing in mines, this suggestion would seem to be a proper one. The practical mining man knows, however, that it is frequently impossible to keep the work going so that there will always be places for the machines to cut; and, again, the miner frequently has finished loading all his cars long before quitting time. Such conditions being unavoidable, it would be senseless to ask the miner to remain underground the entire shift when he could be enjoying the sunshine and breathing the fresh air of heaven, which would invigorate him for the work of another day.

Conscription of Mine Labor

Speaking of conscription, if the Government conscripts labor, it should conscript the mines also. The coal operator should not be permitted to receive the entire benefit from a conscription of labor, compelling the men to work in the mines while the company enjoys the profits. When men are led to doubt the loyalty of coal miners as a class, they should consider the amount of money these workers have donated to Red-Cross work, and subscribed for Liberty Bonds. These amounts will compare favorably with those subscribed by workers in any other industry.

If conscription comes to the coal mines, the Government must play "no favorites," and the mines, with the workers in them, must be conscripted alike. In the draft of men for the war, the Government becomes responsible for their housing, clothing and living. In the conscription of labor for the mines, the Government must likewise be responsible for the welfare of the workers, and not leave this to the tender mercies of the coal operators.

In closing, let me say that it is my belief that much better results could be obtained in other ways than by conscription of labor, in coal mining. The work of the miner accustoms him to danger and develops an independence that resents compulsion. There is every reason to believe that conscription under private ownership would be regarded by the miner with suspicion.



Connellsville, Penn. Ralph W. Mayer.

Sealing Off Fire on Intake

Letter No. 5—I have been much interested in following the discussion, so far, of the question of the order of building the stoppings to seal off a fire on the intake of a pair of headings. This question was asked by "Ancora," *Coal Age*, June 22, p. 1173, who stated that the headings were driven in solid coal and that the fire had gained such headway when discovered that it was thought best to seal it off by building air-tight stoppings.

It is most important to choose experienced men for this work. There should be two parties so that one party can relieve the other, at intervals, and be always ready to render assistance, if needed. The plan would permit the men to rest, for a brief time, in the fresh air, and avoid the risk of being overcome by the smoke and fumes produced by the fire, while the work would be done more rapidly.

Having gotten the men and material together at a point near the fire, the volume of air passing the place

SEALING OFF THE FIRE BY STOPPINGS

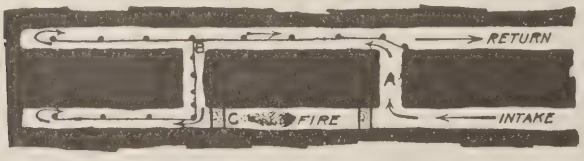
should be reduced by opening small holes in one or more of the stoppings outby. If it is possible to reach the crosscut next to the fire and marked *A* in the accompanying figure, this should be taken down, which will short-circuit practically all of the air at that point.

A temporary screen or brattice must now be erected to shield the workmen while building the first stopping on the return airway at *B*, just inside of the open crosscut *A*. I would build a good substantial stopping of two brick walls laid in mortar, filling the space between the walls with sand or road dirt. When the stopping is completed to the roof, the outside face of the brick wall should be plastered with clay to prevent any leakage or air or gas.

After completing the stopping on the return, a similar one should be built on the intake at *C*. This also should be a substantial stopping consisting of double brick walls laid in mortar and filled between with sand or road dirt and the face of the stopping plastered with clay. Care should be taken that the men have a plentiful supply of air while performing the work.

The order of building the stoppings here described is what is termed "working from the return to the

intake." The reason for proceeding in this manner is as follows: When the return stopping is built and closed first the smoke and gases generated by the fire will collect behind the stopping, and the space between it and the fire become filled with extinctive gases. Since the fire, in this case, is fed with fresh air, more carbon dioxide (CO_2) and less carbon monoxide (CO) will be formed, and the mixture be more extinctive than would be the case if the intake airway had been closed first.



On the other hand, if the first stopping is built on the intake, not only would the supply of air to the fire be limited, which would mean a larger production of carbon monoxide (CO), but the space beyond the fire would soon be filled with poisonous gases and greatly increase the danger to the men when building the second stopping on the return. There would also be the danger of an explosion occurring, owing to the fire igniting the combustible gases, which would accumulate behind the stopping on the intake, immediately after that stopping is closed. This explosion would not only destroy the stopping but would probably do much damage throughout the mine.

In some cases, it may be advisable to build another pair of stoppings outside the crosscut *A*, in which case, another crosscut should be opened by removing the stopping just outby from the point selected and the work performed in the same manner as before.

Oakview, W. Va. WILLIAM DICKINSON.

Letter No. 6—In the case mentioned in the inquiry by "Ancora," *Coal Age*, June 22, p. 1173, the fire has gained such headway that it would seem the first thing to be done is to get the men and animals out of the nime and then slow down the fan, or short-circuit a portion of the air passing in the headings where the fire has occurred. A current of 30,000 cu.ft. per min. is too large a volume to be permitted to reach the fire.

My plan of sealing off this fire is similar to that described by W. H. Noone, *Coal Age*, July 6, p. 33. I

PLACING A STOPPING INBY OF FIRE

would build a line of brattice, as shown in the figure, starting from the outby corner of the open crosscut *A*, on the return side and extending up the return airway and through the last crosscut *B*, beyond the fire.

By this means, it would be possible to carry sufficient air forward, not only to prevent the accumulation of any dangerous quantity of gas in the headings beyond the fire, but the plan would enable a second stopping to be placed at a point further in than that described by Mr. Noone and shown in his sketch on p. 33.

Let me suggest that it might even be possible, with the help of the fresh air current conducted by the brattice, to reach a point, on the intake airway, back of the fire. In that case I would attempt to build the second stopping on the intake, just outside of the last crosscut and inby from the fire. Should it be found possible to do this, the fire would be completely isolated and quickly smothered.

MATTHEW STAFFORD.

Chase River P. O., Vancouver Island, Canada.

Letter No. 7—Although this question has been discussed in *Coal Age* before and many important points brought out, it is my opinion that there is still much to be learned on the subject. The work of building stoppings to seal off a fire that is burning in mine entries is one of the greatest danger both to life and property. For this reason, the men performing the work must take no chances, but must understand the conditions that exist and what is required to insure the greatest degree of safety.

Every mining man who has had experience in dealing with fires underground knows that each case is different and that no two fires can be treated alike. My belief is, however, that when the fire is located in a pair of headings driven in solid coal and has gained such headway that it is necessary to seal off the fire, the first stopping should be built on the intake airway. It is my opinion, moreover, that only one stopping needs to be built in this case; because, when the first stopping is built and the intake airway closed, the air is completely cut off from the fire.

SUGGESTS BUILDING ONE STOPPING ONLY

To my mind, there is no cause whatever for building a second stopping in the return airway, since no air and comparatively little smoke will be passing out by the return when the air current is shut off on the intake. This, of course, assumes that the intake stopping has been properly built and sealed. Moreover, it would be difficult for workmen to perform any work on the return side, owing to gas filling the place.

When building a stopping to seal off a fire, the work must be done by practical, experienced men and be quickly performed. All necessary material should be at hand in order that there may be no delay, which would cause the quantity of air passing over the fire to be decreased little by little. It is my belief that sufficient air should be permitted to pass over the fire while the stopping is being built, to carry off the gas and prevent its accumulating. When the air is finally shut off, this should be done quickly.

The inquiry states that these headings are producing a small amount of gas and a good air current will be required to sweep away this gas and prevent its accumulation while the stopping is in course of erection. Otherwise, small explosions will be liable to occur, in the heading beyond the fire, while the work is being done. Should that happen, it would be a warning to the foreman to withdraw his men from the place.

EXPLOSIONS CAUSED BY SEALING OFF FIRES

Two of the greatest explosions that have taken place in the anthracite region occurred while walling off a mine fire. Small explosions were heard while the stopping was being built and ten or fifteen minutes after it was closed, a heavy explosion blew out the stopping and did much damage in the mine. The reason for this was that, the air current being reduced gradually,

a very explosive mixture accumulated behind the stopping with the result I have mentioned.

My plan is, therefore, in a case such as that mentioned in this inquiry, sufficient air should be kept in circulation to prevent the formation of a firedamp mixture in the heading. The first and only stopping should be built on the intake airway at the nearest point of approach outby from the fire. This stopping should be arranged with a trapdoor that will permit a good air current to pass while the work is being performed, and which can be closed quickly when the work is done. After closing the trapdoor the men should withdraw quickly from the mine.

My opinion is that, when the air is stopped suddenly, by the closing of a trapdoor, such as I have mentioned, the fire burning within will die out for the want of air. I believe this method will insure the greatest safety in the performance of the work. FRED D. HICKS.

Kingston, Penn.

Travel of Electric Current

Letter No. 1—In response to the inquiry by "Student," *Coal Age*, July 6, p. 35, asking if the flow of an electric current in a wire conductor takes place through the wire or on the surface of it, permit me to say that it is now understood that a direct electrical current permeates the entire body of the wire and is not confined to the surface.

This appears to me to be shown clearly by Ohm's law, which makes the current, in amperes, equal to the electromotive force, in volts, divided by the resistance, in ohms. Calling the current in amperes, C; the electromotive force, in volts, E; and the resistance, in ohms, R, this law is expressed by the formula

$$C = \frac{E}{R}$$

Now, for the same material in the wire and the same temperature, the resistance, per unit length of conductor, varies inversely as the size of the wire. For example, if one wire is twice as heavy as another wire of the same length, material and temperature, the resistance of the first wire, per unit length, is just one-half that of the second wire. Such being the case it follows that, for a given voltage, the current passing in the first wire will be twice that in the second wire.

To illustrate, let me assume two conductors in the form of a ribbon, say 1 in. wide, and suppose the first ribbon is $\frac{1}{32}$ in. thick while the second ribbon has a thickness of $\frac{1}{64}$ in. It is clear that the surface of these two ribbons, per unit length, is equal; yet, the first ribbon, being twice as thick as the other, will carry twice the current, under the same pressure or voltage, the two ribbons being of the same material and temperature.

Again, a solid conductor will carry the same current as one of equal weight, per lineal foot, but having the form of a hollow tube or cable, notwithstanding the surface of the latter is evidently much greater than that of the former.

It must be remembered that the foregoing applies only to direct current. In conductors carrying alternating current, there is a "skin effect," and the current density has been found to be greater in the outer portion of such conductors. However, with small wires carrying light currents such as are employed in mines, this effect is not appreciable but, in central-station work, where heavy currents are carried in large cables, the skin effect must be taken into account. For this work, in order to give the cables a greater surface they are often made with a rope or jute center. A. W. SPAHT.

Christopher, Ill.

Blue Gem Coal in Tennessee

Letter No. 1—Referring to the inquiry that appeared in *Coal Age*, July 13, p. 80, asking if the "Morning Glory Mine," of the Oneida Consolidation Coal Co. is working the genuine "Blue Gem" coal seam, permit me to say that it is not.

Having handled coal from this mine some years ago, as well as coal from other mines in that district—the Pumpkin Hollow, Jakes Tank, and the Stanley mines—commonly known as the "Paint Rock" coal, I can state with some assurance that the coal referred to here is not the genuine "Blue Gem" coal, but the "Paint Rock" seam. It is the same as that worked by the old Glen Mary Coal & Coke Co., which was known locally as the "Glen Mary" seam.

The Blue Gem seam lies just a few feet under the Jellico seam; and geologists claim that the Brushy Mountain seam, which is being worked by the Baker Coal & Coke Co., further down the Tennessee Railroad, is the Jellico seam. While I have never been to this operation, I understand it is a lower formation than the seam that the Paint Rock mines are working. This, of course, would make the Paint Rock seam much above the Blue Gem seam.

Even if the coal referred to by this inquirer was the Blue Gem seam, it could not be marketed as Blue Gem coal, because it is altogether of a different character and quality. The Blue Gem coal is the highest grade of domestic coal mined in the South. The coal is very low in ash and a quick-burning hot coal.

The Paint Rock coal is of a good quality, but heavier in ash and a slower burning coal. It will not satisfy those who have known and used the Blue Gem coal. When conditions were normal the Paint Rock coal usually brought from 15c. to 20c. less than Jellico coal, and the latter brought from 15c. to 25c. less than the Blue Gem coal. It is quite evident, therefore, that there was always a difference of from 30c. to 50c. per ton, in the price on the market, between the Paint Rock and the Blue Gem coals. H. B. BONNEY,

President H. B. Bonney Coal Co.

Chattanooga, Tenn.

Loyalty of Foreign-Born Miners

Letter No. 1—Numerous references have been made, recently, in the columns of *Coal Age*, to the loyalty of foreign-born miners. Attention has even been drawn to the assumed menace to mine safety, in the employment of enemy-alien miners. But some writers, on the other hand, have pointed with pride to the large amounts invested in War Saving Stamps and Liberty Bonds, by foreign-born miners working in our mines.

Observation and experience have impressed me with the idea that the question of increased loyalty of this class of mine employees can never reach the supreme

height until the degree of assimilation is raised to a higher standard than exists at the present time. To my mind, success or failure hinges absolutely on our ability to assimilate this class of mine labor, in a distinctly human fashion. We must learn to appreciate more readily the things that are dear to them, and be quicker to realize the peculiarities and traits of the foreigners that come to our mines.

Ellis Island, where the large majority of immigrants to this country first set foot on American soil, has been aptly described as "one of the saddest spots in the United States." It is here that foreign-born miners first come into direct contact with American civilization. When they arrive they are absolutely devoid of the principles, hopes and ideals on which our American civilization is based. Their education is extremely limited and they come to a land of which they have heard glittering tales of freedom and wealth.

It must be admitted that the majority of Americans do not meet these people with the ready sympathy and the distinctly human attitude that their condition demands, and help them to carve their own destinies as true American citizens. This is particularly true at the coal mines. Few mine officials realize that it is possible to make genuine American citizens of these foreigners seeking work and who are more willing to be taught and quicker to obey their instructions than are American miners. Many of our largest coal corporations are practically wholly dependent on their foreign-born miners for maintaining the daily production of the mines. It is not strange that the great sense of loyalty demanded of all miners by the present situation does not appeal to the foreign-born as to the native miner.

A Suggestion Worth Following

Let me suggest that, among the employees of every large coal operation, there should be a set of men who would act as missionaries of patriotic zeal among the foreign workers, in and out of the mines. These men should be possessed of a broad vision, great patience and wisdom and deal generously. In other words, they should have a heart for the foreigner and treat him as a brother—be a true friend to him, one to whom the man would learn to confide his troubles with confidence that he would help him.

In brief, let me say that one of the first steps in the assimilation of the foreigner is to gain his confidence by sympathy and helpful advice. Strive to have him realize that American ideals are of the first importance in the enjoyment of American freedom and privileges. Many foreign-born miners who have returned to their own land, after several years in this country, would not have decided to go home had they been induced to apply for their citizenship papers and been shown what is necessary to accomplish this.

In furtherance of their work along this line, these missionaries whom I have described should have every facility given them by their several companies to assist them in their efforts among the foreign classes. They should be helped to make life worth living for the foreigner, and this should be done without ostentation and with great simplicity and kindness. Every wise management must realize that a man's productiveness, whether he be native or foreign born, is gaged largely by his surroundings, and this applies not alone to the miner but to his home and family. It goes without saying that where the living conditions and the social atmosphere surrounding the miner and his home are satisfactory, he is loath to leave the place, which becomes to him in every sense a home. Permit me to quote here a few sentences from an article that I read a short time ago, and that, to my mind, suggests the best thought on this question of our relation to the foreign worker:

> What have we got to tempt the tired workman after eight or ten hours of arduous labor? In most cases simply nothing; his only relaxation is a roadhouse or saloon. What have we got for the children? In some places a school, good or bad. Have they a playground? A strip of land perhaps, which has been generously donated, thinking that our duty ended there, and forgetting entirely that our own plant would not be producing unless we equipped it with buildings and machinery.
>
> We should furnish this playground with horizontal bars, ladders, slides and swings, where the children, the bold and the timid, may get helpful bodily exercise. We should not forget some generous flower beds and shrubs, so that the eye and artistic sense may be unconsciously directed toward the beautiful things of life. Going further, let us see that these flowers find their way into the home and garden plots, that the men and women may absorb these refining influences.
>
> But it must not end here. We must train the teachers to understand and use this equipment. We should have a physical test for the teacher just as we have for the army officer, in order that he or she may direct the children properly. A teacher's berth should not be a charitable affair; it should be an office of privilege, selection and ability and subject to regular examinations for fitness.

Let me urge that we study more closely the conditions of life and previous training of our foreign-born miners. Down in Kentucky, a short time ago, I watched through my hotel window a crowd, largely composed of foreigners, who were listening to strains produced by a band and which I had difficulty to recognize as those of our national anthem. The cornetist and base drummer were two ambitious and made the rendering of the beautiful "Star Spangled Banner" anything but what would arouse the patriotic zeal of the listener.

How many of us have not observed the mirth-provoking procession of a foreign wedding, in one of our mining camps? Generally the bride and groom lead the procession, which is attended by a cornet and base drum. Is it not true that the joy of the occasion is saddened, for us, by this display, so lacking in the higher ideals of American life?

While I might enlarge further on the necessities of the foreigner's education in American ideals and customs, sufficient has been said. Let us not forget the powerful effect of motion pictures, which should be selected to inspire the foreigner with American ideals and ambitions, rather than to entertain him with blood and thunder acts and scenes.

If mine officials would interest themselves in regard to the character of pictures shown in the mining towns and camps about them, it would go far toward increasing the efficiency of their workmen. At the present time. efforts in this direction should be to increase patriotic zeal and fervor, as much hard work remains to be done before the world is finally saved for civilization.

Philadelphia, Penn. OBSERVER.

INQUIRIES OF GENERAL INTEREST

Electric Drive for Rope Haulage

We have a pair of steam engines 14 x 18 in., geared to a drum shaft carrying two drums arranged for main- and tail-rope haulage, on a slope. The engine shaft is 5½ in. in diameter and carries a pinion that engages a gearwheel on the drum shaft, the ratio of gearing being 3:1. The diameter of each drum is 5½ ft. and the engines are making 60 r.p.m.

The slope is 2600 ft. long and has an average grade of 5½ per cent., except at one place where the grade is 10 per cent., for a distance of 100 ft. We have been using a ¾-in. steel haulage rope. The mine cars weigh 1500 lb. each and carry 3000 lb. of coal, making the weight of the loaded car 4500 lb.

It is proposed to replace the steam engines now in use with an electric drive, and to haul trips of 32 cars, making 5½ trips an hour. What I want to ask is, what power of motor will be required for this work? Also, is the 5½-in. engine shaft strong enough?

———, Ala. ENGINEER.

The first step in the solution of this problem is to ascertain the maximum load on the rope when hauling a loaded trip that has reached the 10 per cent. grade. For the purpose of this calculation, we will estimate the gravity pull of the entire trip of 32 cars, for the maximum 10 per cent. grade, although a portion of the trip only will occupy that grade at one time, the grade being only 100 ft. long.

The total weight of a loaded trip is 32 × 4500 equals 144,000 lb., and the gravity pull for a 10 per cent. grade may be taken as $\frac{1}{10}$ of this weight, or 14,400 lb. We will assume a track resistance of, say 15 lb. per ton, which gives 15(144,000 ÷ 2000) = 1080 lb. Ingoring, on this light grade, the weight of the rope itself, the load on the rope is the sum of the gravity pull and the track resistance, which is 15,480 lb. or 7.74 tons. Taking six-strand, seven-wire, steel haulage rope, the diameter of the rope required for this load is

$$d = \sqrt{\frac{fL}{37}} = \sqrt{\frac{5 \times 7.74}{37}} = say\ 1\ in.$$

Since the engine shaft has a speed of 60 r.p.m. and the ratio of gearing is 3:1 the drums are making 60 ÷ 3 = 20 r.p.m. Adding the diameter of the rope to the diameter of the drum gives for the effective diameter of winding 5 ft. 7 in., or 5.58 ft. The circumference corresponding to this diameter is 3.1416 × 5.58 = 17.53 ft. If the drum is making 20 r.p.m., the speed of winding or rope speed is 20 x 17.53 = say 350 ft. per minute.

The power required to haul a loaded trip, at this speed, on a 10 per cent. grade, assuming an efficiency of the motor of 90 per cent will then be

$$H = \frac{15{,}480 \times 350}{0.90 \times 33{,}000} = 182+\ hp.$$

In electric haulage this power would be expressed as 182 × 0.746 = 136 kw. For this power, the diameter of the engine shaft, run at the speed of 60 r.p.m. may be estimated as

$$D = \sqrt[3]{\frac{100H}{n}} = \sqrt[3]{\frac{100 \times 182}{60}} = 6.7,\ say\ 7\ in.$$

We would therefore suggest the installation of a motor capable of producing say 150 kw. The 5½-in. engine shaft should be replaced by a shaft 7 in. in diameter, and a 1-in. steel haulage rope should be used for this haulage.

Ventilating a Gassy Slope Mine

We are about to open a slope mine in a seam having a general dip of 6 per cent. and generating large quantities of explosive gas. Before deciding on the general plan of working, I want to ask for information in regard to the best method of ventilating such a mine.

Tower Hill, Va. MINE FOREMAN.

A slope mine opened in a gassy seam should have not less than three main slopes driven on the full dip of the seam. The center opening should be made the main haulage road and intake for the entire mine, while the two side openings serve as return airways for their respective sides of the mine. These openings should all be 6 x 10 ft. in section.

The mine should be ventilated on the exhaust system; and, for this purpose, a centrifugal fan should be installed at the mouth of one of the return airways, which should be connected underground by crosscuts in the slope pillars and an overcast on the main haulage road. The fan should have a capacity capable of supplying the volume of air required for the entire mine, under a water gage varying from 1 to 2 in. In order to provide against the possible failure or breakdown of the fan, a duplicate fan should be installed, either at the same opening or at the mouth of the other return airway. Only one of these fans should be operated at the same time, the other being held in reserve ready for immediate use in case of emergency. In a gaseous mine, it is always safer to provide duplicate means of ventilation, to provide for any possible emergency.

The general plan of working the seam described by this correspondent will involve the driving of pairs of cross-entries to the right and left of the main slope. The first pair of these cross-entries must be driven about 150 yd. below the mouth of the main entry, provided the roof of the seam will permit rooms to be driven 75 or 100 yd. in depth. The first right and first left entries should be haulage roads and intakes, while the second right and second left entries are made return aircourses for their respective sections of the mine. Rooms should be driven to the rise of the cross-entries. The return air is conducted by means of an overcast or air bridge over the return airway. We have only treated this inquiry in a general way and shall be glad to have our readers' comments and suggestions.

EXAMINATION QUESTIONS

Mine Foremen's Examination, Hazleton, Penn., Apr. 23, 1918

(Selected Questions)

Ques.—How may a squeeze or creep be stopped and the damage it is calculated to do be localized?

Ans.—The only practical method that will prove effective in stopping or localizing a squeeze that has already begun in a mine is the plan, now quite generally adopted, of quickly drawing adjacent pillars and all timber left standing in adjoining abandoned places. If this does not cause an immediate roof fall, some means should be adopted to produce that effect at the earliest opportunity. It may be necessary to place one or more shots in the roof to start the fall.

Solid timber cribs can sometimes be utilized at points where the pillars are weak, in order to prevent the spread of the damage in that direction. However, the plan of setting timbers to prevent the progress of a squeeze in mine workings will generally be found to do more harm than good. What is required is to produce a heavy fall of roof so as to relieve the pressure on the pillars.

Ques.—What arrangements would you make to prevent cars from running over the top of slopes or shafts?

Ans.—Safety blocks and derailing switches should always be installed at the head of a shaft or slope. These should be automatic so that they will always be set to prevent cars from reaching the shaft or slope, except as they are thrown by a lever arranged for that purpose. In addition to these devices, the top of a shaft should always be protected by safety gates to prevent persons from falling down the shaft.

Ques.—Give the reasons for putting a cap-piece on a prop and state what should be the size of the cap and the kind of wood to give the best results.

Ans.—A good cap-piece not only gives a better bearing for the top of the post against the roof and distributes the pressure, but it also affords a means of showing any increase of roof pressure, which is indicated plainly by the crushing of the cap. This also has the effect of binding the top of the post together, thus preserving and strengthening the post. A cap-piece also expedites the setting of a post.

Cap-pieces should be slightly broader than the top of the post. They should never be less than 6 or 8 in. in width and from 18 to 24 in. in length, depending on the character of the roof and the pressure. Cap-pieces should not be less than 2 in. in thickness and made of soft wood, so that they will yield more readily under the pressure and prevent the furring of the top of the post.

Ques.—What regulations would you adopt for the use of safety lamps, in a mine where gas is given off freely?

Ans.—A thoroughly equipped lamphouse should be provided on the surface, a short distance from the mine entrance. The lamphouse should be in charge of a competent man who would be responsible for the delivery of all lamps to the workmen, in good and safe condition, in return for a check indicating the number of the lamp used by the man. The lamps should be kept in a suitable lamprack, having hooks or pigeon holes numbered to correspond to the numbers on the lamps. All lamps received from the workmen at the close of the shift are first cleaned, filled and trimmed. Each lamp is then carefully examined and returned to its proper place in the rack, ready to be lit and delivered to the man, in the morning, on presentation of his check.

All lamps should be owned by the company and be of an approved type. Every lamp must be provided with a lock or fastening that will reveal any attempt on the part of a man to tamper with his lamp. Each man should be held responsible for the condition of the lamp he has used. No man should be permitted to use a safety lamp or to hold a check for a lamp until he has proved that he is capable of handling and using a safety lamp.

The fireboss should examine each man to determine whether or not he is capable of using a safety lamp. The men should be given all needed instructions to insure the safe use of lamps in the mine. If a lamp is extinguished by accident, while the man is at work, it must be taken to a relighting station, and no attempt should be made by the man to light the lamp himself. Any violation of the rules regarding safety lamps and their use should be punished by a suitable penalty.

Ques.—What kind of haulage would you recommend to replace animal haulage where the mine has been extensively developed, and why?

Ans.—Some form of mechanical haulage should be adopted on the main roads, as early in the development of a mine as practicable. This should consist of some kind of rope or locomotive haulage, depending on conditions in the mind. Where there are no grades that would prevent the use of locomotives, this type of haulage will generally prove more elastic and serviceable than rope haulage. The latter, however, will be required where the grades on the main roads would interfere with the efficiency of locomotive haulage, by reducing the number of cars that could be hauled in a trip and otherwise delaying the movement of the coal to the foot of the shaft or slope.

The use of storage-battery locomotives is rapidly increasing on gathering hauls, in large mines, and is giving good satisfaction. Their use in the workings to replace mules possesses the advantage of eliminating the refuse deposited by the mules, and thus clarifying the air. Also, a motor absorbs no oxygen and produces no carbon dioxide as does the breathing of the animals used on gathering hauls. Compressed-air-locomotive haulage, while furnishing fresh air in the workings, requires the installation of a good compressing plant and pipe lines for the transmission of the air to the working face. It is of advantage to operate the drills and coal cutters at the face with the same power as employed for haulage, which conditions alone can determine.

COAL AND COKE NEWS

Harrisburg, Penn.

Approval has been given by the Governor, the Attorney General and the Commissioner of Health of plans submitted to the State Department of Health for the establishment of model towns in two counties in southwestern Pennsylvania, the corporations which are providing housing for their employees recognizing that it is best to get started right and to seek the advice of the state's experts. The companies which submitted plans during the week were the Ellsworth Collieries Co., which is building extensions to mining towns in Washington County, and which presented plans for modern water and sewerage systems, and the Pennsylvania Rubber Co., which is starting a large addition to the borough of Jeannette, Westmoreland County, to house its workmen.

Every month the state authorities are being called upon to help in the planning of towns by corporations which want their people housed right and given healthful environment with adequate water supplies, instead of going through the old haphazard system of building houses to meet demands and then regretting the mistakes made through not obtaining the right kind of advice and the approval of state authorities.

On account of uncertain credit conditions, now that the Government supervision of coal distribution is well under way, shippers of bituminous coal are seriously considering pressing for such reforms as will guarantee payment on all shipments. War industries are said to be notably lax in paying their coal bills, regardless of the fact that the operators must pay the miners on time or have a strike on their hands.

Another uncertain condition is with the railroads, as the operators are compelled to supply the railroads with 100 per cent. of their requirements, and practically all declare they cannot get their money. The railroads argue they haven't the money, in view of the fact that the Government has not yet started rental payments. To some of the shippers the railroads have not paid a cent for two or three months, and these operators are put to extremes to get credit extensions to permit them to conduct their business.

Uniontown, Penn.

Opposing financial interests have taken their battle for control of the Thompson Connellsville Coke Co. into the Fayette County Court. J. H. Hillman, Jr., of Pittsburgh, who recently acquired more than 8000 of the company's 30,000 shares of capital stock, is seeking to oust the present officers, J. P. Brennen, president; A. G. Livengood, vice president; and W. G. Rock, secretary and treasurer. Testimony was taken this week before Judge J Q. Van Swearingen in a preliminary injunction order restraining the annual meeting of stockholders scheduled for May 6, last, until the rights of the litigants are determined. The evidence showed that a few days before the scheduled meeting Mr. Hillman acquired a block of 5750 shares placed as collateral by J. V. Thompson with the First National Bank of Pittsburgh. When he sought to have the stock transferred upon the company's books, witnesses testified, the officers declined to meet the request on the ground that the books had been closed until after the election. The litigation resulted. No decision has been handed down.

The Connellsville region had a normal week in coke production, as a normal week is now figured, with the impetus given the operation of the plants by Government supervision. The region's output of coke was 348,296 tons, according to statistics prepared by the Fayette fuel administration, or a decrease of 2000 tons in last week's output. Despite the local coal car shortage there was a record production of 168,507 tons of coal, an increase of 9852 tons over the preceding week. While not plentiful by any means, the railroads by a little juggling are providing operators with 100 per cent. coke cars, and every effort is being made to load and ship cars at the earliest possible moment after placing, to further conserve the car supply.

Altoona, Penn.

A meeting held by the Central Pennsylvania Coal Producers' Association at Altoona, Penn., on Tuesday, July 16, was the most successful meeting of coal operators ever held in central Pennsylvania. Over 350 men, representing 90 per cent. of the tonnage in central Pennsylvania, were present. The meeting was addressed by James B. Neale, Director of Production, United States Fuel Administration; A. W. Calloway, Manager of Distribution, United States Fuel Administration; G. N. Snider, Traffic Adviser, United States Fuel Administration; J. D. A. Morrow, Director of Distribution, United States Fuel Administration; Rembrandt Peale, Bituminous Adviser, United States Fuel Administration; Charles O'Neill, Secretary of the Central Pennsylvania Coal Producers' Association.

The meeting was presided over by Harry Boulton, of Clearfield, president of the Central Pennsylvania Coal Producers' Association. All of the addresses called attention to the shortage of coal and the necessity for greater production. Mr. Neale explained the campaign about to be launched by the United States Government to increase production. This campaign will include many of the features of the campaign launched by the Central Pennsylvania Coal Producers' Association several weeks ago, some of the outstanding features being pledge cards and badges to the miners for efficient service.

Attention was called to the fact that deferred classification of miners until next spring had been asked for and enforcement of national prohibition during the period of the war.

Charleston, W. Va.

The labor supply in several districts of the state is unable to keep pace now with the car supply, both because there is to some extent a less number of miners than are needed and because some miners are indifferent as to whether they work or not. Cars supplied in nearly all the districts of the state are ample for all the coal that is being mined. In short, the supply in many regions is 100 per cent.

The production of 50,000 tons of coal was lost, it is estimated last Wednesday, when all miners in the New River district supplied with power by the Virginian Power Co. were without power and consequently were forced to suspend operations. The trouble is believed to be due to defective construction of transmission lines, since whenever there is a rainstorm the power supply is curtailed. Coming just at a time when New River operators were endeavoring to push up production to top notch, the enforced shut-down was disheartening and demoralizing. Such a contingency was especially disappointing when there was a 100 per cent. supply of cars on hand. The power shortage also affected production in the Kanawha and Winding Gulf regions.

Fairmont, W. Va.

Like other districts, the Fairmont district has apparently not fully recovered from the celebration of the Fourth among the miners, since reports show that there were 528 men idle in the district; for instance, last Tuesday, although there were only 1243 cars in the region on that day, such mines as were shut down were not idle due to an inadequate car supply but because there were no miners to man such mines. The first day's supply for the region—1675 cars—was slightly in excess of normal requirements. Mines in this region, it was announced at a meeting of Kanawha district operators, will within the next few months be expected to furnish 100,000 tons of coal a month to the Government powder plant at Nitro. The mines along the Kanawha & Michigan R. R., which passes through Nitro, have been designated to supply the coal next month and will be required to furnish 25,000 tons, increasing that tonnage within the next few months until 100,000 tons are reached.

Despite many unfavorable conditions the production for the week ending July 13 in the Kanawha district reached the high point of the year, being 205,436 tons, or an increase of 60,000 tons over the previous week. The increase may be attributed to the number of hours worked—6389 in all. The car shortage caused the loss of only 148 hours, labor shortage being responsible for 537 hours. Many mines in the Kanawha district were shut down last Wednesday because of power failure. Up until July 16, 21,885 loads of coal had been shipped from the district, 20,788 empties being received.

PENNSYLVANIA

Anthracite

Hazleton—Hard-coal companies in the Lehigh region have collected the names of all mine workers who left on July 23 with the various draft quotas for Camp Lee, so that substitutes can be trained to take their positions. Keeping up tonnage is the chief aim of the coal operators, who report that their labor resources are dwindling all the time. The G. B. Markle Co. runs its mines with 51 per cent. of the staff it had in 1913, and the Lehigh Valley Coal Co. is reduced to 75 per cent. of its pre-war strength.

Millersburg—To prevent further removal of river coal from a bed in Wiconisco Creek, the Juniata Public Service Co., furnishing electric current in the upper end of Dauphin, and in Perry and Juniata Counties, has petitioned the courts for a preliminary injunction against D. W. Romberger, et al., directing them to discontinue dredging and removing coal. The company contends it purchased a tract of 19 acres along the creek in order to work the coal bed and that the line of the property extends along the opposite side of the creek. The Romberger firm has been removing about 25 tons of river coal daily.

Tresckow—A fanhouse of the Lehigh and Wilkes-Barre Coal Co. at its No. 21 colliery was destroyed by fire on July 16. The blaze was started by sparks from a passing mine locomotive.

Tamaqua—A contribution of $25,000 has been made by the Lehigh Coal & Navigation Co. to the war chests which are being established at Tamaqua and Panther Creek Valley towns in the vicinity.

Oakdale—Effective July 16, the G. B. Markle Coal Co. has placed in operation its new breaker in the anthracite coal fields near Oakdale. The plant, entirely constructed of steel, will be used for the preparation of fuel taken from the culm banks, and will provide a daily capacity of about 800 tons. The company has arranged for the temporary employment of about 200 men thrown out of work by the destruction by fire of the Harleigh-Brookwood coal breaker near Hazleton, July 13. The Harleigh-Brookwood company is planning for the immediate reconstruction of its plant.

Pittston—Considerable rivalry exists at the different collieries of the Pennsylvania and the Hillside Coal and Iron companies, between the several superintendents regarding the monthly tonnage of coal at each colliery. The Butler is one of the leading collieries and since assuming control James C. Johnson, the superintendent, has had remarkable success in increasing the daily output. For the month of June, 1918, prepared tonnage was shipped amounting to some 74,000 tons, a gain of over 12,000 tons for same month in 1917.

Bituminous

New Castle—Coal is now being mined in Lawrence County by the stripping process. A mine of considerable proportions has been opened by this method six miles north of this city.

Pittsburgh—The Ellsworth Collieries Co. has submitted plans to the State Board of Health for permission to establish a new town in its bituminous fields in Washington County. The company proposes to build a model settlement with dwellings for its employees.

Steelton—A battery of 80 coke ovens was charged July 8 at the Bethlehem Steel Co., Steelton, Penn. The new battery of ovens will be able to produce about 18 cars of coke daily, which will bring the daily output up to 45 cars of fuel. The H. Koppers Co., of Pittsburgh, erected the ovens. The work of construction covered

a period of 18 months. Due to the scarcity of materials, the work was held up at intervals; thus the job dragged over the stated time of 12 months.

Somerset—One man was killed and a dozen others were injured when the powder magazine of the Black Brothers' Coal Co., at Blackfield, three miles east of Rockwood, exploded on July 17. It is believed that a foreigner employed as a night watchman carried a lighted torch into the magazine. Windows in miners' homes nearby were broken and the occupants cut by flying glass.

Milesville—The United Coal Corporation is building a new railroad tipple at its Ella mine, near here, on the Pittsburgh & Lake Erie R. R., with a belt conveyor for river loading on the Monongahela River, to replace the old rail and river tipple. Pihl & Miller, contractors, of Pittsburgh, are doing the work.

WEST VIRGINIA

Beckley—By Aug. 1, The Board Smokeless Coal Co. expects to have its plant at Pemberton in operation, a new tipple being now under construction.

Mabscott—Much new equipment has been added to the plant of the Bower Coal Co. at this place, including new mining machines, three locomotives and 250 mine cars. A new two-track tipple is under construction.

Morgantown—From additional information obtained, it appears that the State Hill Coal Co., recently formed, has arranged to take over and operate a developed team track proposition, located at the edge of Morgantown, and will produce about 200 tons per day. The plant to be taken over is now operated by the Pollock Coal Company.

Williamson—The mining and shipment of coal will be begun by the New Howard Coal Co. before the end of the month, the new plant of the company, of which F. L. Schoen is general manager, having been virtually completed.

Hawk's Nest—Lumber has been received by the Gaymont Coal Co. to be used in the construction of a new tipple at the company's plant at this place, and work will be begun on the tipple at once. The company at present is shipping 300 tons of coal a week.

Glen Jean—The Collins Colliery Co., of Glen Jean, is preparing to have in the near future 100 ovens in blast for the production of foundry coke. The old coke ovens have been repaired and a new crusher and storage bins have been completed. It has been five years since any coke was manufactured at this point.

Thurmond—After being out of commission for some time, the mines at Beurytown, on Sewell Valley, renewed operations last week, repairs to the monitors, recently damaged, having been completed.

Logan—With the completion of two miles of railroad on Beard Mill Fork of Dingess Run Creek, the Jones Coal Land Co. is shipping coal from its Isabel Mine No. 1. The company expects to be able to begin loading coal from its No. 2 mine in a short time.

OHIO

Shawnee—A loss of $10,000 was caused and 200 men thrown out of employment by the burning of No. 3 coal chute, of the Hocking Block Coal Co. Rebuilding was started at once.

Nelsonville—The Packard Coal Co., recently incorporated with Columbus capital, has purchased from Lampman & Juniper a tract of 160 acres located near Nelsonville on the Hocking Valley Ry. It contains a good seam of No. 6 coal. The operating plant will be enlarged in order to double the output. Officers of the company are M. L. Yuster, president and treasurer; Richard Patton, vice president, and C. F. Bookman, secretary.

New Straitsville—A deal has been closed whereby Harry Spencer has secured title to a tract of 80 acres of No. 6 coal on Lost Run, in the heart of the Hocking Valley field. The tract contains a 12-ft. vein and is one of the most valuable of the smaller tracts in this vicinity. The property was purchased from the Hazelton heirs and was closed by E. E. Hazelton, of the Dean Coal Mining Co. Mr. Spencer also controls the Gem Coal Co., which adjoins.

ILLINOIS

East St. Louis—East St. Louis coal dealers have adopted a "no-credit" rule. The East St. Louis Coal Dealers' Association, at its last meeting, passed a resolution that members hereafter will not book orders unless they are accompanied by cash. More than that, consumers who still owe for last winter's coal will not be able to get any for next winter, even for cash, until they pay what they owe. J. H. Thomas, president of the association, says that delinquents will not be able to buy a single load of coal until old scores are settled.

Bethalto—Threshing is being hindered in this section by the difficulty of getting coal for the engines. Formerly the thresher demand was met by small mines scattered through the wheat belt, which stored enough coal during the spring to meet the heavy demands of the threshing season. But this spring these mines have sold all the coal that they could turn out as fast as they could turn it out, and no storing has been done. Farmers wait all night at the mines to get coal the next morning, and in many instances they have had to haul coal long distances to keep the thresher going.

KENTUCKY

Harveyton—The Hazard Jellico Coal Co. has just installed a new coal-cutting machine in its mine at this place, the machine being of a new type and the first installed in Perry County.

Hazard—The Hazard Coal Co. and the Powell-Hackney Grocery Co. are preparing to erect a large commissary store at Hazard, and will arrange for both concerns to have their offices in this building.

Madisonville—The Louisville & Nashville Railroad Co. has refused to furnish cars to four small wagon mines in Hopkins County, these being the Dixie Bee, Medlock, Hawkins and Ferguson mines, near Morton's Gap. The railroad company alleges that the mines load only about one car a day, and sometimes let cars stand for several days at a time, with the result that it can't furnish them equipment while other large mines are without cars, which can use them immediately. The mine owners have taken the matter up with D. W. Gatlin, County Fuel Administrator.

TENNESSEE

Clairfield—The Standard Jellico Mining Co., which recently filed notice of an increase in its capital to $50,000, is planning for immediate work on the development of 800 acres of coal properties in the Clairfield district. It is estimated that the works will have a daily capacity of 150 tons.

Foreign News

Nanaimo, B. C.—The Canadian Western Fuel Co.'s new mine, situated near here, and two shafts of which are being sunk to tap the famous Wellington seam, will be known as the Wakesiah mine. To reach the seam the shafts must be sunk 350 ft. The concrete collars are in and sinking has progressed to a depth of about 50 ft. in the hoisting shaft. Plans have been prepared for the various buildings and machinery and mine yards. The mine will be up to date in every respect and will be shipping coal before the end of the year. The company has three other producing mines yielding a monthly tonnage of approximately 65,000 tons and mining from three seams, —the Douglas, Newcastle and Wellington.

Personals

Ray Heller has been made manager of the Columbus, Ohio, office of the Lake Erie Coal Co., which has recently been opened in the Columbus Savings and Trust Building.

E. E. Hazelton, assistant manager of the West Virginia Rail and River Coal Co., of Columbus, Ohio, and the Dean Coal Mining Co., of Columbus, Ohio, began life as a soldier in training at Camp Sherman, Chillicothe, Ohio, July 23.

Oliver W. Ramsay, city fuel administrator, Perth Amboy, N. J., has been appointed a member of the Conservation Bureau of the Federal Fuel Administration. The Bureau has been organized by Richard C. Jenkinson, federal fuel administrator for the state, to encourage conservation of fuel.

B. F. Phillippe, of St. Davids, Philadelphia, assistant to the purchasing agent of the Pennsylvania R.R. in charge of the purchase of fuel and building materials, has been appointed fuel distributor of the central advisory purchasing committee, with offices in Washington, having been detailed to handle matters pertaining to coal distribution and contracts for the railroad administration.

Arthur H. Young, director of the American Museum of Safety since Jan. 1, 1917, has resigned to take charge of the Employee Relations Department of the International Harvester Co. He will take up his new duties immediately. Although giving up the actual direction of the museum's work, Mr. Young will continue to be closely concerned with its affairs, for he has been elected to the vice presidency, succeeding the late Dr. Frederic R. Hutton.

Obituary

Thomas F. Righter, of Mt. Carmel, Penn., one of the largest independent coal operators in the anthracite region, died at his home on July 15. He was 70 years of age. Mr. Righter was interested in a number of coal companies in the Schuylkill region.

Latelle Graney died July 13 at 7 p. m. in the Sheltering Arms Hospital at Hansford, W. Va., after an operation for appendicitis. He was prominently connected with the coal-mining industry as general manager of the Long Branch Coal Co. and the East Gulf Coal Co., besides having interests in various other mines. Interment was made July 15 in the Mount Hope cemetery.

Coming Meetings

National Commissary Managers' Association will hold its ninth annual convention Aug. 6, 7 and 8 at Birmingham, Ala., with headquarters at Hotel Tutwiler. Secretary, D. J. Eichoff, 801 Manhattan Building, Chicago, Ill.

American Institute of Mining Engineers, Colorado meeting, Sept. 2 to 7. Plans include a day at Denver, one at Cripple Creek, one day at Pueblo and one day at Leadville. Secretary, Bredley Stoughton, 29 West 39th St., New York City.

Furnace Charging Apparatus. S. H Bunnell and C. G. Peterson, assignors to Griscom-Russell Co., New York, N. Y., 1,265,736. May 14, 1918. Filed Jan. 26 1916. Serial No. 74,424.

Publications Received

Annual Report of Coal Mines, State of Alabama, 1917. By C. H. Nesbitt, Chief Mine Inspector, Birmingham. Illustrated, 84 pp., 6 x 9 inches.

Maximum Base Prices, Differentials and Extras on Iron, Steel and Nonferrous Products. Penton Publishing Co., Cleveland, Ohio. Pp. 75 + index. Price, $1. A revised and amplified booklet giving the complete schedules of maximum prices on iron, steel and nonferrous products as fixed by the Government, which are now in effect. This booklet is practically the only up-to-date price manual on iron and steel now in circulation, as the numerous changes have rendered obsolete those previously issued.

Trade Catalogs

W-S-M Coke Oven Machinery. Wellman-Seaver-Morgan Co., Cleveland, Ohio. Bulletin No. 10, Pp. 8; 8½ x 11 in.; illustrated. Describes combination machines for extracting, leveling and coke pushing.

Type IL Series Transformers for Street Lighting Service. General Electric Co., Schenectady, N. Y. Pp. 9; 4 x 7 in.; illustrated. Data covering the characteristics, construction, dimensions, etc., of different types of series transformers.

Rego Welding and Cutting Apparatus. Bastain-Blessing Co., Chicago, Ill., Pp. 29; 8 x 10½ in.; illustrated. Catalog covers the Rego line of welding and cutting apparatus, lead burning equipment, regulators, etc. One noticeable feature is emphasized, and that is the flashback, the most annoying and costly habit of oxyacetylene torches, has been eliminated.

Gibbs Self-Contained Oxygen Rescue Apparatus. Mine Safety Appliances Co., Pittsburgh, Penn. Two-color folder. Describes and illustrates the "only oxygen rescue apparatus developed by Americans and manufactured in America." It is claimed that the objectionable and unsafe features found in other types of oxygen apparatus have been eliminated in the new Gibbs.

C-H Equipment for Mines. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Pp. 4; 8½ x 11 in.; illustrated. The equipment shown and described in this 4-page pamphlet consists of sectional charging equipment for miners' lamp batteries. Space is also devoted to illustrating and describing charging equipment and control apparatus for mine locomotives. A mine installation of automatic motor-driven pump control is also shown.

New Incorporations

St. Paul, Va.—The Edge Coal Co. Capital, $10,000. To build and operate a coal-mining plant. J. H. Lynch is the principal incorporator.

Willard, Ky.—The Black Raven Coal Co. Capital, $100,000. To operate coal properties. Incorporators: H. W. Norris and J. B. Walker.

Pittsburgh, Penn.—The Stanton Coal Co. Capital, $100,000. To operate coal properties near Bolivar. William S. Byers is the principal incorporator.

Clearfield, Penn.—The Morgan Run Mining Co. Capital, $50,000. To operate coal-mining properties in Morgan Run district. A. D. Bigler, Clearfield, principal incorporator.

Sassafras, Ky.—Montgomery Creek Coal Co. Capital, $100,000. To develop coal properties near Montgomery Creek. Incorporators: G. W. Smith, S. B. Snyder and J. W. Reedy, Lexington, Ky.

Nelsonville, Ohio—The J. W. Fenton Coal Co. has been incorporated with a capital of $100,000 to mine and sell coal. The incorporators are J. W. Fenton, Robert J. Smith, F. H. Hertel, M. B. Gilbert and E. F. Horton.

Columbus, Ohio—The Packard Coal Mining Co. has been incorporated with a capital of $50,000 to mine and sell coal. The incorporators are M. L. Yuster, Richard Patton, E. E. Fox, W. J. Etchen and C. F. Bookman.

Canton, Ohio—The Chestnut Ridge Coal Mining Co. has been incorporated with a capital of $5000 to mine and sell coal. The incorporators are H. J. Schory, Elmer Schellhase, Charles Jordan, Russell J. Burt and J. Schully.

Butler, Penn.—The Clover Coal and Coke Co., incorporated in Delaware, $300,000 capital. To operate coal properties in the vicinity of Butler. Incorporators: D. Ferguson, H. C. Scherf, Pittsburgh, and J. A. McCaffery, Butler, Penn.

Steubenville, Ohio—The S. M. Hudson Coal and Coke Co. has been incorporated with a capital of $200,000 to mine and sell coal and coke. The incorporators are S. M. Hudson, Mary R. Hudson, Jane L. Branyen, William J. Bertram and L. A. Whitaker.

New Straitsville, Ohio—The Southern Perry Coal Co. has been incorporated with a capital of $12,000 to mine and sell coal. The incorporators are John W. White, Charles C. White, David M. Watkins, Frank F. Thomas, Jr., Sam Spencer and Thomas Watkins.

Indianapolis, Ind.—The Owen Block Coal Co., a Delaware corporation, has qualified to do business in this state. The amount of $100,000 of its capital stock is represented in Indiana. The business of the company is to mine and ship coal. R. W. McBride, of Indianapolis, is named as agent.

Morgantown, W. Va.—There is to be further development of the coal fields of Monongahela district by the State Hill Coal Co. of Morgantown, which has been incorporated with a capital of $50,000. Those chiefly interested in the company are James R. Moreland, J. H. Wright, J. J. Yoke, L. C. Snyder and Robert E. Guy, all of Morgantown.

Birmingham, Ala.—The Liberty Coal Mining Co., of Dora, Walker County, was incorporated recently with a capital stock of $4000. J. T. Baird, Lottie Baird and O. L. Jones were named as incorporators.

Another Walker County company filed articles of incorporation, known as the Emergency Coal Co., of Carbon Hill, capitalized at $2000. Papers were filed by W. S. Thornton, M. B. Thornton and J. W. Little.

Louisville, Ky.—The Walnut Coal Co., of Louisville, capital $3000, has been incorporated by W. F. Burwinkle, Edward E. Weber, J. S. Miller and R. E. Gordon. The company will operate a wholesale coal yard in Louisville. Miller and Gordon are connected with the recently incorporated Gordon-Miller Coal and Coke Co., with mines in eastern Kentucky, and Gordon is also head of the Trace Branch Coal Co., Barbourville, Ky., operating a small wagon mine. The latter concern has increased its capital from $1500 to $5000. Offices of the company have been established in the Lincoln Bulding, Louisville.

Industrial News

Madisonville, Ky.—The Coil Coal Co. has leased about 750 acres of coal properties in the Madisonville district, and is planning to commence operations at an early date for development.

Philadelphia, Penn.—The Hunter Pressed Steel Co., the office and works of which have been located at Orthodox and Horrocks Sts., has moved into its new quarters at Lansdale, Penn.

Primrose, Penn.—The Carnegie Coal Co. is reconstructing its Primrose tipple and has contracted with the Roberts & Schaefer Co., engineers and contractors, Chicago, for another Marcus picking table screen.

New Orleans, La.—The Municipal Dock Commission is considering plans for the construction of new elevators and coal-handling apparatus for cargo coal at the city dock. E. B. Thompson is president of the commission.

Columbus, Ohio—The Coal Ridge Coal Co., which has opened a branch in Columbus under the name of the Erie Coal Co., the selling organization, will soon open a second stripping operation in the Cambridge field. The producing mine is a stripping proposition and the production is unusually large.

Ages, Ky.—The Adair Mining Co., which recently completed its organization, is planning to commence operations at once on the development of extensive coal properties in this district, to have a capacity of about 250 tons daily. The company recently filed articles of incorporation with a capital of $30,000. J. E. Adair of Harlan, Ky., is president and manager.

Chattanooga, Tenn.—It is reported that the majority of the local coal dealers have orders booked up which will take care of receipts until some time in September, while additional orders are steadily pouring in. Many of the dealers are just getting orders placed during the first part of May. A regular winter rush for coal has characterized spring and summer business.

Dora, Ala.—The Southern Cotton Oil Co., Birmingham, is planning for the installation of a quantity of mining equipment for the development of coal properties in this district for the furnishing of coal for the operation of its various mills. The company has acquired a site of about 920 acres and is planning to have a daily capacity of approximately 200 tons. It is estimated that the equipment will cost in the neighborhood of $100,000.

Charleston, W. Va.—Dr. E. B. Stephenson and James S. Lakin have recently closed a deal by which they disposed of the 1500-acre tract of coal lands at Queens Shoals, known as the Queen Shoals Land Co. property. The consideration was nearly $100,000. The land was purchased by the Fire Block Coal Co., which is controlled by Detroit and Cleveland men. J. W. Miller and A. J. Saltzer will operate the property, on which one mine already is being worked.

Louisville, Ky.—It has been reported that 3,000,000 bushels of coal are coming down the Ohio River from the Kanawha district of West Virginia, arrangements having been made to manipulate the series of locks and dams to furnish an artificial stage to carry the coal as far as Louisville. Part of the big river shipment will be dropped off at Cincinnati, Madison and upper river points, while a portion of it will go to Jeffersonville and New Albany, Indiana.

Toledo, Ohio—Considerable activity has developed in the lake trade, as is shown by the records of loadings at the Hocking Valley and Toledo & Ohio Central docks during the week ending July 20. During that week the Hocking Valley docks loaded 168,000 tons as compared with 160,000 for the previous week, making a total of 1,663,507 tons for the season. The Toledo & Ohio Central docks loaded 59,000 tons as compared with 45,000 tons the previous week, making a total of 809,000 tons for the season.

Indianapolis, Ind.—New retail prices for Indiana coal, resulting from increased rates, have been announced. An advance of from 15c. to 25c. a ton is noted. Indiana lump coal, formerly quoted at $5.50 a ton by local retail dealers in Indiana, is now priced at $5.65. Indiana egg has been raised from $5.40 a ton to $5.65 a ton, and Indiana mine-run coal is now advanced from $5.15 to $5.45 a ton. An increase of 75c. a ton is noted in the newly quoted price of Brazil block coal, but this larger increase is caused by the fact that this grade of coal comes from mines remote from the railroad, necessitating long wagon hauls for delivery.

Detroit, Mich.—Because of the increase in passenger fares on railroads under Federal control, Michigan's largest coal mine and some of the others are shut down. Some of the miners insist the operators should pay the increase in railroad fare, amounting to about 10 per cent. The No. 8 mine of the Robert Gage Coal Co., producing 1000 tons a day, is closed. The Uncle Henry mine, owned by the Consolidated Coal Co., and practically every other mine in the Saginaw district, shut down last Wednesday. W. K. Prudden, state fuel administrator, has been asked to take the matter up with the Federal Railroad Administration. Unless a settlement is speedily attained it is feared the trouble will extend to all mines of the Saginaw valley.

Cleveland, Ohio—Ohio's production of coal in 1917 was 41,677,986 tons, an increase of 5,392,500 tons over 1916, according to statistics just compiled and announced by the Ohio Industrial Commission at Columbus. In the year the number of mines increased from 853 to 1295. Twenty-six of the thirty counties in which coal is mined increased their output last year. Four reported decreased production. Gallia, Perry, Scioto, Vinton and Washington Counties more than doubled their tonnage. The four reporting losses were Guernsey, Monroe, Summit and Wayne. In total tonnage in 1917 Belmont County led with 11,156,626 tons. Athens was second with 6,313,619, Jefferson third with 5,742,240, and Guernsey fourth with 4,024,265 tons.

Louisville, Ky.—Indications are that an agreement will shortly be reached between the Government and R. C. Tway, head of the Tway Coal Co. and the James Coal Co., whereby the case to be heard by the October term of the Federal Grand Jury may be dropped. Tway got in trouble with the Fuel Administration for overcharging and violations of regulations. Expert accountants who have just completed listing overcharges during the period from October, 1917, to March 1, 1918, found overcharges of $13,855.23. In many of the cases it will be impossible to pay the overcharges to the persons overcharged, and it is planned to hand this fund over to the Red Cross. It is believed that in consideration of the refunding of this money and payment of a fine into Federal Court the prosecution will be dropped.

New York, N. Y.—Thomas W. Russell, Fuel Administrator for Connecticut, has issued an order permitting wholesale dealers as defined by Rule 24 of the Rules and Regulations of the United States Fuel Administration to add to the purchase price of any bituminous coal shipped by water to that state a charge or commission of 35c. per net ton when the coal comes from the ports of New Jersey or New York, and 23c. per net ton when shipped from the ports of any other state. On shipments of anthracite an additional charge of 25c. per net ton is allowed. The order provides that the charge or commission shall include any purchasing or selling agent's commission heretofore authorized, and that the combined charges or commissions of any number of wholesalers or jobbers who act in the purchase of a given shipment or shipments shall not exceed the maximum charge or commission allowed for one wholesaler.

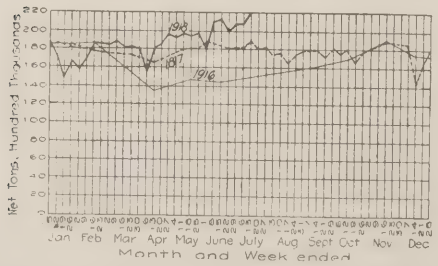
MARKET DEPARTMENT

Weekly Review

All Production Records Broken in Bituminous Regions—Anthracite Shipments Increase—Necessity of Conserving Fuel Still Remains—Transportation Facilities Unparalleled—Labor Still a Problem—Market More Hopeful

PRODUCTION records in the bituminous fields are being smashed. Coupled with the cheering news of the victories of our boys and the allies at the Marne, the successful onslaught on the storehouse of Mother Nature by the mining forces at home furnishes cause for a new song of jubilation. Every soft-coal region is reporting greater output than ever before. For the week ended July 13 the total of bituminous coal shipped from the mines amounted to 13,243,000 net tons, which is more than a million tons above the average weekly requirements set by the Fuel Administration as necessary to meet essential demands. The average weekly production of soft coal from April 1 to date, however, is estimated at 11,568,000 net tons. Therefore, to make up the total deficit of 9,615,000 net tons which now exists it will be necessary to have approximately ten more weeks of production equivalent to that of the week ended July 13, or an output of 12,472,000 net tons during each of the 37 weeks remaining in the coal year, which ends Mar. 31, 1919. During the week under review shipments of anthracite amounted to 42,331 cars, which shows a slight improvement over the forwardings of recent weeks.

In spite of the large tonnage of bituminous, the supply continues too light to permit of the creation of adequate reserve stocks against the time when bad weather will interfere with the expeditious movement of cars. The requirements of manufacturing plants have been vastly increased by the magnitude of the work they are doing for the Government, and the importance of obtaining shipments substantially in excess of current needs cannot be too strongly emphasized. The efforts of the Fuel Administration, operators and miners to increase production must therefore be supplemented by the elimination of every wasteful or unnecessary use of coal.



The railroads are making increasing demands for fuel, and nothing is heard of car shortage in any direction. In fact, transportation has caught up with output in a way that is really astonishing. The labor difficulties, however, multiply rather than diminish. There are restrictions now on the movement of labor from one section to another, and already there are interesting results in the coal industry, particularly in the Pocahontas and New River districts.

Developments during the past week have given the market a hopeful aspect, and consumers are beginning to believe that perhaps after all the situation may not turn out to be near so bad as was feared.

COAL PRODUCTION

A record-breaking production of bituminous coal marked the week of July 13. The output (including lignite and coal made into coke) is estimated at 13,243,000 tons, an increase over the week of July 6 (five working days) of 2,987,000 net tons, or 29 per cent., and over the current week of last year of 1,479,000 net tons, or 12.5 per cent. The average production per working day is estimated at 2,207,000 net tons as against 2,051,000 net tons during the week of July 6, or an increase of 7.6 per cent.; and as compared with the average production per working day of 1,961,000 net tons during the week of July 13, 1917.

The output during the current week of 13,243,000 net tons is approximately 1,031,000 net tons, or 8 per cent. above the average weekly requirements of 12,211,500

net tons established by the United States Fuel Administration. However, the average weekly production for the coal year to date is estimated at 11,568,000 net tons or 5.3 per cent. behind the weekly requirements. In order to make up the deficit for the coal year from Apr. 1 to date of 6,643,000 net tons per week, or 9,651,000 net tons, it will be necessary to have approximately ten more weeks of production equipalent to that of last week, or a production of 12,472,000 net tons during each of 37 remaining weeks in the coal year ended Mar. 30, 1919, a figure only twice attained—the week ended June 15 and the current week.

Reports from the carriers show increased shipments from all districts during the week of July 13. The increase in shipments from central Pennsylvania amounted to 34 per cent., in western Pennsylvania 30 per cent., in Ohio 27 per cent., in the district including northeastern Kentucky, high-volatile of southwest Virgina and smokeless fields of West Virginia 36 per cent., Tennessee and Kentucky 26 per cent., the district including Illinois, Indiana and western Kentucky 30 per cent., the district including Iowa, Texas and Southwest States 26 per cent., and the district including the Rocky Mountain and Pacific Coast States 30 per cent.

Beehive Coke—Beehive coke production in the United States during the week ended July 13 is estimated at 671,000 net tons, an increase over the week preceding of 92,000 net tons, or 16 per cent., and an average production per working day of 112,000 net tons as against 97,000 net tons during the week of July 6. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week of July 13 at 394 000 net tons and operation of their plants at 77.2 per cent. of their present capacity. Out of the total losses of time of 22.8 per cent., 0.5 per cent. was attributed to car shortage, 18.8 per cent. to yard labor shortage, 0.5 per cent. to plant disability and 3.1 per cent. to all other causes.

Byproduct Coke—Byproduct coke plants during the week ended July 13 were operated at 89.8 per cent. of their present capacity, slightly lower than the ratio of 90.3 per cent. reported for the week ended July 6. Improved labor conditions during the week were offset by time lost in plant repairs and the cause of the slight decline for the week was not reported. Repairs to plants caused slightly increased losses in time in Illinois, Massachusetts and Ohio, while the operators in Minnesota and Pennsylvania failed to report the cause of the slightly increased losses, although in the latter state better labor conditions existed. Improvement in operating conditions in New York were due to repaired plants and in the district including Michigan, Missouri and Wisconsin to better supply of byproduct coal and repaired plants. Increased capacity in Pennsylvania during the week of July 13 is attributed to placing new ovens in operation by the Bethlehem Steel Co at Steelton and by the Carnegie Steel Co. at Clairton.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: June 22	June 29	July 6	July 13
Bituminous shipments, 123 roads.	212,849	219,625	180,090*	234,899†
Anthracite shipments, 9 roads...	41,170	41,641	31,493	42,331

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

American Wool and Cotton Reporter—The Government has by no means taken all of the machinery, although more or less irregularity exists in the condition of the different sellers. There has been quite a long period where the production available for civilian distribution has been approximately 50 per cent. of the available producing capacity. Few can estimate what the future may be, but the total supply of goods for the season's requirements, while undoubtedly less suitable than usual, might be in actual yardage not greatly inferior to what the market requires.

Bradstreet's—Government needs and war work dominate, and industry, despite rather more unsettlement in labor lines, is still at a very swift pace. Wholesale and jobbing trade at primary centers reflects some seasonal slowing down and is quiet in comparison with the speed in industry, but in the larger markets of the west, south, northwest and Pacific coast, the reports are that trade is large and demand eager for an ordinary dull period. Retail trade, notwithstanding a good number of midsummer sales, is quieter than for some weeks past, but even at that loses nothing in comparison with the volume of business doing at this date in other years.

Dry Goods Economist—The shortage of raw material continues acute in the woolen and worsted goods industry. In this connection it is interesting to note the latest order issued by the War Trade Board under date of July 12, which declares: (1) That all outstanding licenses for the importation of wool from Uruguay, Argentina and South Africa are revoked as to ocean shipments made from abroad after July 28; (2) that hereafter no licenses for the im-

portation of wools from the countries named will be issued for the remainder of the present calendar year, except to the Quartermaster General of the U. S. Army.

Marshall Field & Co.—Current wholesale distribution of dry goods has been in excess of the heavy shipments of the corresponding week in 1917. The majority of our general line salesmen have been in the house during the past week. Road sales for immediate and future delivery from those remaining on the road have been better than they were last year. Customers have been in the market in greater numbers. Collections for the week show a satisfactory increase over those of the same week a year ago.

Atlantic Seaboard

BOSTON

Developments the past week give the market a hopeful aspect. Improvement at Hampton Roads due to emergency action which cannot be kept up. More and more difficulty over getting full quota from Pocahontas and New River districts. Production section of the Fuel Administration begins to show grasp of the situation. Apparently transportation has caught up with output in every direction. Remarkable fact that not one coal embargo has been in effect on New England roads since Apr. 1. Movement all-rail shows steady improvement. Railroad reserves also show an upward trend. Box cars being sent forward on direct order of the fuel authorities. Anthracite receipts all-rail continue in good volume. Retail advance general because of freight increase.

Bituminous—New England has always been responsive to improved market conditions, and this season is no exception. Somewhat increased receipts all-rail, better loading at the Virginia terminals, and signs here and there of accumulating stocks of 30 to 60 days are enough of themselves to make buyers less pessimistic. Of course, such improved conditions will have to be maintained over several weeks, or even months, before this territory will be in position to slacken its effort to get coal, but the moral effect is good and fly-by-night traders are doing less business on irregular propositions than has hitherto been the case. Reports that production has lately improved have also had their effect on buyers, and just now there is a period, probably a brief period, when consumers are saying that perhaps after all things may not turn out to be so bad as feared. Doubtless it is all a part of the general hopefulness that is in the air just now.

Bottoms at Hampton Roads have met with better dispatch the past week. Steamers that were thought certain to be detained several days were loaded with a fair degree of promptness. By the trade, however, it is realized that it was only through the strong arm of the Government that this was accomplished. First a special order was issued to send 200 cars daily from high-volatile districts out of shipments that would ordinarily move west, and later, when it was seen that the 10,000 tons or so a day would not be enough, a general embargo was declared against all westbound movement, thereby throwing a large extra volume to tide. Even byproduct plants in western territory were not excepted, and just that one fact will make it plain the quantity of coal now moving east will have to be replaced. It is therefore almost inevitable that delay at Hampton Roads will follow. Steamers will be available in increasing numbers, and certainly the outlook is not favorable today for anything like budget requirements for New England.

Difficulties in the smokeless region multiply rather than diminish. For a time there was a feeling that labor shortages would be made up with less trouble than in other fields, because miners would be attracted to thick-seam districts from fields where mining is more difficult. The operation of the new system of state directors of labor is affecting this, however. There are restrictions now on the movement of labor from one section to another, and already there are interesting results in the coal industry. The Pocahontas and New River districts are therefore chiefly dependent upon the usual labor supply, and under present conditions it is inadequate. The increased output of coke is another important factor, those in charge of coke production having seen to it price was made attractive. The railroads that serve these districts are also making increasing drafts for fuel, and when to all these other demands is added the enormously increased requirements of Government service, not to mention the tremendous powder plants now in process, it will be seen how slim a chance New England has of getting its water coal in sufficient volume, the largest part of which is supplied via the Hampton Roads piers.

The remarkable thing in New England is the fact that not one coal embargo has been in force on the New England railroads since Apr. 1. Indeed, it has been freely stated by the railroads themselves that at least 200 cars more per day can be handled through the gateways than are now coming through. The receipts of bituminous are increasing, but slowly thus far. For the first 16 days of July the average daily movement through the New England gateways for New England destinations was 611 cars of commercial bituminous and 151 cars railway fuel, a total of 762 cars. It is rumored that the current week will show shipments from the central Pennsylvania district alone of 4000 cars, but there is little hope of the movement reaching the 4500 figure that was set early in June to make up deficiencies during April and May. It is evident that the statistical section at Washington set too high a mark for the Altoona district in the first place. If now the gas coal region can be relieved of the heavy railroad fuel requisitions made upon it especially for the low sulphur grades, another gain could be registered.

The New England railroads are beginning at last to show materially larger stocks than during June. Thus far most of the accumulation has been built up from water-borne shipments, but beginning the current week, from shipments already started from the mines, there should be a considerable gain in receipts all-rail. The diversion of 40 cars daily from less essential industries to help the Boston & Maine railroad is still in effect and will hardly be canceled until the reserve of that road has reached a much higher figure than at present.

Apparently the Fuel Administration in some of the Pennsylvania districts at least is looking upon box car shipments, particularly from wagon-loading mines, as free coal, and it is quite likely most of the box cars forwarded will be handled in this way. It is common knowledge that many abuses in price, etc., have crept into box-car transactions, and doubtless this present program is an effort to straighten out certain of the shippers. Certainly New England consumers will take all the box cars that are sent, although there is a little anxiety here and there as to quality. None the less orders are being filed through the district representatives and for the present a considerable movement is looked for.

The inspection force attached to the office of the Altoona district representative is doing some effective work. When a car is rejected by an eastern railroad or by inspectors working under the Tidewater Coal Exchange the case is reported back and thorough investigation follows. In some instances cars have been ordered withheld from certain mines until the operators carry out directions that their coal be properly prepared before being sent forward.

Anthracite—All-rail receipts of domestic sizes for the first 16 days of July show an average of 514 cars. On July 14 the movement rose to 837 cars, a gratifying figure. Steam sizes maintain what has been a fairly steady movement, this month thus far showing 175 cars as a daily average, although the percentage has dropped from 30 per cent. to 25 per cent. By water there is no material change. The movement of barges is still slow on account of the lack of power. More coal could be loaded if bottoms could be moved more promptly. To a surprising extent owners of barges from New York are disinclined to send them east of Providence, and today there is a marked shortage of bottoms for New Bedford and for Boston, even through the canal.

The Boston retail price was advanced on July 18 from $10.25 to $11 for broken, egg, stove and chestnut. This is an advance of 75c. a net ton, and covers shovel delivery. Where coal has to be carried 40c. extra is charged, as against the former charge of 25c. for basketing. Another trade paper recently stated this advance much more than covered the increase in railroad tolls that made the advance necessary. This statement, however, takes no account of the fact that most of the Boston retailers receive coal by water and that on coal by barge from Philadelphia the increased charge is something like 83c.

NEW YORK

Receipts must increase rapidly to prevent serious shortage here. Efforts for wage increase interest producers. Dumpings at local docks show slight increase. Shipments on city order of 300,000 tons to begin Aug. 1. Bituminous situation quiet. No free coals to be had and consumers storing little. Unnecessary illumination prohibited. Miners dissatisfied.

Anthracite—A rapid improvement in receipts of anthracite must be made if this city is to escape a near-coal famine next winter, according to some of the trade, while others look for a comparatively easy situation, expecting that the Anthracite Committee of the Fuel Administration will soon cancel their order diverting additional tonnages into New England. They expect that some similar order may be issued regarding shipments to this city, and it will be necessary, many claim, to keep homes warm. Of the five boroughs comprising Greater New York it is admitted that Manhattan is in better shape than any of the others. This is due to the small increase in additional building construction, while the larger increase in population in the other boroughs is resulting in increased need for fuel.

Producers and shippers here are watching with interest the efforts of the mine workers to reopen the wage agreement of last November, although it was stipulated that it was to remain in force until 1920. A committee of mine workers has been appointed to confer with the operators for that purpose, the miners setting forth that living conditions have changed since the signing of the agreement.

No successor to Mr. Wiggin as State Fuel Administrator has yet been announced, although promises are reported to have come from Washington that the appointment was to have been made "within a few days." The report that New York State is to be divided into two districts continues to persist.

The Lehigh Valley Coal Sales Co. has advanced its mine prices for buckwheat and barley 20 and 30c. respectively, placing them on a level with other companies shipping to the lower ports, namely $5.15 and $4.15 f. o. b. docks.

Dumpings at the local tidewater docks for the seven days ended July 19 show 7375 cars of anthracite dumped, an increase of 50 cars as compared with the previous seven days.

With the exception of barley, there is a scarcity of all sizes. Some shippers offer barley only and invite buyers to include that size in their orders for the other coals. Other shippers have nothing to offer, their entire output being provided for.

Markets Commissioner Day has announced that he expects shipments on the 300,000-ton contract made with the DeJulio Coal Co., of 220 Broadway, to commence Aug. 1, at the rate of 1500 tons daily. This coal will be taken from two culm banks near Ashland, Penn., and is said to consist of a fine grade of stove, chestnut and pea sizes, mixed. The coal is to be delivered alongside piers in Manhattan at $6.55 per ton, and it is expected that local dealers will see that it is delivered from these points.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports, are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Pea	$5.20	$5.95
Egg	6.35	7.10	Buck	5.10	5.90
Stove	6.60	7.35	Rice	4.65	5.10
Chestnut	6.70	7.45	Barley	4.15	4.30
			Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The local situation shows no improvement. Coal is scarce, regular customers receiving just about sufficient to keep their plants going with hardly any surplus. Free coals are seldom heard of, although there is an urgent call. The order of the local Fuel Administration prohibiting unnecessary illumination of show cases and windows between sunrise and sunset is not expected to result in much saving of fuel here, but is believed to be the forerunner of other and more drastic orders soon to be issued.

The decision of the Interstate Commerce Commission regarding the placing of demurrage charges on boats after they have been registered at the loading ports and not loaded because of frozen coal due to weather conditions is being awaited by the trade. This is an important matter to coal shippers, and if decided in their favor will result in considerable saving to them.

There were dumped at the local tidewater docks in the period July 13-19 inclusive, 7130 cars of bituminous, an increase of 41 cars over the preceding seven days. Car supply shows some improvement and operators are kept busy at some of the mines to get them loaded.

The New England situation continues to be responsible for heavy shipments from this market. There is a good movement of bunker fuels and the surplus is not large.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-run, prepared or slack.....	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-mine.....	3.08	5.23
Prepared.....	3.36	5.51
Slack.....	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite little changed. Slight improvement in spots. Promise of better deliveries soon encourages dealers. New conservation rules. List of restricted uses growing. School coal being arranged for. Miners show signs of uneasiness. Steam coals extremely active. Bituminous improvement continues. Car supply good. Wagon mines must prepare coal.

Anthracite—It is believed that some real progress has been made this week, at least in one section of the city that was most troublesome last winter and would undoubtedly need more attention this year. In the southwestern section of the city, owing to the proximity to the immense Hog Island shipbuilding plant, the increase in population has been extremely heavy. Coal can be consigned to yards from which deliveries can be made into this territory over five different branches of railroads.

New rules and regulations regarding the conservation of fuel are being made almost daily and it is certain that dealers are having trouble trying to obey the laws governing their business. The latest ruling compels them to attach a 2c. fuel stamp when filling orders for No. 1 buckwheat coal for schools, churches, hospitals, hotels, office buildings, stores, apartment houses, theaters, banks, garages, greenhouses, restaurants or saloons. It will be remembered that formerly the dealer was exempt from this tax on all No. 1 buckwheat deliveries, except those for purely domestic use, and this new expense to the dealer is not as trivial as it first appears. All this has been occasioned by the fact that with the placing of buckwheat in the exempted class as a domestic fuel it makes it necessary for these orders to pass through the fuel committee's auditing office for checking, with the consequent adding of the 2c. per ton tax.

Certain dealers have been notified by the Board of Education that they have been awarded the contract for hauling coal to the schools. In many instances these are the same dealers who made the deliveries in 1916, as it is the understanding the fuel administration is arranging for the same shippers to furnish the coal this year. Pending the arrangement of final details as to the source of supply, no definite announcement has as yet been given out. It is believed that the delay is principally due to the apportioning of the 30 per cent. buckwheat which the schools have agreed to take.

It now develops that no official authority for dumping coal on the pavements and not carrying it in the bins of the customer has ever been granted to the retail men. While the practice has been adopted to a limited extent, Mr. Lewis is now considering allowing the dealers to make an increased charge for this work, and if the customer objects to this he then has the option of doing it himself.

There continue to be some complaints of certain shippers who are not strictly abiding by the allotment as fixed by the distribution committee, and this in spite of the very pointed letter sent out recently. The dealers in certain sections point out instances of retailers not in business in 1916, who are receiving particularly heavy shipments. It is believed, however, that the entire matter will be remedied and that such instances have been due to a misunderstanding as to the exact meaning of the regulations.

It is becoming pretty generally known among the trade that the production of family sizes is not up to the record of last year, and it is this that has made them so uneasy of late. The best informed men in the trade cannot but admit that the city is bound to witness some strenuous times next winter unless some method is found whereby production can be immediately increased. In the matter of draft exemption it now appears that the army authorities claim that the local boards have had power all along to exempt mining men, but this does not satisfy those who see the serious aspect of the diminishing labor supply at the mines. It is still asserted that a general order should be issued prohibiting any man who has been engaged in work at the mines from enlisting in any branch of the service. Even in the cases where boards have exempted men they seem to have felt a stigma attached to it and have gone off and enlisted in other branches.

There also seems to be a growing restlessness among the miners in the region. Last week the question of increased wages cropped up for the first time in a semi-official way, and now this week there was a local strike at a colliery, where several hundred men went out claiming that they should be paid better wages for certain classes of work. It is the private opinion of many well-informed coal men that a definite demand for increased wages will be made before the first of the year, as the men claim to be strongly affected by the recent heavy increase in the cost of commodities of all kinds.

Steam coals continue in the extreme demand that has prevailed for weeks past, with the exception of culm locally. From outlying points the demand for this grade is actually becoming heavier each day, particularly from the New England region. The general price continues to be $1.25.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken.....	$4.90	$6.25	Buckwheat..	$3.40	$4.45
Egg.....	4.50	5.85	Rice.....	2.90	3.80
Stove.....	4.75	6.10	Boiler.....	2.70	3.70
Nut.....	4.85	6.20	Barley.....	2.40	3.30
Pea.....	3.45	4.70	Culm.....	1.25	2.15

Bituminous—The good car supply in evidence since the early part of the month continues and most mines report as many cars on hand as they are able to load. Good shipments are also coming into the city, and fair progress is being made in storing coal, although it is felt that there could probably be a more equitable distribution, as there are some important plants that do not seem to be faring as they should.

The preferential shipments to New England are still in effect and all shippers are making efforts to maintain their quota, although the feeling continues that they should be allowed more leeway in the distribution. The rumored order denying cars to the wagon mines does not seem to have been given the official stamp as yet. It is a fact, though, that several mines of this kind have been shut down for turning out an inferior product and will not be allowed to resume shipping until they are in position to prepare the coal.

The brokers still continue to be able to get quite a little tonnage, the most of which is obtained, especially by the smaller houses, by keeping men permanently in the region to negotiate for the coal right at the mine.

In tide coal, due to some new arrangements for deliveries from the pools, there is a prompter movement of fuel and quite a heavy volume of business is moving, both in bunker and tide shipments.

At this time there is a movement on foot among the soft coal men to effect a more stable arrangement with the fuel authorities when coal is seized and delivered to new consignees by their direction. Of course, this is being done only in the rarest cases now, but was quite common last winter. The shippers are asking that the authorities see that they are given advance notice in every instance of this kind, so that they can keep their records from becoming confused and at the same time make the necessary credit arrangement.

Lake Markets

PITTSBURGH

Distributing problem somewhat simplified. Consumers hope to receive stocks later. Market transactions reduced.

The matter of distributing Pittsburgh district coal has been somewhat simplified by the requirement that only current wants of consumers may be supplied, in the interest of forcing lake shipments to the maximum to make up for the required diversion to the Navy of West Virginia and Kentucky coal. No estimates are yet made as to the quantity of lake coal that will be shipped from the district this month, but hopes are entertained that the quota originally assigned for the month, 1,300,000 tons, will be greatly exceeded.

A slight improvement in labor performance is noted, due to the individual efforts of the coal operators as well as to the efforts of the Shipping Board, but there remains much to be desired in this direction.

Coal consumers are not getting all the coal they would like to receive by any means, but those engaged in the more essential lines of war work are well supplied through the efforts of the distributing agency. As to stocks to tide over the winter, consumers feel that if after the middle of October they receive extra coal at the rate at which it is to be shipped in the lake trade from now until then, minus the additional amount that will be required for domestic purposes, they may enter the period of bad weather in fairly safe position. River coal shipments are rather heavy and it is only river coal that local dealers can put into stock.

Scarcely any coal is being sold in the open market, except for such transactions as are dictated by the coal distributor. Brokers are doing less business than formerly, as it is only when their customers have a preferred claim for coal that the business is sanctioned. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at line, Pittsburgh district, brokers being allowed to charge customers up to 15c. commission in addition.

TORONTO

Coal situation increasingly serious. Dealers months behind in deliveries and refuse new orders. Fair supplies of soft coal on hand. Fuel controller issues reassuring statement. Attitude of United States appreciated.

The coal situation continues to grow more serious. While deliveries of anthracite in Toronto have been so far fully equal in volume to those of last year the dealers are months behind in filling orders, and generally refuse to make sales even for future delivery. Very few new orders are being taken and great apprehension is entertained that conditions next winter will be considerably worse than those experienced last season. There is a fair supply of bituminous on hand and many consumers unable to obtain hard coal are purchasing soft coal for domestic use. R. C. Harris, Fuel Controller for Ontario, while admitting that the supply is uncertain, does not consider that a serious coal famine is probable. He says: "The Fuel Administration of Canada is alive to the situation in a greater degree than any one else in the Dominion and is straining every effort to cope with the situation." H. A. Harrington, secretary of the coal section of the Retail Merchants' Association, has just returned from the United States, where he has arranged for a further supply of coal. He expresses strong appreciation of the generous treatment Canada is receiving from the United States, but emphasized the fact that strict fuel conservation is an absolute necessity.

Quotations (largely nominal under the circumstances) for best grades per short ton are as follows: Retail anthracite, egg, stove, nut and grate, $11; pea, $10; bituminous steam, $9; slack, $8; domestic lump, $10.50; cannel, $13. Wholesale f.o.b. cars at destination, three-quarter lump, unprepared, $6.41; prepared, $6.61; slack, $5.48.

BUFFALO

Coal not as plenty as it was, especially anthracite. Fuel authorities are watching the situation closely. Extreme caution is the plan. All demand is heavy.

Bituminous—The demand for all sorts of coal is heavy, but the real situation cannot be made out from that. Consumers are taking all the coal they can get, if they can take care of it. It is believed that considerably more bituminous is in the hands of consumers than there was a year ago, but that is not the case with anthracite.

The situation is such that the operators are afraid of priority orders that will keep them from filling their contracts and cause distress in one place where it is relieved in another. This feeling is heightened by the orders coming out every few days, cutting off the supply to this or that industry or institution that is not considered essential. The breweries and the greenhouses are to have but a half supply, and the country clubs must burn wood or peat.

The prices of bituminous remain at $4.65 for thin-vein Allegheny Valley, all sizes, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine-run and slack, $6.15 for cannel and $5.85 for smithing, all per net ton, f.o.b. Buffalo, with jobber's profit added.

Anthracite—The situation grows more complicated. The county fuel administration is demanding monthly reports from all distributors of the amount of coal delivered, to whom and the amount asked by the consumer. At the middle of the month a circular was sent out to trestle owners or others who supply retailers, giving the names of 84 concerns who had not complied

with the regulations. The claim is mostly that no monthly report had been made. In some cases the consumer was given the full amount asked for, instead of the two-thirds allowed. These dealers will get no more coal till they square themselves with the fuel authorities.

The retailers of anthracite generally complain that their orders increase while the supply falls off, but the authorities say that when the allotment that has been asked for is granted (900,000 tons for the county) a better supply will be obtained. Just now the lack of a state fuel administrator is holding the local trade up, as everything has to be referred to Washington direct.

In the lake trade the supply is also running down. It was found that the Canadian districts had been getting more than their share by rail, and now the lake shipments to Canadian ports are made very small. There is a general falling off, the amount for the week being only 80,500 tons, of which 37,800 tons cleared for Duluth or Superior, 25,200 tons for Milwaukee, 8000 tons for Sheboygan, 7800 tons for Chicago and 1700 tons for Depere.

With coal so scarce many vessels are obliged to go out light and coal freight rates are easy at $1 for Depere, 60@65c. for Chicago, 55c. for Milwaukee, 50c. for Sheboygan and 48c. for Duluth.

CLEVELAND

Movement of bituminous is all that can be expected with virtually a 100 per cent. car supply at the mines, but this is not sufficing to meet present needs, especially of the Northwest. With half of July gone and the month's lake quota unfilled so far by nearly 500,000 tons, operators are agreed that Fuel Administration officials must provide adequate labor supply and insist that no coal be stored at present.

Bituminous—Operators with mines in the Pittsburgh vein district of southern Ohio report every condition highly satisfactory except labor. Car supply continues at approximately 100 per cent. With what labor is on hand, operations are being rushed at a point not equaled so far this coal year. But a 100 per cent. car supply today does not mean a 100 per cent. output when compared with two years ago, operators claim. Instead, with men going into the army and more steady employment in the cities, a 100 per cent. car supply now means only, on an average, 75 to 80 per cent. of maximum output two years ago. One operator, who with a 100 per cent. car supply used to get out 60,000 tons of bituminous a month from one mine, now is getting only 34,000 to 36,000 tons under comparative circumstances. Less stocking of coal at industrial plants is apparent; some seems to be done despite orders to the contrary. The latest report of the Pittsburgh Vein Operators' Association for Ohio, for the week ended July 19, gives shipments to railroads as 1678 cars; to the Great Lakes, 2894; to Ohio, 1463; to Michigan and Indiana, 251, and Canada, 101. These shipments were made as follows: On the Baltimore & Ohio, 2914 cars; Pennsylvania, 1501; Wheeling & Lake Erie, 1706, and on the New York Central, 138.

Lake Trade—At a meeting of the coal committee of the Coal and Ore Exchange, which is handling the pool of Great Lakes vessel, coal and iron ore interests this season, it was decided to send Federal Fuel Administrator Garfield a letter urging him to help speed shipments of bituminous up the Great Lakes. The committee is of the opinion that if stocking of coal is absolutely prohibited until the lake season is over, and some of the industries that have large storage piles are compelled to dig into them now instead of diverting coal that should be going up the lakes, that the Northwest's requirements of 28,000,000 tons will be met, and a 100 per cent. supply next winter will afford coal for all when the need for it arises. Though fuel administration officials at Washington are reported to be banking on July proving a 5,000,000-ton month—it is scheduled as a 4,900,000-ton one—the first half of July saw only 1,791,320 tons shipped, according to the Coal and Ore Exchange's figures. This is about 500,000 tons behind. Lake carriers now are getting more cargoes than in the early part of the month, but many are going up light. Shipments in the week ended July 13 are known, by corrected figures, to have been 821,640 tons. For the week ended July 20 the first figures compiled give the movement as 19,611 cars.

DETROIT

Shipments of steam and domestic coal continue too light to permit creating adequate reserves. Anthracite supply is short. Lake shipments improve.

Bituminous—Although requirements of many of Detroit's manufacturing plants are increased by the magnitude of the work which they are doing for the Government, the supply of steam coal made available in the local market continues less than the amount regarded as adequate to supply needs in previous years. While there is enough coal arriving to provide for present use, jobbers say the supply is too small to permit a satisfactory building up of reserves, which should now be under way, and therefore is insufficient. The importance of obtaining shipments substantially in excess of current needs is emphasized as necessary to assure continued operation of plants turning out military supplies and other Government work, in case developments later in the season diminish receipts. The present supply affords little diversity in selection as most of the shipments consist of mine-run. Some slack is included, but jobbers complain that domestic stock is deficient in amount. The situation and outlook occasion much anxiety. Unless receipts are largely increased at an early date, it is feared hardship and suffering will be unavoidable for household consumers unsupplied with fuel.

Anthracite—Detroit's supply of anthracite is not increasing. With the season half gone, distribution has been held back by lack of coal and there is still no movement of sufficient size to enable the retailers to get delivery under way.

Lake Trade—There is a freer movement of bituminous coal to lake loading docks and shipments by boat during the week attained a larger volume than usual. The total, however, failed to attain the amount necessary to carry out the schedule for the month. The vessel capacity available for loading was greater than the supply of cargoes. Many boats went up light.

COLUMBUS

The coal trade in Ohio continues active in every respect. There is a strong demand for steam, lake and domestic tonnage. Production shows a light gain.

Strength is the chief feature of the coal trade in Ohio. All departments of the industry have been active and buying is on a brisk scale. Steam users, as well as retailers, are in the market for a large tonnage, while lake shippers are straining every point to move a large tonnage to the Northwest. On the whole the tone is satisfactory and special efforts are being made to speed production.

Domestic trade is one of the strongest points at this time. Dealers are in the market for a larger tonnage to replace depleted stocks caused by heavy retail buying. Most of the orders are for immediate delivery. Householders are buying actively, as they believe a fuel shortage will occur during the coming winter. Retail prices are firm at the levels which have prevailed for several weeks, but when freight matters are adjusted still higher prices will be announced. Pocahontas is a scarce article in the Columbus market. Some West Virginia splints are being received, but the main fuel supply comes from the Hocking Valley and Crooksville districts.

A large amount of screenings is reaching the market because of the heavy lake business in lump. This is relieving the steam situation to a certain extent, but on the whole the steam demand is firm. Consumers, especially those using a large tonnage, are adopting every means possible to increase their storage. The smaller steam users are following the example of the larger consumers and are also trying to secure a surplus. Railroad consumption continues large. The threshing rush is now about over, and a large tonnage was required for that purpose. Freight rate advances are expected to have a considerable influence on the steam trade.

Production is fairly good in most of the mining districts of the state. Labor shortage is reported from every field, but most especially from eastern Ohio and Massillon. The Hocking Valley produced about 85 per cent. of normal during the past week, and the same percentage is reported from Pomeroy Bend. Crooksville and Cambridge had about 75 per cent., while eastern Ohio is lagging behind with about 65 per cent. The last named field is hampered both by car shortage and labor shortage.

The lake trade is active, and the Fuel Administration is stimulating the movement as much as possible. All fields are short of pre-season estimates, and shippers are urged to move coal as rapidly as they can. Loadings at the docks continue to show up well, despite some hindrances.

LOUISVILLE

Demand for all grades of coal continues strong, with dealers considerably behind on deliveries and no surplus stocks accumulating. Somewhat better supply of coal moving in.

There has been an appreciable improvement in the movement of coal from the east and west Kentucky mining districts due to improved labor conditions and a fair car supply. The combined effects of the work or fight order, and the fact that agricultural labor is not in such big demand during the present growing season, has resulted in the mines being much better supplied than for some time past. However, in some sections, especially western Kentucky, drafts have played havoc with labor.

The St. Bernard Mining Co., operating eleven mines in the Earlington, Ky., district, has been forced to close one mine, and the balance are averaging 60 per cent. of their capacity. Over 100 men were sent from the district to the army camps on July 19.

Effects of the light production are shown in the July stocks in the four retail yards of the St. Bernard Coal Co., at Louisville, two yards having no lump coal, and the other two having four cars between them. About 15 cars of steam coal, 10 of nut and slack and four of Straight Creek gives the company a stock of slightly more than 30 cars at a season when the yards should be jammed to overflowing with surplus stock.

Coke

CONNELLSVILLE

Small gains in production. Byproduct oven building proceeds slowly. Blast furnace output unsatisfactoy. Reclassification of screened coke.

The coke situation is without important incident. Production in the region seems to be increasing, but the average gain from week to week is almost infinitesimal. The byproduct ovens are probably doing as well as could be expected, averaging an output of about 90 per cent. of rated capacity, a percentage which apparently cannot be materially exceeded. Construction of the new byproduct ovens is proceeding very slowly. At the Clairton plant of the Carnegie Steel Co., for instance, where a start was made by drawing some coke from the first battery of 128 ovens on June 25, it was hoped that the other four batteries might be completed by about the end of August; but the latest estimate is that it may be Dec. 1 before the whole 640 ovens are in operation, and completion of the second five batteries is set correspondingly farther in the future. A slight evidence of easier conditions as to coke supply is the decision of the company to blow in this week its Zanesville furnace, a small detached stack operated only when iron is scarce and coke in fairly good supply. It uses Pocahontas coke.

Generally speaking, the blast furnaces do not appear to be particularly short of coke, and yet their pig-iron output is far from what it should be considering the number of stacks in blast and the outjut per furnace that was attained in 1916.

W. L. Byers, district representative of the Fuel Administration, interprets the regulations of the Fuel Administration announced July 8 to mean that coke that is improperly screened may be sold at $4.50 if it is fairly satisfactory, otherwise it must be classed purely as "breeze" and therefore sold at not above $3, a price it would hardly bring in the market, perhaps. The new regulations make the $7.30 price for crushed coke apply to coke over ¾-in. instead of over 1-in. Clean screenings under ¾-in. are limited to $5, or $1 under furnace coke. Breeze is set at a $3 limit, or one-half the price of furnace coke, and includes unassorted coke and material left after removal of prepared sizes.

The market remains narrow, practically no furnace coke being openly offered, although some is picked up by furnace representatives in the region from time to time. There is a fair volume of foundry coke available, and sometimes operators are willing to pay brokers a small commission for disposing of it. The market is quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; prepared sizes of clean dry screened coke under ¾-in., $5; breeze, $3, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended July 13 at 353,470 tons, an increase of 3575 tons.

Buffalo—The demand for coke is good, and with more than 50,000 tons of iron ore coming in by lake every week the furnaces must be running as never before. Still the coke is seldom turned over to jobbers to sell in these days, the Government prices being paid to the ovens direct. These are $7 for foundry and $6 for furnace at the

ovens, with freight $2 from the ovens and no selling profit to add. Vessel owners are pleased with the ore trade, as there is less delay at the unloading docks than common, so that they can make quick trips. The supply promises to last the season through.

Middle Western

GENERAL REVIEW

Feeling of optimism among Middle West coal operators. Labor situation arouses apprehension. Car supply unusually good.

There is at present a decided spirit of optimism among the coal operators of the Middle Western district. This is all the more noticeable, because for the past three months the outlook, seen through the eyes of the average operator, has been anything but bright. This condition has been brought about by a number of facts, chief among which is the labor situation. The establishment of a Federal Employment Bureau to help the labor situation is being watched with keenest anticipation, and it is expected that very substantial assistance is to be rendered to the coal industry through this channel. This is the consensus of opinion of a number of the big operators.

Another bright spot is the probability of prohibition for the duration of the war. The operators have been in favor of this step for a long time, as it is a well known fact that alcohol has a very decided effect on coal production. The officers of the miners' unions are also for prohibition, both on the grounds of patriotism, as more coal is needed, and on the grounds of looking after the best interests of their own members. The percentage of accidents caused by drunkenness is appalling.

The car question for the past week has been unusual. Railroads like the C., B. & Q., the C. & N. W., the I. C. and others report nearly 100 per cent. supply of cars at their respective mines. Transportation difficulties at this time cut no material figure. Consumers report a rapid movement of coal from the mines to their factories.

CHICAGO

Market conditions undergo change. Easing of steam sizes. Rumor that Government is to place large order.

Market conditions have changed considerably during the past few days. There has been a slight weakening in the domestic market, as dealers are no longer satisfied with mere coal. They have a sufficient supply, either rolling to them or in their bins, to be more discriminating. Of course the demand for high grade and carefully prepared coals from southern Illinois, Indiana and the Springfield districts remains just as strong as ever, but the dealer is not tempted with 2-in. lump or mine-run as he was a week ago.

There has been a noticeable easing of all steam sizes, especially on screenings. Operators are offering freely a large tonnage from nearly all the producing districts. Some coal is selling below the Government price, but most of the better grade products are firm at "Government prices current at time of shipment."

There is a pretty well defined rumor out to the effect that the Government is about to place some large orders. The total will, in all probability, amount to 300,000 or 400,000 tons to be used at various camps and military depots in this territory. If this rumor materializes, a decided change in market conditions may be looked for at once, as the order will call for mine-run, and the tonnage is big enough to remove enough coal from both the steam and domestic market to strengthen any weakness that might develop.

Quotations in the Chicago market are as follows, per net ton, f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La-Salle, Bureau and Will
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40
Domestic lump	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40

MILWAUKEE

Report that breweries were to be denied coal of any nature after Jan. 1 causes commotion. New anthracite rates still held back. Cargoes arriving steadily.

With huge steamers filled to their decks with coal moving up the rivers daily, and with mountainous heaps of the fuel in constant sight from the several viaducts which span the river valleys, it is surprising that there is so much agitation and concern in Milwaukee over the prospective supply for next winter. This is due largely to the persistent campaign of alarm pursued by the state fuel bureau and councils of defense, in their efforts to stimulate the placing of orders by small consumers, and also to the fact that brewers and maltsters have been restricted in the use of bituminous coal and denied anthracite altogether. Anything affecting the breweries in Milwaukee is bound to receive the attention of the masses. Milwaukee is not so far behind in her coal supply that the shortage cannot be made up before the close of navigation if reasonable energy is employed at the sources of supply.

Anthracite continues to be delivered without knowledge as to cost. Those who claim to know say this is done to allow dealers on the outskirts of the city (who are selling anthracite received by rail at rates considerably above what the city schedule will be) to work off their stocks before the lower prices are announced. As these dealers helped the fuel situation by getting this coal, the fuel administration is not disposed to expose them to loss.

An ordinance which would permit coal dealers to dump coal in the streets in front of points of delivery and thus shirk the problem of putting it into bins was voted down by the common council of the city. There is no question but the policy of the fuel administration in forbidding full deliveries to be made at this time will greatly complicate the delivery problem during the winter, as two deliveries will now have to be made in a great many cases where formerly one sufficed.

Notwithstanding the coal stringency, there will be a great sufficiency of coke and gas for heating and cooking purposes. Both gas and coke producers are urged strongly by the Government to increase their facilities for making coke because of the need of coal byproducts in the making of high explosive shells. The Milwaukee Coke and Gas Co. and the Milwaukee Gas Light Co. are running to their highest point of production.

Cargo receipts since last week's report total 3000 tons of hard and 14,350 tons of soft coal, making 175,591 tons of hard and 1,108,707 tons of soft since the opening of navigation.

ST. LOUIS

A rather quiet market in a general way, with steam sizes heavy. Domestic demand shows some slight improvement. Equipment shortage rather acute. Labor problem serious in all districts. Carterville continues scarce. No outside shipments.

The local situation has been rather quiet on account of the car shortage, which has kept the market somewhat uniform—that is, a supply that about equaled the demand in domestic sizes, but with the steam sizes off. There still continues to be a fairly good demand for Carterville coal, and the supply coming in seems to diminish.

The labor shortage in this field is perhaps the most severe of any, for the demand for this grade of coal is greater than in any other two fields in southern Illinois. The operators are doing their very best to increase the tonnage, and as a rule the men are coöperating. The railroads continue to draw heavily from this field, and it is understood that they are going to insist that they get this coal in preference to others who have always used this in the past. Much similar conditions exist in the Duquoin field.

The Mt. Olive field continues the only stable district in the southern Illinois field. The labor supply is rather good, the car supply is fair, and the supply about equals the demand. The railroads continue to draw heavily on this section, but the domestic demand is being taken care of promptly.

The Standard district presents an entirely different phase. There is still at times to some extent an overproduction, but with the decreasing labor supply and car supply this is soon going to be a thing of the past. For the past few months there has been more coal produced than could be absorbed by the market to which this field was entitled to ship. Car supply has been unusually poor throughout the Standard field the past week and the movement of cars has dragged a little. Steam sizes continue to be heavy, especially screenings.

There is considerable railroad coal moving from this territory at the present time, nearly all mine-run, and this is going at a price of from $2 to $2.20, with here and there a report that some is being sold as high as the maximum price, but this is something unusual and cannot be verified. There is no outside coal coming in from the eastern fields and very little from Arkansas.

The new price on coke effective July 9 has caused the local market to be $10.10 f.o.b. ovens for gashouse and byproduct, and there is a shortage of both. The country demand for coal is good at the present time. Especially is this so in the South.

On the 16th and 17th Lieutenant Governor Wallace Crossley, Fuel Administrator for Missouri, had a conference with other administrators in Chicago relative to the allotment of different Illinois coals for Missouri and other states. It developed in the hearing that St. Louis got a total of 6146 cars of Illinois coal in the month of June for all purposes, and that the State of Missouri for the same month got 8908 cars. St. Louis got from the Williamson and Franklin County field for all purposes a total of 1785 cars, which is a respectable showing in comparison with the movement of some coals in the same periods in past years, and shows that St. Louis as a whole is storing coal and to a greater extent than is generally supposed. The prevailing market is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....
No. 3 nut	2.55@2.70	2.55@2.70	.....
No. 4 nut	2.55@2.70	2.55@2.70	.....
No. 5 nut	2.05@2.20	2.05@2.20	.....
2-in. scrgs	2.05@2.20	2.05@2.20	1.25@1.50
3-in. lump	.....	.....	2.25@2.40
2-in. lump	.....	.....	2.25@2.40
Steam egg	.....	.....	2.25@2.40
Mine run	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1	2.75@2.90	2.75@2.90	.....
No. 2	2.75@2.90	2.75@2.90	.....
No. 3	2.55@2.75	2.55@2.75	.....
No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

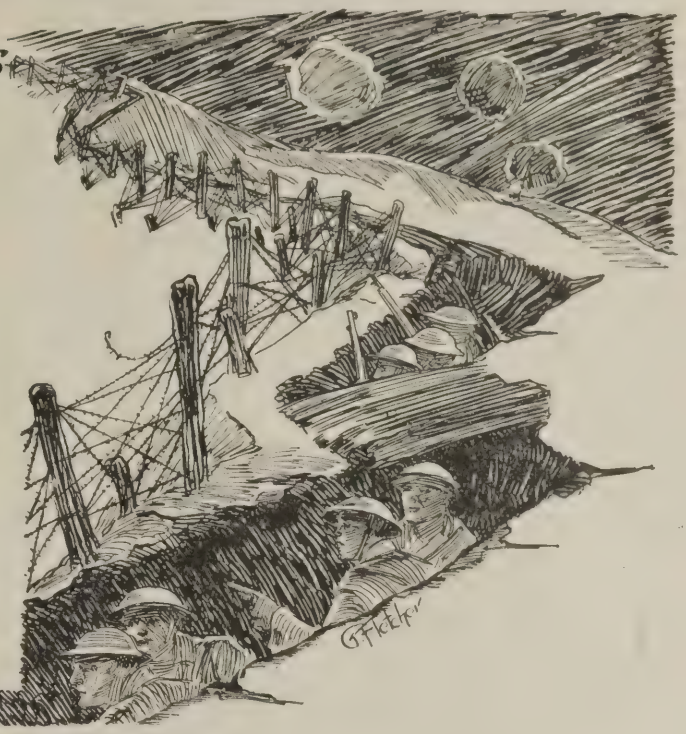
Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

General Statistics

BALTIMORE & OHIO

The following is a statement of the coal and coke tonnage moved over the Baltimore and Ohio system and affiliated lines during the month of April, 1918, as compared with the corresponding month of the previous year:

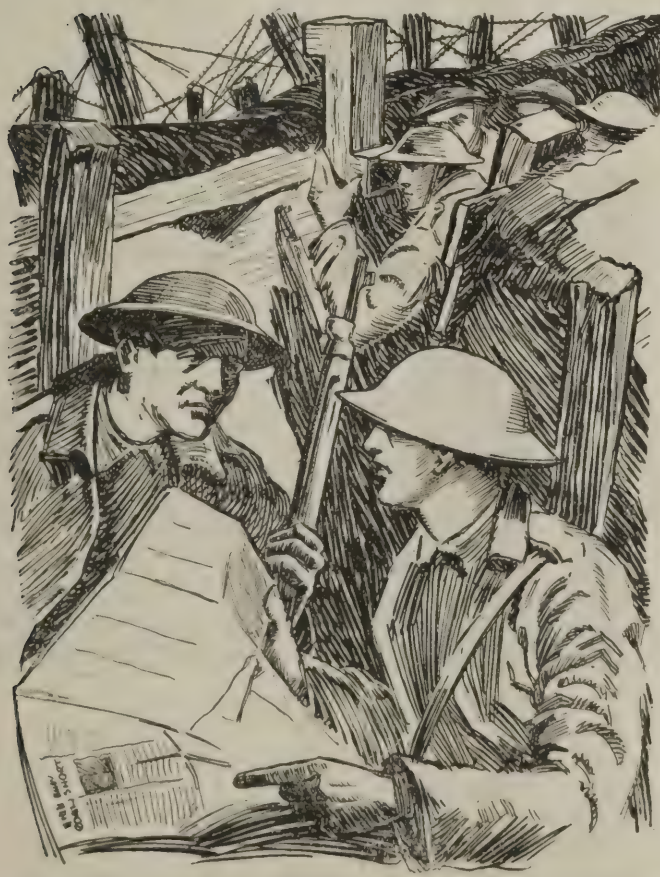
	Tons, 1918	Tons, 1917
Coal	3,600,539	2,861,603
Coke	319,236	309,823
Total	3,919,775	3,171,426



DUE to the fact that "Coal Age" has changed its day of issue from Saturday to Thursday, and also to the slowness of the mails, we have been compelled to omit from this issue the market reports from Baltimore, Cincinnati and Birmingham.

COAL AGE

Volume 14 — New York, August 1, 1918 — *Number* 5



A Voice from the Trenches

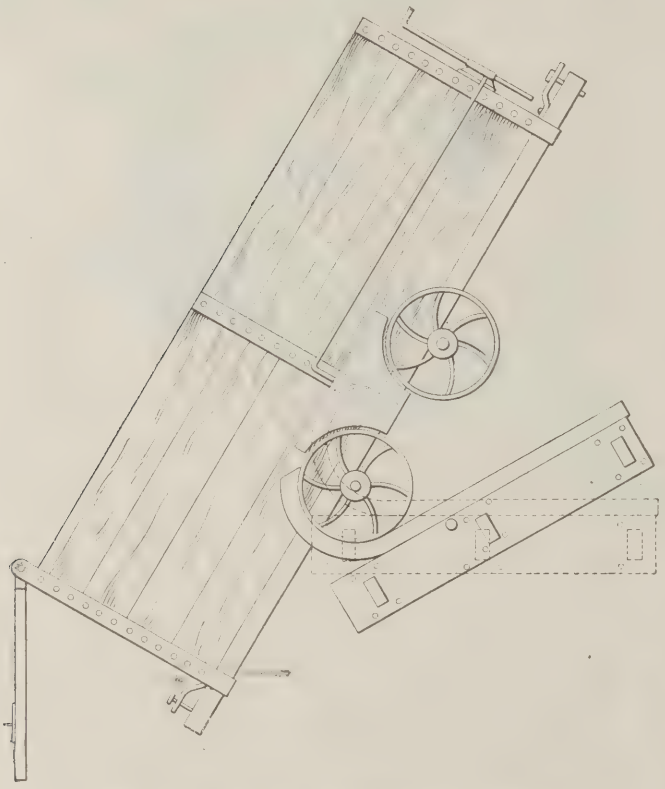
Written expressly for Coal Age
by Rufus T. Strohm

For the love of Mike, pal, looky here
At the things the papers say!
Them minin' chaps must be gettin' queer,
Or at least it seems that way;
For they work three hours, or mebby four,
At the bottom of the pit,
An' they've earned enough for a day, an' more,
So they grab their pails an' quit.

Well, what do you think of that, old scout!
Now, wouldn't it jar you, hey?
They're hardly in till they're up an' out,
But they call it a workin' day!
An' the country yells, for the notion grows
It'll freeze its ears an' beak,
Yet the miner's time card seldom shows
More than thirty hours a week.

By the great gran'dad of Jehoshaphat!
Just suppose that you an' me
Went about our work in a way like that—
Where the devil would we be?
Why, Fritz would come with his sneaky face
An' his shifty, piggy eye,
An' me an' you'd find a restin' place
Underneath the wavin' rye.

No, the job we've got don't start an' stop
With the strikin' of the clock,
For we're wide awake an' we up an' hop
Ev'ry time that the Boches knock;
An' the hours come, an' the hours go,
An' the sun swings round to sun,
But we keep right on, for we never know
Any rest till the fightin's done.



They've done good work, have the minin' guys
When they've had to meet the test,
An' I'd be the last to criticise
If they'd done their level best;
But to blow an' brag of their skill an' speed
Is a bloomin' bit of cheek,
For the war for freedom won't succeed
Workin' thirty hours a week!

IDEAS AND SUGGESTIONS

Finding the Dump Pivot

BY T. F. PRICE
San Antonio, Texas

The old style horn dump, as shown in the accompanying illustration, is still extensively used in some regions. It finds greatest application in slate dumping and in development work. The most difficult point to determine in building these dumps is the proper location of

DUMP AND CAR IN DISCHARGING POSITION

the pivoting point. If this point is properly located, the dump will discharge the contents of the loaded cars and return to normal position without manual aid.

The proper location of the pivot or dump axle may be found by the aid of the following rule: To one-half the wheelbase in inches add one-half the wheel diameter in inches minus three. This gives the horizontal distance from the rear axle of the car to the dump axle in inches.

The horizontal distance from the center of curvature of the horns to the dump axle would of course be the difference between the wheelbase and the distance found above.

A dump of this type should only be allowed to tip through an angle of about 30 deg., the car being permitted to pass on through an additional angle of about 30 deg., making a total inclination of the car bottom of about 60 deg., the first one-half of which is turned about the dump axle and the second half about the front axle of the car.

After the coal has been discharged from the car its rear wheels return to the dump rails with sufficient force to cause the dump to return to its normal position. A dump of this kind may be constructed easily in the mine shop, and if proper care is exercised in its construction such a dump may be made to work perfectly.

Speeding Up Mining in Shallow Drifts

BY G. H. KIRCHGASSER
Milwaukee, Wis.

An ingenious method of overcoming difficulties in coal haulage has been in operation for some time in the mine of the Logan Coal Co., Beaverdale, Penn. Some drifts in this mine are so low (about 3 ft. headroom) that it is impossible for mules or battery locomotives to enter them. But to mine the coal in these pockets is of course important today in order to meet the demands.

The coal bed in some places in this mine was found to be only about 38 to 44 in. thick. Underlying this was soft shale and earth. To excavate the rooms deep enough to allow mules or locomotives to be used would have meant the employment of many miners, which in the face of a declining labor supply was next to impossible. And even should enough men have been available the cost of the yardage, including the shale and earth, would have made such a method unprofitable.

To avoid extravagance in the use of men and money and still extract the coal from these beds, a scheme was

HOIST HAULS MINE CARS INTO THE ROOM

devised that has proved so successful that since the first operating unit was installed 100 others have been added and the plan adopted throughout the mine.

A pocket is constructed in a drift driven at a slight inclination and off the main heading. The empty car is brought from the main heading and hauled into the pocket by means of a cable wound on a winding drum driven by an electric motor that is automatically started

and stopped by means of an automatic controller. The cable passes around a sheave wheel located at the head of the room and thence to the motor-driven winding drum.

At the entrance to the pocket an electric switch is placed, which when closed energizes the automatic controller which starts and accelerates the motor. The winding drum thus reels up the cable and the car is

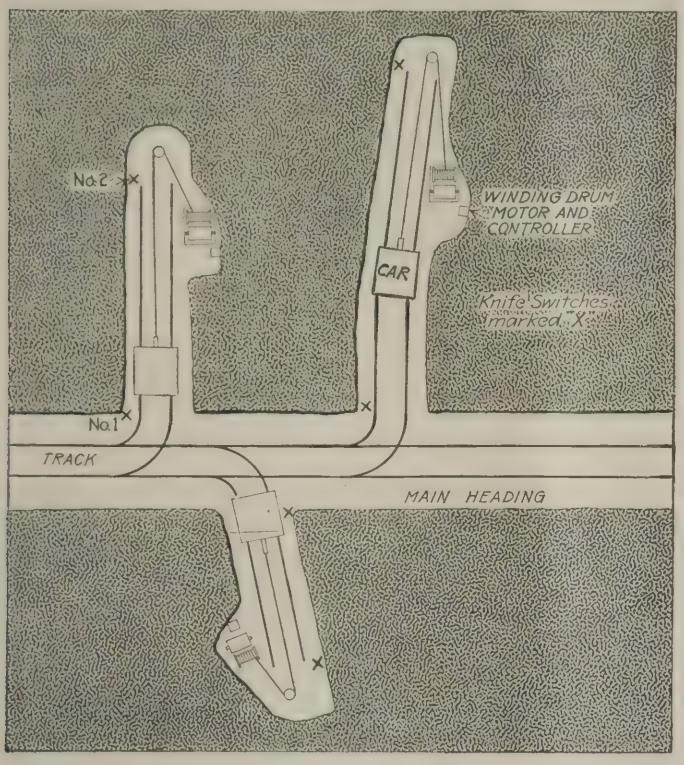


DIAGRAM OF OPERATION OF ROOM HOIST

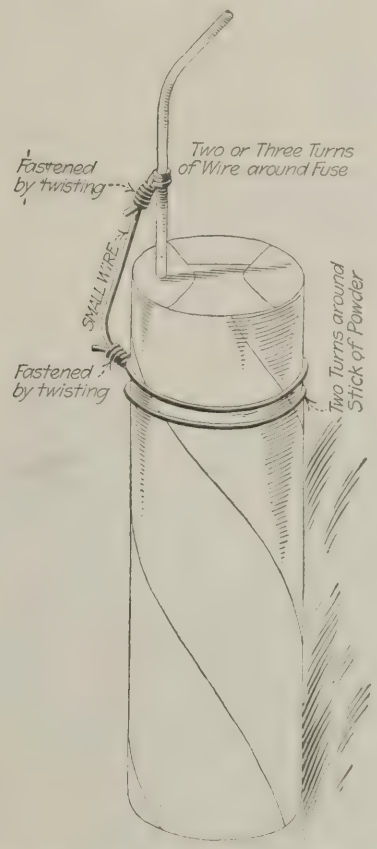
hauled into the room, where it is loaded by the miners. As will be noted from the diagram, there is another switch which is conveniently placed for the operator in the pocket. This the miner opens to shut down the motor, thus giving easy control of the outfit at both ends of the car's travel.

When the car is loaded it is only necessary to release the brake and it quickly coasts down the grade to the main heading, where the cable is disconnected and the car is ready to be hauled out of the mine. Another car is hauled into the pocket by attaching the cable to it and closing switch No. 1 again. One miner can do this—ride on his car into the pocket, throw out the switch, fill the car and coast back to the main heading ready for hooking onto another empty. However, to facilitate the work, there are usually two men to a room. Sufficient cable is provided on each winding drum to take care of rooms of various lengths. Filled cars are assembled in the main headings and hauled away.



The equipment for hauling the cars by cable into the shallow drifts consists of a compound-wound, 3-hp. motor, the cable-winding drum and a C-H type automatic controller which automatically starts the motor when either of the two control switches x are closed, and stops it when they are opened. The controller is mounted on a panel secured to the motor so that the entire unit may be moved easily when work is completed in any location. Ordinarily the controller is placed in a metal case.

The cost of operating this hauling unit is small, since current is only used during the brief period when the car is hauled into the room. The current handled by the control switches x is but a fraction of an ampere, which is a big advantage from a safety standpoint because of the elimination of the danger of accidental burns, flashes or shocks.

Attaching Fuse to Primers

By William Crocker

A method of attaching fuse to primers is shown in the accompanying illustration. I have made thousands of these primers with perfect success. The fuse is anchored to the stick of powder with wire obtained from the strands of an ordinary bell cord which is cut into lengths of about eight inches. After inserting the

HOW THE FUSE IS ATTACHED TO THE PRIMER

copper fuse in the regular manner, the wire is twisted around the cartridge, embedding itself into the wax paper. One end of the wire is twisted around the fuse two or three times. Such a tie will not slip or yield. The whole operation is accomplished quickly—*Engineering and Mining Journal.*

In view of what is known of the chemistry of the various kinds of fuels and the possible advancement of such knowledge in the near future, it is questionable whether the method used in attacking the smoke problem was the best as regards fuel economy. The persistence of smokiness in burning bituminous coals shows that there is room for improvement in methods of burning.—*Bureau of Mines Bulletin No. 135.*

Concrete Foundations, Drift Linings and Reservoirs

By J. F. SPRINGER
New York City

SYNOPSIS — *Concrete foundations for machinery do not as a rule require reinforcement. Here weight and ample bearing area are prime requisites. On yielding soils piling or piers are sometimes required. Concrete drift linings are frequently used. These are usually arched and reinforced. Large tanks and reservoirs are sometimes built. If of large size these require expansion joints.*

THE coal-mine management will at times have uses for concrete where the tensile strength will be of minor consideration. In such cases the reinforcement may be reduced to a small amount or omitted altogether. One caution may be relevant, however. If the foundation, or whatever it may be, is pre-molded, account must be taken of any tensile stresses that may arise in moving it to its final position.

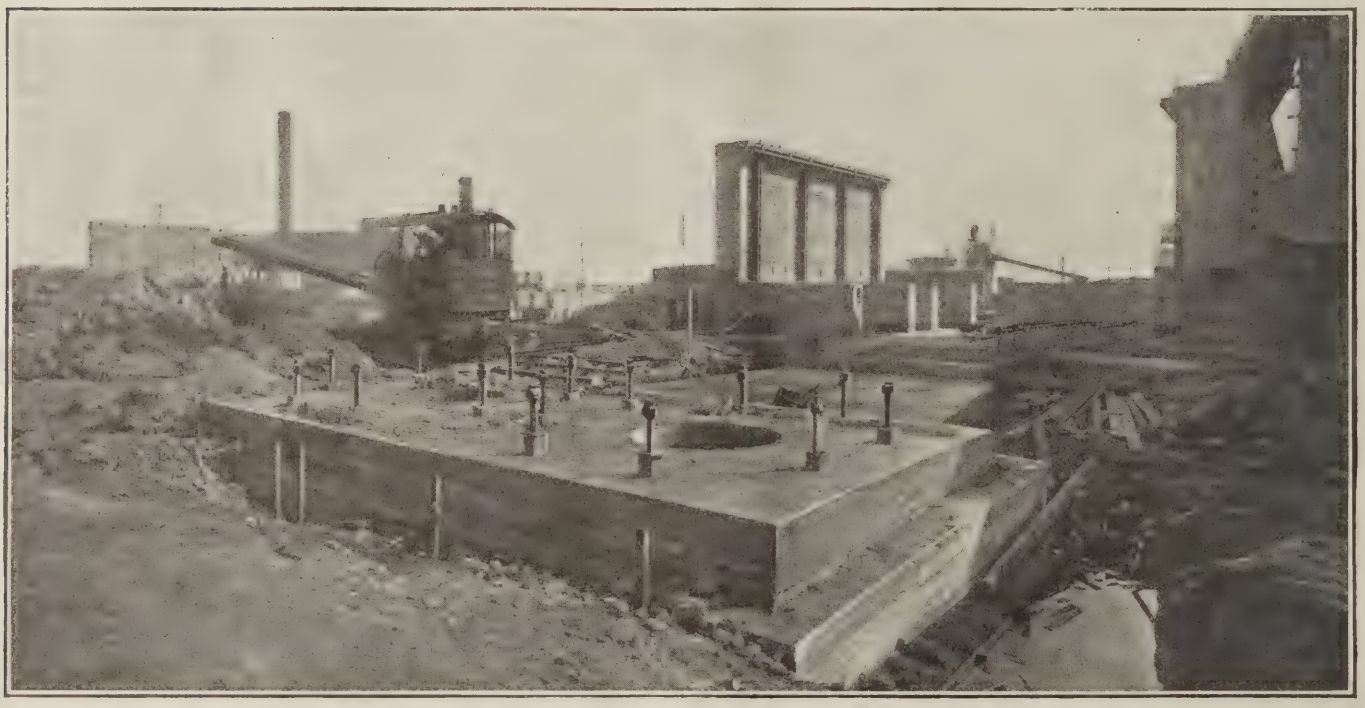


FIG. 1. LARGE CONCRETE FOUNDATION WITH HOLDING-DOWN BOLTS IN PLACE

Foundations for reciprocating steam engines, air compressors, etc., will have to withstand a certain amount of vibratory shock. Ordinarily, the foundation may be constructed satisfactorily without reinforcement. Sometimes further economies are quite permissible. Thus, if the general mass is considerable, "plums" may be used to take the place of some concrete. Such plums (boulder or other rock) should be sound and free from half-detached fragments. The surface should be clean so as to insure a good bond with the enveloping concrete. An efficient way to cleanse plums from clay and other foreign matter is to use a jet of live steam. Another economy consists in providing vacant spaces in the mass at locations where nothing is really required. A considerable cavity may at times be left running like a tunnel from one side of the foundation to the other.

Above ground it will be desirable to have smooth and regular surfaces. Forms will here be needed to give the proper general shape to the mass, so that smoothness and regularity can be obtained. Wood will generally leave an imprint, and the crevices between planks will be represented in the block. If it is desired to avoid these, one of the best means to this end is to use a steel plate lining. The metal should be free from rust and should be greased before the concrete is poured. Crude vaseline, thinned with kerosene, will provide a suitable coating, the object of which is to prevent the concrete from attaching itself. Where wood is used it may be thoroughly wetted down ahead of pouring, the same purpose being in view; or, it may be greased. Below ground the foundation block will frequently require no other form than the sides of the excavation. Irregularity will here be no serious matter.

Concrete foundations and other concrete structures may be built upon a variety of materials. Bearing piles of wood or concrete are suitable. If wood is used and water is present, the heads of the piles should be, say, 1 ft. below the water level to insure that they will not be subjected alternately to water and air. The

FIG. 2. TOPS OF CONCRETE PILES

concrete may then have its base 1 ft. below the pile heads. Concrete piles may be used instead of wood, but the latter has an indefinite life if perpetually submerged in water possessing no substantial chemical action.

If concrete piles seem necessary, there are numerous varieties that are suitable. The pile may be pre-molded and then driven after maturity. Reinforcement will be necessary to cover transportation, handling and driving shocks, and stresses. A conical sheet-steel shell may be forced down and then filled with concrete. This system is probably patented. A similar system, and one that I think is unpatented, is to force down section after section of cylindrical steel shells. At the bell and spigot ends these need reinforcing bands, which are made of moderate thickness and may well be 12 or 14 in. in diameter. They may be driven with the bottom end closed or open. Where driven with closed end, a cast steel tip is provided. Where driven with the end open, it is necessary to clean out the interior after driving. A miniature orange-peel grab bucket may be secured small enough to suit the 14-in. shell. In fact a bucket 10 in. in diameter actually has been used.

However driven, the shell may contain water. This may or may not be removed. In the former case we may close the bottom by a concrete seal as a preparatory measure. If the water is allowed to remain, we may fill in the concrete by using a bottom-dump bucket; or we may employ a tremie, which is a simple device for placing concrete under water.

The steel shells, whether conical or cylindrical, are left in place. To withdraw the shell and leave soft concrete in the soil would be a somewhat doubtful procedure. The pile might or might not be pinched in two by constrictive action of the soil.

A caution might well be given at this point relative to the difference between a pile and a pier. A pile is supported, in part at least, by skin friction; a pier derives its support from the material beneath its foot or base. If a pile is put down through material supplying no skin friction—as thin mud, quicksand, water—then we may have really a pier. This will be satisfactory if the pile will resist buckling and all wrong if it does not. Naturally, if a pile is really to perform the service of a pier it should be suitably reinforced.

In most cases piling under foundations will be unnecessary. The block is based immediately on the soil or rock. Clay is, however, not to be accepted as a satisfactory footing without knowing something more than that it is just clay. The possibility of its being partially carried away by water is to be considered.

Sand is a good support for concrete, particularly if it is clean and compact. Quicksand must be vigorously avoided. Ordinary alluvial soil will often be satisfactory. Lof and Rushmore consider 1000 lb. to a square foot a proper allowance for such soil for machinery foundations. But they also say, "For soft or alluvial soils piling is almost always required." This is, however, a question of weight of machine and block, and of area of foundation base.

The permissible pressures on concrete vary, partly because the factor of safety to be allowed is a matter of controversy. It is understood that in Boston the building laws permit only a maximum of 55 lb. per square inch; while in New York they sanction pressures up to 200 lb. per square inch.

These permissible loads probably contemplate no considerable vibrations. Where a rock crusher or similar machine is to be installed, account must be taken of the continuous shock and jar, and adequate allowance made. In all cases, whatever the underlying material, the block may be flared out so as to secure a greater total support.

Where the block rests on the surface or has only a shallow excavation, it may be necessary to tie it to the rock or other support. To do this, tie-rods or dowels are embedded in the base of the block and in the underlying material. There are, according to A. Del Mar, three most popular forms for these rods. (See Fig. 4). All have a knob at the upper end. They differ in the form given to the lower extremity. In one case the lower end is furnished with upward-

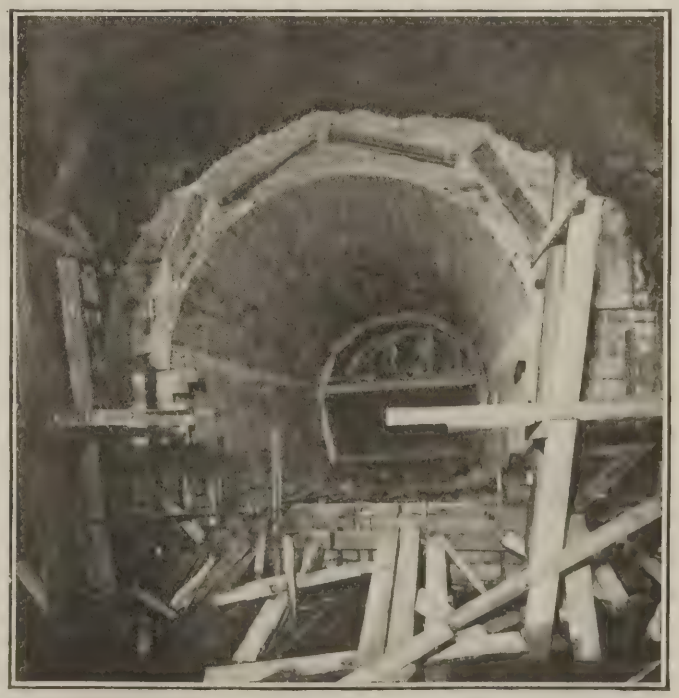

FIG. 3. END VIEW OF CONCRETE TUNNEL LINING

pointing barbs made by driving a chisel obliquely into the side of the rod. The barbs may be arranged on all sides and to cover a foot or two of the lower end of the bar. The gross diameter of the barbed portion should be larger than the hole in the bedrock; the shank should be distinctly smaller. When this bar is driven into the rock the barbs give a little, but they resist an effort to pull the bar out. One of the other popular forms is made by splitting the bottom end for a few inches and inserting a suitable wedge. The third form is made simply by upsetting the metal at the bottom end until a considerable bulge is formed.

In all cases, after the hold-down rods have been driven into place in the rock, the holes are to be filled with cement grout or mortar. In the latter case a proper formula for proportioning cement and sand is 1:1. A good foundation is said to have been secured in a stiff blue clay by means of such tie-rods. They were arranged to radiate from the foundation block and thus secured an extended area of grip on the clay.

It will ordinarily be necessary to use a rich mixture of concrete for machinery foundations. Lof and Rushmore in their recent work on "Hydro-Electric

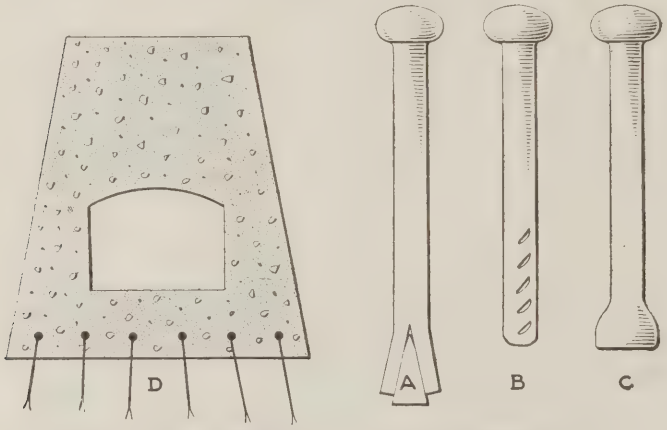

FIG. 4. VARIETIES AND ARRANGEMENTS OF FOUNDATION DOWELS

Power Stations," say: "A mixture of one part cement, three parts sand and six parts gravel or broken stone forms a concrete that is extensively used, and which has given perfect satisfaction for machine foundations." We may, of course, use this same mixture for any other similar use.

The concrete should not be brought to quite the level of the underside of the bedplate of the engine, compressor or other machine. About 1 in. is a proper vertical interval to allow. Assuming that the machine anchor bolts have already been set in position and that the machine has been placed with all the bolts in their holes or slots in the bedplate, the next step is to block it up 1 in. Steel or iron blocks and wedges or shims may be used for this purpose. These blocks may naturally be placed before the machine is let down at all, provided they are not liable to displacement. The machine is now leveled and oriented with the degree of precision that may be necessary for the particular case. These adjustments should be made as perfect as ever will be desired, as it will not be an easy matter to correct them later on when the machine has been grouted to the block and the grout has hardened.

There seems to be a difference of opinion as to whether it is better to use a thin, easy-flowing grout poured in to the proper level or a rather stiff grout well packed beneath the bedplate. The latter procedure is preferred by a large engine company. The packing is done by hand, with the aid of a metal rod or bar with a suitable flat surface to force the grout into place. A suitable tamping rod may be made by cutting off a short length, say 16 to 20 in. long, from a flat bar ¼ in. thick and 1¼ in. wide. A block may be held as a kind of backstop for the half-dry mortar when we use the tamping rod. In this way we are able to pack the mortar tightly. The rod may well be used, now on the outside of the bedplate flange and now on the inside, the idea being to get a hard, compact layer of mortar underneath the flange for its full width. It is claimed by some that a soft, easy-flowing mortar cannot be made to set properly against the under surface of the frame. In consequence "the machine is pulled out of line when the foundation bolts are tightened up. Many engine troubles are occasioned by this way of setting."

A good mortar for grouting in machines follows the formula 1:1½. The sand and cement are first to be mixed dry. A small amount of the dry mixture may then be dampened enough to make it "about as damp as molding sand, or just so it will hold together when pressed into a ball by the hand." After this dampened mortar has been used up, another batch is wetted and used immediately. The concrete surface of the foundation should be thoroughly cleaned and wetted before applying the grout. A warning is to be given here. A quick-setting cement may develop heat. This may or may not be sufficient to affect (expansively) the iron in the bedplate to an appreciable amount.

Reference has been made to the anchor bolts which hold the machine to the foundation block. In some cases it is desired to have these removable. Vertical holes are arranged and the bolts provided at their bottom with a removable head or nut which bears directly or indirectly against a shoulder in the concrete at the bottom of the holes. Essentially, these bolts are long rods threaded at both ends and provided with nuts, etc., by means of which the machine and foundation are bound together. The cavity in the concrete block where the bottom accessories of the rod are located may be accessible or inaccessible from one side of the block. Where the anchor rods are not removable, it is customary to embed the lower ends in the mass of the concrete. There may be a washer plate and nuts, as in the case where a removable anchor bolt is installed, only in the present instance these are embedded in the concrete mass and became part of it. Of course, the plate and nuts are there simply to add to the resistance to an upward pull on the rod.

Whether anchor bolts are removable or not, it is customary to provide either cylindrical or tapered holes extending down from the top of the concrete a considerable distance, thus securing a free space around this portion of the rod. The object in view is to make it possible to swing the upper end a moderate amount in any direction. There would, perhaps, be no need for bending the rods if the plan of the bedplate could be relied upon with respect to the positions of the holes or slots. It seems that in actual practice no substantial reliance can be put in any blueprint showing foundation bolt positions.

An annular space at the bolt top permitting a movement of 1 in. in any direction is good practice when constructing the foundation block. This space may be diminished to little or nothing at the bottom if a tapered hole is provided. As to the question of making a choice between a plain cylindrical hole and a tapered one, it may be said that the latter provides a better shoulder for the plate at the lower end of the rod when it is desired to have the whole thing removable. Where the lower half of the rod is actually embedded in the concrete mass and goes down into it well below the bottom of the hole, it will generally be altogether unnecessary to taper the hole.

Naturally, it is easy to provide a form for the cylindrical hole by simply using a piece of pipe. Whatever shape of form is used, it may be either left in or removed after the pouring of the concrete. If the form is not to be left in and a tapered hole is desired, a pyramidal wooden form may be employed.

The anchor bolts must be placed quite accurately before the concrete in which they are embedded is poured, and the casings must be located rather precisely with reference to the bolts. It is customary to use wooden templets as a means of suspending rods and casings and fixing their positions. After the wooden framework is ready, the exact locations of the bedplate holes or slots, as shown by the machine builder's blueprint, should be marked on it. At the proper locations holes are bored for the anchor rods. We have now a means of hanging them inside the form used for the foundation block.

The suspension of the casings will hardly be as easy a job. They must hang at a precise level, if they are to be left in, and they must be held central with the anchor bolts. The following method is perhaps one of the best for accomplishing this result. As a 1-in. space is to be left between the top surface of the concrete and the under surface of the bedplate, we may arrange blocks on the under side of the templet to reach down to, say, within ¼ in. of the level at which the pouring of the concrete is to stop. The blocks are located at the holes for the rods and are suitably bored to receive them. They are also counterbored on the under side to the depth of ¾ in. to provide seats for the upper ends of the casings.

At the bottom ends of the casings a steel washer of suitable size, when placed upon the rod to hold the casing central therewith, may be used. If the rod is to be irremovable, this washer may be left in. A washer of different metal from the rod should not be employed, as in that case electrolytic action may possibly be inaugurated later on.

In order to prevent concrete from entering the casing at the bottom and blocking up the hole more or less, this may be filled with loose material of such a nature as to be easy to remove later on. Paper, excelsior, etc., may be employed. In fact, this packing may sometimes be used to hold the casing central.

Where the rods are to remain in place the holes may, if desired, be filled with cement grout. This is not done until the machine is set in precisely the position wanted. It should be done, ordinarily, before the 1-in. space between foundation and bedplate is grouted up or simultaneously with this action. Whether to grout up the holes or not will probably be answered differently by different persons. Once this is done no slight variations in the bedplate positions can well be made. On the other hand, when grouted up, we are relieved of the necessity of paying attention to corrosive action or the like in so far as the bolt is concerned below the top of the block. Furthermore, we have undoubtedly a more rigid hold on the machine. On the whole, it appears to me that for a mine these two considerations ought to outweigh the first and give the decision to the hole grouted up to the top. The precise setting of the machine should be done at the beginning and should not need a second attempt.

What ought to be the length of the bolt in the hole and what the length of the bolt embedded in concrete? As to the former, good practice seems to warrant making it 25 or 30 times the diameter of the rod. It is simply a question of what ought to be the length of a rod which is to be deflected 1 in. by bending. As to the latter question, no such short answer can be given. Deep embedment will be advisable where strong resistance is to be provided. Generally speaking, the

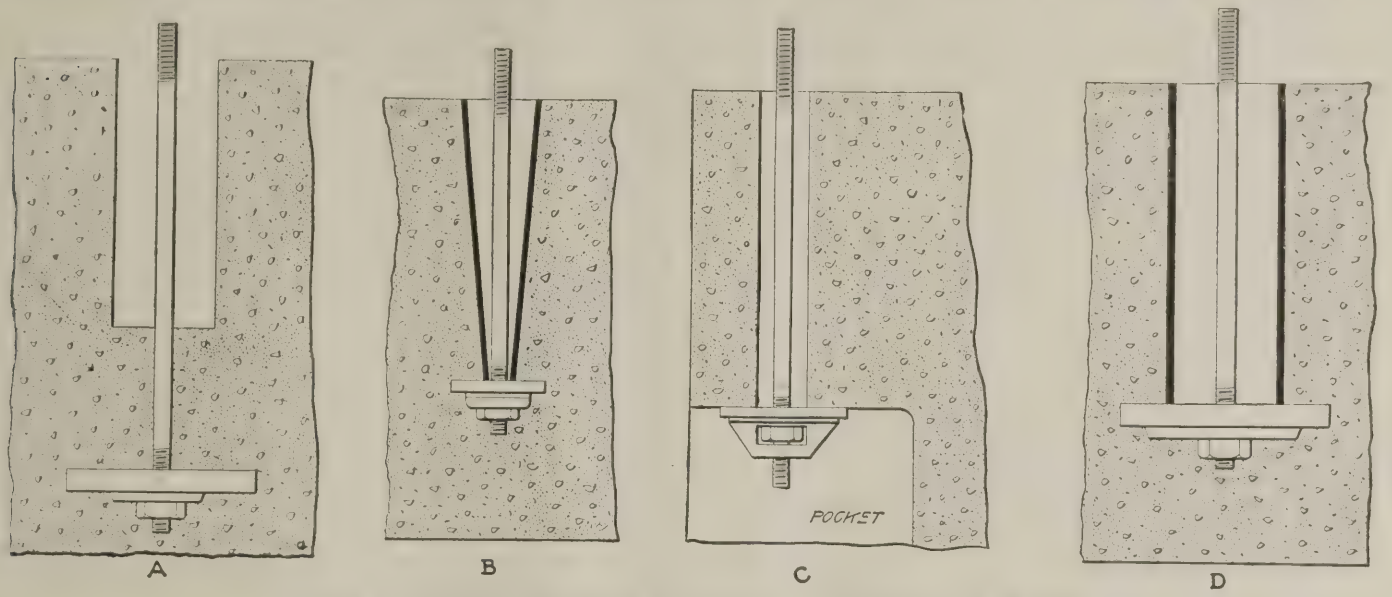

FIG. 5. VARIOUS METHODS OF PLACING HOLDING-DOWN BOLTS

depth of embedment will be at least equal to the length of bolt in the hole, and usually more.

Where bolts are to be removable, we have (1) the inaccessible cavity where the anchor-bolt plate and nut are housed or (2) the accessible cavity. The bolt will, in both cases, be naturally separated from the nut by turning from above. The thing to provide for is to get the same or a duplicate bolt in threaded engagement with the nut later on. This ought to be a fairly simple matter to prearrange when a tunnel from the side is provided. For the inaccessible cavity, however, a good solution seems to be an anchor-bolt plate provided with an open chamber for the nut. This chamber and the nut may be so dimensioned that there is little or no play when the plate is once set in place. The nut need not be subject to a horizontal displacement of more than about ⅛ in. when the anchor bolt is disengaged and withdrawn. The bolt can be returned and will find the hole in the nut if it is simply provided with a conical tip.

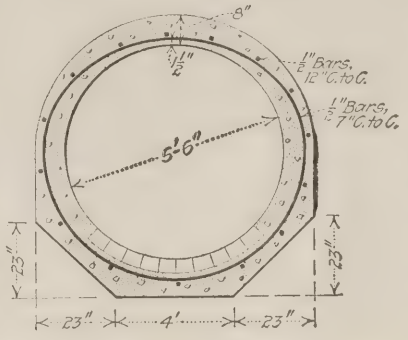

FIG. 6. CIRCULAR SEWER LINING

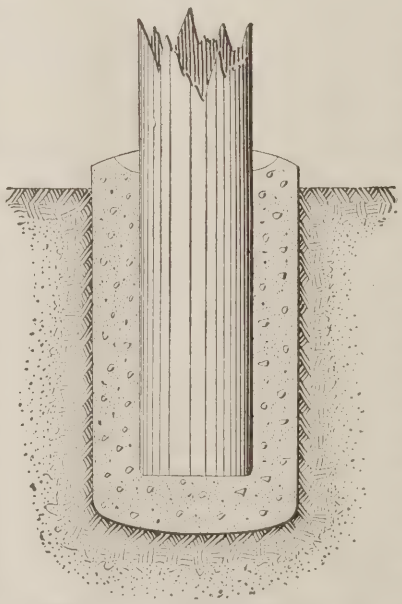
Concrete is exceedingly suitable for the purpose of providing anchorage for guy ropes, tie-back rods and the like. The resistance to the guy is ordinarily supplied by the weight of the block and of whatever may be loaded onto it. A simple method of getting the added resistance of a load is to bury the block under earth or rocks. Concrete made with crushed rock has a specific gravity of about 2¼, so that it will be easy to calculate the weight of an anchor block, remembering that water weighs 62½ lb. per cubic foot.

In constructing such a block it should be remembered that plain concrete is weak in tension. Consequently, we can hardly expect to develop the full resistance of a block if we simply anchor the guy in it after the manner used in securing an anchor bolt for a machine. There should be a branching out of steel connected with the anchor rods so as to involve the bulk of the block and not depend upon any tensile strength of the concrete.



A concrete lining for tunnels and passages is often employed where permanent construction is in view. Thus a main haulage road might well be a proper location for the use of concrete. A roof only may be what is wanted. This may be put in in the form of a semicircular arch, the concrete starting on one side at or below the level at which curvature begins and ending at or below the same level on the other side. The excavation for the arch will naturally be made deep enough to take care of a sufficient bulk. The reinforcement may be both longitudinal and transverse. In many cases it will be possible to make up lengths of the combination of both kinds of reinforcement and set them in place as excavation and concreting progress. It may seem best to carry the concreting down to the floor and thus provide side walls as well as an arched roof.

A center form of some description will be needed. This may consist of a framework of wood on which wooden lagging has been nailed. Such centers may be made in short lengths and used again and again. The material on which the ends of the arch test should be quite substantial, as the effect of using an arch is to concentrate and transfer the overhead load to this material. Where the arch is to terminate on the sides at about the level of the commencement and end of curvature, it has been recommended that the sides provided by nature be given a thin facing of concrete as a protection against weathering.

The position of the circular reinforcement has much to do with the strength of the arch. The top region of the arch is much like a cross-beam. The upper part is under compression while the lower part must bear tensional stresses. Consequently, the circular reinforcement should be located low at the top of the arch. On the sides it may be placed further from the center of curvature. At the level of the center of curvature the reinforcement may be set near the excavation surface. In consequence of the foregoing dispositions, the circular reinforcement will not be truly circular, but rather elliptical.

In the construction of circular concrete sewers and similar conduits it is approved practice to set the curved reinforcement elliptically. (See Fig. 6.) Above and below the center the reinforcement is close to the inner surface of the tube; on the sides it is near the outside surface. Where it seems advisable a steel form may be used. One or two patented systems of collapsible steel forms for just such work as arches are also available. In any case some method of preventing the adhesion of the concrete to the form will be necessary.

The placing of the concrete will at times require close attention. There is no great trouble in filling in the sides. If the form is too long to permit this to be done from the end, the arch lagging may be left off until the sides have been placed. In fact we may have set at one time only just the proper height of lagging to retain the amount of concrete then to be placed. It may be necessary, however, to secure the lagging to the ribs from the inside. The most difficult part of the work will doubtless be that of placing the concrete in, say, the top 60 deg. of the arch. If the mine has a compressed-air equipment, it may be advisable to get a pneumatic transmitter for placing tunnel concrete, especially that which goes into the crown of the arch. When a practicable type is employed the concrete may be piped from the transmitter to the point of use. Transmission may be effected around curves and up to levels

FIG. 7. A CONCRETE POST FOOTING

100 ft. above the transmitter. The pneumatic transmitting machines are not to be confused with sprayers.

As to the kind of reinforcement, steel bars are usually employed; but other material is, it appears, being used abroad. I wish neither to recommend nor discourage the use of strands of old wire rope. Prof. George Knox seems to be, if not an advocate of wire rope reinforcement, a countenancer of it, for he says: "The cheapest reinforcement for this kind of work is the strands of old steel haulage and winding ropes. Under normal conditions it may be only necessary to put the strands in longitudinally, but where extra support is required it is advantageous to have them crossed with transverse strands; and with very bad roof weights two sets of longitudinal and transverse strands may be put in together, with a few extra longitudinal wires between the sets. An important point to note in connection with the reinforcement is that the ends of the strands should terminate irregularly, so as to overlap the next set at different points and prevent anything in the nature of a 'joint' being formed."

The following formula is in effect the one recently recommended by Professor Knox for use where great strength is required: 1 : 1⅝ : 5⅝. The coarse aggregate consists of granite in two sizes, 1½ in. and ½ in. I rewrite this formula, dividing the coarse aggregate in accordance with the amounts used and represented by two numbers connected by a plus sign. The first of the two numbers represents the smaller aggregate. The rewritten formula is: 1 : 1⅝ : 2⅝ + 3.

If the underground roadway is dry, the following formula is given as permissible: 1 + 8 : 0 : 24. This is to be interpreted as follows: There is, first of all, 1 part of cement; to this are added 8 parts of freshly burned lime; no sand as such is employed; there are 24 parts of hard shale (from ripping), varying in size up to 1½ in. There will doubtless be in the shale a percentage of an equivalent of sand.

The wooden pole is used in many places in or around coal mines. I am not now speaking of props. Such poles, whether employed as supports for lighting fixtures, electric wires or for some other permanent use, are apt to rot at the base. Moisture and fungi are said to be "the two prolific causes of decay and shortened pole life." The plain cementing of the base of the pole seems to have been tested out and found inadequate. The failure to prevent bad effects seems to be attributed to the insufficiency of the joint between the pole and the inner surface of the cement coating.

It is conjectured that water gets into the joint and remains there. It is understood that some poles with cemented bases set in soils which permit the escape of water really rot faster than others set in what appear to be bad soils. The trapping of water inside the cement shell would appear to explain this. Water is not necessarily an enemy of wood. If a piece of wood is perpetually submerged in water having no chemical action, its life will probably be excessively long It is the change from wet to dry and back agair that seems to work the damage.

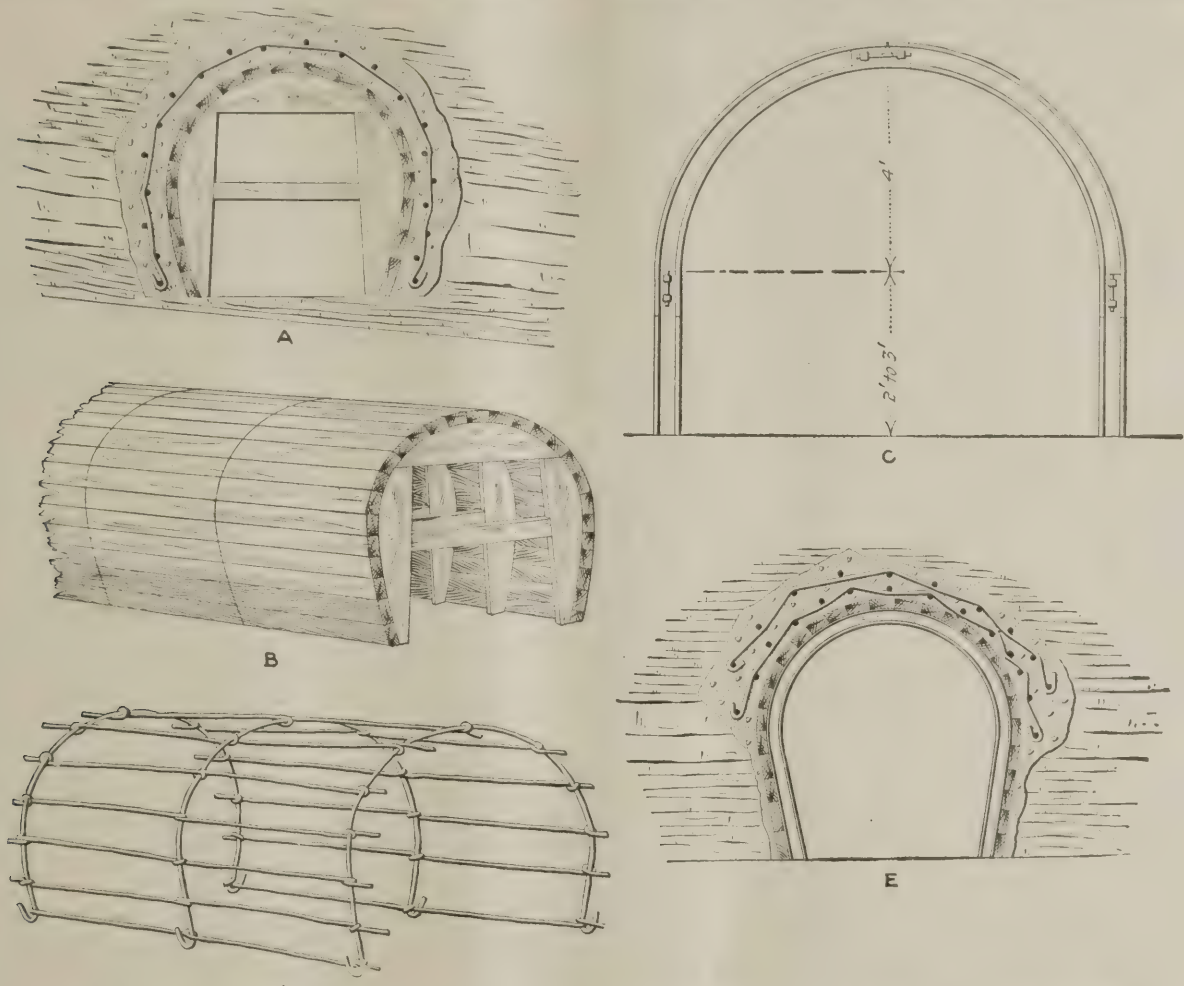


FIG. 8. ARRANGEMENT OF REINFORCEMENT AND ARCH CENTERS FOR TUNNEL LININGS

It has been proposed to use a tar seal to prevent the entrance of moisture into the space between the concrete cup in which the pole stands and the pole itself. That is to say, the concrete is poured in the usual way to make an envelope all around the base of the pole and beneath it. The top of the cup may be brought up a little above the general surface and rounded. When this concrete is still soft, a gutter may be cut out all around the top next the pole. Hot tar is poured into this annular depression and forms a seal against moisture. (See Fig. 7.) This may be expected to be effective until the pole cracks. The crevices in the wood now form new avenues for the entrance of water. These may be stopped up with tar and the seal again made effective.

Concrete-lined pits are often used as containers or reservoirs. Such pits have been constructed of large size for the purposes of retaining house water and also coal in wet storage. A sloping side is a convenient design. The floor may be level; or, if drainage is desired, approximately so. Compact sand having no tendency to flow forms a good foundation. Clay should be investigated before being rated as all right. The amount of concrete can often be reduced markedly by using steel reinforcement. Steel bars supplemented with wire mesh are usually most suitable. If it is desired to make the shell impervious this may be approximately done by providing a rich, dense layer of concrete for the inner lining, while the remainder of the shell may be constructed of a more economical concrete. However, if the pit stands in water and the head has any substantial value, the complete emptying of the pit may be accompanied by the breaking away of this inside lining. This is a chance that may sometimes have to be taken.

The steam spraying system is adapted to putting on a dense layer. As to the pneumatic sprayer, I do not know. The layer may consist of a rich, cement mortar, 1:2 or 1:1½; or a pebble concrete, the coarse aggregate being rounded pebbles of small size. Some such formula as 1:2:2 may be followed. There are various waterproofing compounds which may be incorporated with the concrete, but I cannot give a thoroughly reliable word as to their efficiency. If it is desired to make the pit absolutely impervious to water from the outside, a brick and mastic combination may be used for the outer shell.

If the floor area, considered in connection with the extensions up the oblique walls, has a length or a breadth in excess of, say, 40 ft., it will be advisable, generally, to use expansion joints. These may run both lengthwise and transversely.

Vancouver Island Production in June

The Vancouver Island collieries produced 137,895 gross tons of coal for the month of June, a little over 5000 tons less than the quantity produced in the month of May. The tonnage produced by the various companies was as follows:

	Tons
Canadian Western Fuel Co., Nanaimo colliery	61,685
Canadian Collieries (D) Ltd., Comox colliery	47,926
Canadian Collieries (D) Ltd., Extension colliery	18,367
Pacific Coast Coal Mines, Ltd., South Wellington	8,417
Nanoose Collieries, Ltd., Nanoose colliery	1,500
Total	137,895

For the first six months of the year the Vancouver Island collieries produced 857,131 tons, a decrease of 24,881 tons as compared with the same period last year. The producing mines are three less than was the case in 1917—namely, the Jingle Pot mine, South Wellington mine, Pacific Coast Coal Mines, Ltd.: and No. 4 mine, Canadian Collieries (D), Ltd., Extension colliery. The Jingle Pot mine alone produced 48,885 tons during the first six months of last year, so that in spite of the loss in tonnage from this mine and the others since closed down the tonnage has been well maintained.

The tonnage produced by the various companies for the first six months follows:

	Tons
Canadian Western Fuel Co., Nanaimo colliery	389,984
Canadian Collieries (D) Ltd., Comox colliery	280,151
Canadian Collieries (D) Ltd., Extension colliery	118,148
Pacific Coast Coal Mines, Ltd., South Wellington	51,181
Nanoose Collieries, Ltd., Nanoose colliery	17,667
Total	857,131

The Canadian Western Fuel Co., at its Nanaimo colliery, has made a gain of 63,515 tons for the first six months of the year. The Canadian Collieries (D), Ltd., at its Comox colliery, has made a gain of 21,233 tons thus far, but has lost 32,014 tons at its Extension colliery. This is accounted for by the closing down of No. 4 Mine as previously mentioned. The Pacific Coast Coal Mines has a loss in output of 36,816 tons for the first half of the year. This is explained by the abandonment of the South Wellington mine.

The Nanoose collieries has made a gain of 9086 tons, while the Jingle Pot mine of the Vancouver Nanaimo Coal Co., as stated, has produced no coal this year while for the first half of 1917 its output was 48,885 tons. The No. 5 mine of the Canadian collieries is not producing about 100 tons daily from development work.

The new mine at Cassidy's Siding, Esquimalt & Nanaimo Ry., which is being opened by the Granby Consolidated Mining and Smelting Co., is now producing coal from the development work. Some 1000 tons has been dumped at the surface of the mine but no shipments have been made as yet. The Island tonnage should be somewhat augmented by the production of this colliery before the end of the year.

A pair of shafts are now being sunk for the purpose of opening up a new mine on the company's farm near Nanaimo by the Canadian Western Fuel Co., and coal will probably be reached by October of this year and shipments made before the end of the year.

The coal produced by the mines of the Nicola-Princeton District for the first six months of the present year was 19,972 tons in excess of that produced in the same time in 1917. The tonnage to the credit of the several companies the first six months of 1918 follows:

	Tons
Middlesboro collieries	54,698
The Fleming Coal Co.	12,637
Princeton Collieries, Ltd.	22,148
Total	89,483

The Middlesboro collieries has made a gain of 19,152 tons over last year and the Fleming Coal Co. (formerly the Inland Coal and Coke Co.) has exceeded last year's showing for the same period by 5198 tons. The Princeton collieries has made a gain of 355 tons. The Merritt collieries has not been operating this year, while last year for the first six months its output was 4782 tons. Despite this handicap the district shows an increase of 19,152 tons.

Lubrication of Air Compressors

By W. H. CALLAN
Chicago, Ill.

SYNOPSIS — *Oil salesmen seem to believe that a heavy oil is necessary to the efficient lubrication of air-compressor cylinders. Practical experience would indicate, however, that a fairly light oil might be used with entire success.*

THE lubrication of the air compressor, steam cylinder, main bearings, crankpin, crosshead pin, crosshead guide, etc., does not differ from that of the ordinary steam engine. The means and methods employed are well known and understood; hence the discussion in this article will be confined to that of air cylinder lubrication only.

A number of years ago, when the compressor business was young, considerable trouble was experienced in procuring a suitable oil for lubricating the air cylinders of compressors. After considering the matter for some time, it was decided by the company by which I was employed that an expert on the subject should be consulted. Accordingly, the matter was taken up with a well-known oil company, whose representative called upon us and, after making a careful examination of the conditions, reported that the trouble was entirely due to using an oil of too light body and too low viscosity to withstand the high heat of the compression. He stated that the oil used was gasified, due to the high temperature of the air, and that it passed off in vapor, leaving the cylinder wall without lubrication. The expert thereupon recommended an oil which he considered suitable for our use. The particular grade happened to be of 26 Beaumé gravity with a flash point of 515 deg. F., a fire test of 555 deg. F., and a viscosity of 130 S at 212 deg. F.

No Increased Efficiency Was Secured

After using this oil for some time, we found no improvement in the operation of the machine; in fact, it appeared to be laboring and the temperature of the discharge air was high. After several days of operation with this new oil, the cylinder heads were removed, the valves taken out and a careful examination made. The cylinder wall seemed to have a sticky, plastic coating; the air passages and discharge cavity of the cylinder showed signs of dark deposits, while the faces of the valve seats were covered with a black, hard coating. This hard formation on one side of the valve seat caused the valves to leak, hence the increased temperature of the discharge air. The sticky coating on the wall of the cylinder was responsible for the increased friction.

The respresentative's attention was called to this condition, whereupon he suggested that a little lighter oil be used. This time he recommended one with 27½ Beaumé gravity, a flash point 450 deg. F., a burning point of 500 deg. F., and a viscosity of about 125 S at 212 deg. F. We asked him if he did not think this was a little too heavy a grade for air-cylinder lubrication. He assured us it was not, and stated that, in order to withstand the high temperature of the compressed air, it was necessary to have a rather low gravity and high viscosity oil, with a flash point above the temperature of the air.

After we had used this grade of oil for some weeks, a further examination was made; and while the cylinder wall appeared considerably better, the valve passages and discharge cavities of the cylinder were badly coated with a hard deposit. When this matter was again brought to the attention of the expert, he suggested that we reduce the amount fed into the cylinder. This was done with great care until we were only using three drops a minute in a 14 x 14-in. cylinder running at 150 r.p.m. But even under these conditions the deposits in the valve passages and the discharge cavities of the cylinder continued to form as long as this oil was employed.

The expert happened to come our way several months afterward, and I called his attention to the condition experienced with his oil. In regard to the amount we were feeding into this cylinder, he said this was reduced to a point that he thought was the minimum. His reason given for the formation in the passages was that the residuum of all oils is carbon, and that it therefore was no doubt due to carbon deposits. At the same time he assured us that the oil he had recommended was the best procurable for the purpose, and that we should go ahead and use it without any fear.

Deposit Built Up Rapidly

This was done, but the formation in the discharge passages seemed to be building up rapidly despite the fact that only a small quantity of oil was being fed into the cylinder. These formations finally collected to such an extent that it was necessary to clean the passages in order to avoid the hazard of an explosion. The passages were accordingly cleaned, and some of the material removed was analyzed and found to contain about 1.5 per cent. free oil, 11 per cent. rust, 5 per cent. decomposed oil, 30 per cent. mineral ash, 10 per cent. coal dust, while the remainder was foreign matter, or residuum. A further investigation revealed the fact that our intake was exposed to such material as coal dust, mineral ash, shavings, water, etc., as well as some air.

After cleaning the compressor, and safeguarding the intake against dirt and dust, we procured another grade of oil which in our own judgment was more suitable for the work, since in the meantime we had made investigations and studied the question to some extent. This time we procured an oil of 31 Beaumé gravity, a flash point 375 deg. F., a burning point 420 deg. F., and a viscosity of 200 S at 100 deg. F. We started by feeding three drops per minute. Finding the cylinder copiously oiled, we reduced the feed to two drops a minute. The compressor was operated in this condition for a considerable length of time with practically no trouble from carbon deposits.

Experiencing such good results from this light oil, and by this time disbelieving in many of the virtues claimed for low gravity, high flash point and heavy viscosity, we were prompted to try another grade of oil, selecting this time one having a gravity of 33 Beaumé, a flash point of 380 deg. F., a fire test of 420 deg. F., with a viscosity of 140 S at 100 deg. F. We used the same quantity as before—namely, two drops per minute in a 14 x 14-in. cylinder running 150 r.p.m. This oil was used for years without any trouble from lubrication, valve leakage or carbon deposits.

The oil representative made his regular calls on us, and each time we told him what we were doing; but he assured us we were on the wrong track and that sooner or later would get into trouble. After continued tests, however, and careful observation of all conditions, we became satisfied that the latter oil is the most suitable for air-cylinder lubrication when working against a 100-lb. pressure, with either single- or two-stage compression.

An Old Friend Calls

One day an old friend of mine called, who also happened to be an expert representing one of the leading oil companies. I related to him my experience with air-cylinder lubrication and, somewhat to my surprise, he too assured me that we were using the wrong oil and said, "You know you get not less than 400 deg. C. F. in your air cylinder when working against 100 lb., single stage." With this I agreed. I then asked him how he knew we were wrong, and what means he employed for ascertaining the proper grade of oil for air-cylinder lubrication. He then proceeded to explain the method his company's engineers use in determining the proper oil for different kinds of service.

He explained this in part:

You have agreed that the temperature of the air is 400 deg. Our test would be conducted as follows: Take a block of cast iron 6 or 8 in. square and 2 in. thick, place this block on a layer of sand in a shallow iron pan and pack the sand closely around the cast-iron block, then put a gas burner under the pan and turn on the heat slowly. The top surface of this block is polished and is provided with a drilled hole into which a thermometer is inserted. Heavy steam-cylinder oil is poured into the hole around the thermometer bulb so as to make a close heat contact. When the thermometer rises to 400 deg., lower your gas burner until the thermometer remains steady at this temperature. Then take your different samples, dip the point of a lead pencil into the oil, hold the pencil 2 in. from the surface of this iron block and allow a drop to fall on the hot polished surface.

When such a test is made with the grade of oil from which you say you are getting successful results, we find the drop spreads out to about 1⅛ in. in diameter, smokes a little, dries up, and is evaporated in ten seconds time, leaving the surface perfectly dry. With a higher grade of oil having a flash point of 450 deg. F. and heavy viscosity, when the drop falls on the surface of this polished block it spreads out to about 1¼ in. in diameter, smokes a little, but after five minutes the surface is still oily. Thus we have proof that this is the proper oil to withstand such service as you get in your air-compressor cylinder.

Then I asked him what he thought the temperature of the surface of the cylinder wall was when the air in the cylinder was at 400 deg. F. He hesitated a little, then said he believed it would be about 25 deg. F. less than the temperature of the air. I disagreed with him here, saying this did not seen right, as the water-jacketed wall should be much cooler than the air. After some discussion we went into the office and consulted some authorities on the subject; we found some tests had been made abroad on the temperature of the cylinder walls in an internal combustion engine, where, with an explosion temperature of 2700 deg. F. and an average temperature through the cycle of 950 deg. F., and the water in the jacket at 200 deg. F., the inside surface of the cylinder wall did not go above 267 deg. F.

When my friend was shown these figures he was nearly speechless, and admitted that he had never thought that the temperature of the wall of an internal combustion engine cylinder, with an explosion temperature so high, could remain as cool as this authority stated. However, since the character of the authority was such that it could not be questioned, it was accepted by the oil expert. I then asked what he thought the temperature of the air cylinder wall should be when the air does not exceed 400 deg. F., in answer to which he said he did not know, but did not believe it would be much above the temperature of the water in the jacket.

As a matter of fact, the temperature of the inside of a water-jacketed cylinder wall is not more than 30 deg. F. higher than the temperature of the jacket water, as long as the water does not boil; and, since this is the true condition, what is the use in employing oils of low gravity, high fire test and high viscosity to meet a condition such as this? The temperature of the inside surface of the cylinder wall on an air compressor is little, if any, above the temperature of the surface in the main bearing of the ordinary Corliss engine.

High Viscosity Is Not Essential

From this it appears that the ordinary oil expert who lays much stress on high viscosity and high flash point has not considered the true conditions. Furthermore, it has been shown in this article that the cause of carbon deposits in the passages of an air cylinder is not always entirely chargeable to the residuum of oil, but in many instances is due to using a lubricant of too heavy a body, which adheres to the passages of the cylinder. Also, when the inlet is not properly protected from foreign matter, all such material as coal dust, fine ashes, shavings, waste, etc., is drawn into the cylinder and deposited on the sticky surfaces coated with this heavy oil. This foreign matter, with additional oil, gradually builds up until the passages become choked. The air valves now begin to leak for some reason, thus increasing the temperature, until finally this sometimes reaches a point as high as 500 deg. F. when compressing to 100 lb. single stage. If there are many shavings or much coal dust deposited in the passages, this is apt to char and become incandescent. When this takes place the temperature of the air rises rapidly, and as a consequence the pressure increases quickly to a point beyond the strength of the receiver, and results in what is generally called an explosion.

It is my opinion that no violent explosion ever takes place in the ordinary air compressor, unless kerosene, gasoline or some such material is introduced into the compression space.

In my personal experience some years ago with a two-stage compressor where the intake had been neglected and also the wrong grade and quantity of

oil had been used, the high-pressure discharge valves became leaky, thus allowing the air to churn in and out of the cylinder at each stroke, and heating it until it became so hot that the heavy deposits in the passages actually took fire; the whole system burned out, like a chimney from an old-time wood stove. Fortunately, however, there was no explosion because the safety valve on the receiver relieved the sudden pressure caused by the burning material in the discharge passages and the compressor was promptly shut down.

From the foregoing it will be understood that in the selection of an oil for air-cylinder lubrication, nothing should be used but a pure mineral product having a gravity of from 31 to 33 Beaumé, a flash point of 375 to 390 deg. F., and a viscosity of 140 to 150 S at 100 deg. F. Under no circumstances should a heavy grade be used, despite whatever claims may be made by the oil salesmen as to the virtues of heavy viscosities or high flash points. It should also be borne in mind that when the surface of the cylinder wall is once glazed over, little oil is required to properly and adequately lubricate the working surfaces.

Too Much Oil Forms Carbon Deposit

The film of oil on the cylinder wall is understood to be less than 0.00025 in. in thickness. The piston rides back and forth on this film, which requires little oil to be added in order to maintain the necessary quantity. Should a greater amount of oil be used than just enough to keep up the required film, it will be plowed up ahead of the piston and be forced through the valves and into the cylinder cavities, where it will collect in the low places and solidify by reason of being mixed with foreign matter taken in through the inlet. This forms deposits commonly called carbon.

As has been shown, a 14 x 14-in. cylinder can be adequately lubricated with two drops of oil per minute when the compressor is operated at 150 r.p.m. This is the equivalent of one drop of oil for each 800 sq. ft. of cylinder surface swept by the piston. The oil herein referred to happened to be made from a paraffin base petroleum. However, it is believed that an oil of about the same consistency, refined from an asphalt base natural oil, would serve as well, if not better.

Soft Coal Exports in May

Exports of bituminous coal in May of this year increased markedly over those of the corresponding month of last year. In the table following the revised figures covering the exports for May, 1917, are given for purposes of comparison. The returns to the Department of Commerce are as follows:

COAL EXPORTS FOR MAY, 1917, AND MAY, 1918

	May, 1917	May, 1918
Anthracite, tons	429,137	425,110
Bituminous, tons*	1,830,439	2,119,700
Exported to (in part):		
Italy, tons	41,139	
Canada, tons	1,401,158	1,766,785
Panama, tons	45,111	50,108
Mexico, tons	12,484	14,181
Cuba, tons	153,750	137,048
Other West Indies	37,282	25,717
Argentina	23,888	14,750
Brazil	44,281	79,400
Uruguay	1,329	4,529
Other countries	70,017	27,182
Coke	134,091	146,740

*Does not include fuel or bunker coal laden on vessels engaged in foreign trade, which aggregated during May, 1917, 629,010 tons and during May, 1918, 425,796 tons.

Minecdotes

The Tendency of the Times

When coal mines first started to electrify their power equipment, the coal operator was practically at the mercy of the equipment salesman. The result was that some mines are a veritable museum of all the kinds of electrical equipment ever built. Today, however, the average coal operator is well versed in matters pertaining to electrical equipment, and a salesman must be equipped with more than the usual line of hot air to obtain any consideration.

An amusing but instructive incident took place a short time ago at a meeting of salesmen and engineers representing several manufacturers of electrical equipment. The object of the meeting was to establish, if possible, some standard ratings as regards speed and capacity of mine equipment. A salesman from one company suggested a questionable method of rating the capacity and speed of mine locomotives, stating that there could be no objection to the method since the customer had no way of making a check. An engineer from one of the other companies immediately jumped to his feet and, pounding his fist on the table, said in forcible language, "Gentlemen, the time has past when you can stick your finger in the customer's eye and when the tears roll down his face make him believe it is raining."

Legal Department

Notice of Condition Imputed to Employee—A mine employee who had passed through an entry 66 times in 11 days must be presumed to have known the fact that the entry was too small to enable him to alight from a car therein, as affecting liability for injury occurring to him while driving an ungentle mule through the entry. (Kentucky Court of Appeals, Mahan Jellico Coal Co. vs. Bird, 201 Southwestern Reporter, 306.)

Authority of Coal Company's General Manager—Holding that the operations of coal-mining companies are such that the general manager of such a corporation may be deemed to have implied authority to contract for the sale of the entire output of his company for a given year, the West Virginia Supreme Court of Appeals said recently in the case of Producers' Coal Co. vs. Mifflin Coal Mining Co., 95 Southeastern Reporter, 948: "A corporation acts only by and through its officers and agents, and Deal was an agent of defendant, held out by it to the public, by virtue of his position, as representing it in the general management of its business, one important feature of which was the sale of the product of its coal mine. Coal-producing companies do not store their coal, but usually sell it before it is mined, and to be delivered at a future time. * * * The general manager of a corporation has authority to bind it by such contracts as are reasonably incident to the management of the business intrusted to him. It was therefore not incumbent upon plaintiff to prove that Deal was expressly authorized to make the contract sued on, in order to hold the defendant liable. His apparent authority, as general manager of its business, to make the contract was sufficient ground to create liability."

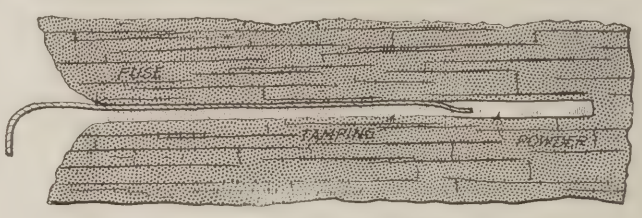
Coal, Explosives, War—II

By H. J. BROUGHTON
Wilmington, Del.

SYNOPSIS—Various methods may be employed for exploding powder or other explosive in boreholes for which both the electric squib and electric primer are entirely satisfactory. Proper placing of shot holes, adequate and careful tamping and prompt detonation are as essential to the best results as is the quality of the explosive.

IN USE, blasting powder is exploded by a spark from fuse, electric squib or miner's squib, or by a primer of some high explosive, the last being employed only in heavy charges on open work. In mining, and sometimes in light charges on open work, blasting powder is made into cartridges by means of a paper tube or cylinder sealed at one end, which is known as a tamping bag. Sometimes the paper cylinder is made by the miner, by coiling a section of heavy paper, known as blasting paper, around a wooden pin, called a cartridge pin, and securing it with what is called blasting soap. The removal of the pin leaves a cylindrical cartridge open at one end, into which the powder is poured, the top being then folded and sealed with blasting soap.

The cartridge form increases safety by eliminating loose powder about the borehole, protects the blasting powder from moisture when in the hole, and makes the charging much easier and quicker.



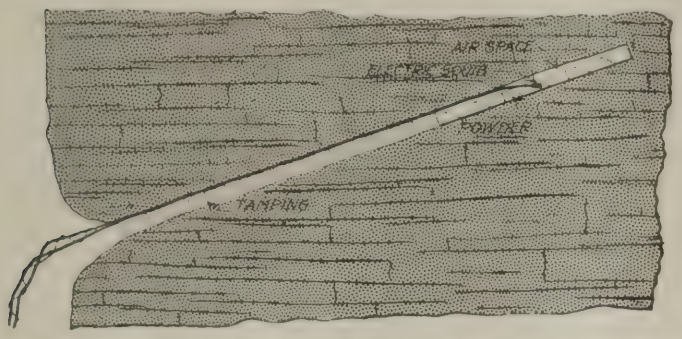
The cartridge pin should be but little smaller in diameter than the borehole so that the cartridges will fit snugly therein without appreciable air space around them. The air space is usually objectionable because it tends to reduce the breaking effect and the results given by the explosive. It is not advisable to make the cartridges longer than 18 in., because they are then heavy and bulky and likely to break or become unsealed in handling. Any length that may be required less than 18 in. can readily be made. One or more cartridges may be used in each borehole.

Best Method of Exploding Cartridges

The best way to explode blasting-powder cartridges is with an electric squib or with a high explosive primer. The latter should not be used in coal mines. Other methods are with fuse, miner's squib, electric blasting cap or delay electric igniter. The electric blasting cap is an efficient blasting-powder exploder, but is no better than the electric squib, which costs less, although when a high explosive primer is employed to explode large charges of blasting powder an electric blasting cap is necessary.

The advantages of the high explosive primer detonated by an electric blasting cap are that it can be lowered into a deep hole and properly placed in the charge more easily than an electric squib, electric blasting cap or blasting cap and fuse; that the flame given off and the heat generated by the detonation of the high explosive primer cause the blasting-powder charge to explode more quickly and therefore to do more work, and that the explosion can be started in the middle of the blasting-powder charge. A blasting cap or fuse may be used for detonating the high explosive primer, but where this is done the advantage gained by placing the primer in the center of the powder charge is lost, because the "side spit" from the fuse almost invariably ignites the blasting powder before the fuse has burned to the blasting cap in the high explosive primer. These are the same difficulties that occur when the blasting-powder charge is exploded by a fuse or squib from the outer end.

In the use of fuse or miner's squibs, the charge cannot be first ignited in the middle. When the explosion of a charge of blasting powder in a borehole commences at the outer end, the gases evolved by the first portion of the powder exploding blow away the resistance, so that the latter part of the charge practically burns in the open and much of its value in breaking the surrounding material is lost. Also, when a long charge begins to explode at one end, the shock of the first part of the explosion may break the outer part of the powder entirely. Or again, the explosion of one end of

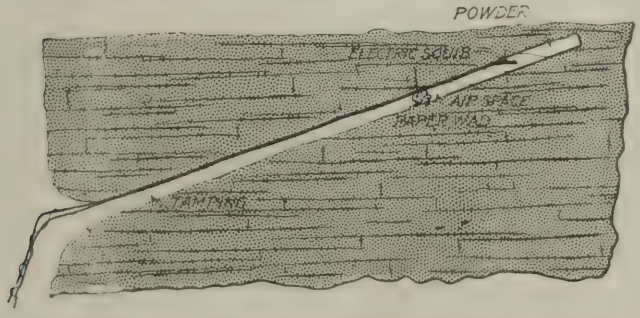


A LOADED HOLE PRIMED WITH A FUSE

the charge before the other may result in throwing partly exploded and burning powder into the open air in places where it might cause disastrous results. It must be understood that the time required for the explosion to travel from one end to the other of even a long charge of blasting powder is short indeed, but a much longer period is required than for the detonation of a high explosive to travel the same distance, and takes enough time to cause the results already described.

Other advantages in the use of the electric squib or the electric blasting cap, either with or without a dynamite primer, are the elimination of smoke from burning fuse and the ability to explode a number of charges simultaneously, which results in greater execution. Furthermore, the shotfirer has absolute control of the time when the shot explodes, making it possible to fire when everybody is in a safe place, thus eliminating the danger resulting from persons inadvertently entering a chamber after a slow-burning fuse has been lighted. Still another advantage in electrical ignition of blasting-powder charges is that the possibility of misfire is reduced to a minimum and that of hangfire entirely eliminated. Misfires, hangfires, and quickfires occur not infrequently with the use of fuse or miner's squibs. Hangfires have probably caused as many accidents as anything else connected with the use of explosives.

When the electric squib is used to explode blasting-powder charges in cartridges, the paper shell already referred to is filled half full of powder, the electric squib put in, and then the remainder of the shell is filled with powder above the electric squib and about the



LOADED HOLE WITH AIR SPACE AROUND CHARGE

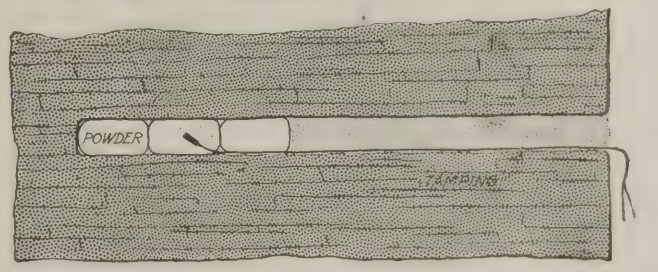
wires. Enough empty shell is left at the top to tie securely about the wires. The cartridge is primed in this manner, and if the charge is to consist of more than one cartridge, this one, known as the primer, is placed at or near the center of the charge.

When exploding bulk charges of blasting powder chambered in boreholes on open work with electric squibs, the squib should be lowered into the borehole after half of the charge has been poured in. The remainder of the charge is then poured on top of it.

To lower the squib into the borehole, a blasting-powder cartridge should be used or a short stick of heavy wood tied to the wires just above the cap. This will supply the weight necessary to lower the squib easily to the bottom of the borehole. Metal or stone or anything else that could strike a spark should not be used for this purpose.

Pushing the electric squib into the borehole with the tamping stick, by spreading the wires just above the cap and catching the loop thus made on the end of the tamping stick while the wires are held taut, should never be resorted to. The objections to this are that the pressure on the wires necessary to hold the electric squib in place is quite likely to break them apart in the cap; the probability of destroying the cap by striking the end of the tamping stick against some projection on the sides of a borehole, made irregular by springing, and the difficulty of withdrawing the tamping

LOADED HOLE WITH AIR SPACE IN FRONT OF CHARGE



stick and leaving the electric squib in proper position in the charge.

An easy way to prime a charge of blasting powder in bulk is to make a blasting-powder cartridge primer with electric squib, as already described for blasting in mines, then lower this primer into the bulk charge of blasting powder. This primer, being heavy, can be readily lowered into place without aid from a weight or the tamping stick in the same manner as that employed with a high explosive primer. If a primer consisting of high explosives and an electric blasting cap be used for exploding a charge of blasting powder in bulk, it also should be located somewhere near the center of the charge.

When fuse is employed for igniting charges of blasting powder in cartridges, it should be tied into the cartridge just as the electric squib is, but it is not necessary to have it extend more than a couple of inches into the powder. If the charge consists of more than one cartridge, the one containing the fuse should be loaded last. The best way to prime a charge of blasting powder in bulk, with fuse, is to tie the fuse into a cartridge and lower it onto the charge.

The miner's squib is employed only in mine blasting and when the charge is in cartridge form. Although the blasting-powder charge is not truly primed with it, the miner's squib is the means of igniting the charge. Accordingly the method of using it will be here described.

When using the miner's squib, the copper-tipped or brass miner's needle is pushed 2 or 3 in. into the end of the blasting-powder cartridge or the outside one, if the charge consists of two or more. The cartridge is then put into the borehole with the point of the miner's

EXPLOSIVE CHARGES SHOULD BE IGNITED AT OR NEAR CENTER

needle remaining in it and the other end of the needle extending from the mouth of the hole, the needle having first been carefully coated with soap. Tamping is then packed tightly about the needle from the charge to the mouth of the borehole.

Careful removal of the needle leaves a hole about ¼ in. in diameter from the mouth of the borehole into the powder. In this hole the miner's squib is laid, with the "slow match" end extending. This is lighted, and when the fire burns to the powder train in the squib, the squib shoots like a rocket back through the needle hole into the powder and explodes the charge.

The miner's squib method of exploding blasting powder charges is the cheapest, so far as first cost is concerned. Besides having the disadvantage of starting the explosion at the end of the charge, like fuse, it is probably the most uncertain method in its result, because if the needle is carelessly removed the hole in the tamping may close up in places and prevent the miner's squib from shooting into the blasting powder.

In order to prevent this, a piece of ½-in. gas pipe, called a blasting barrel, is sometimes used instead of the miner's needle. One end of this is embedded in the end of the outside powder cartridge, while the other end extends from the mouth of the borehole, and the

tamping is packed around it just as when the needle is employed. The blasting barrel is not withdrawn, however, and the squib shoots back to the powder through it, the blasting barrel being thrown out with the material blasted when the explosion takes place. It is then recovered, and sometimes is used a number of times before it is destroyed. This is a much more certain method than the use of the miner's needle, but is almost, if not quite, as expensive as the use of fuse. This, however, depends on the number of shots the blasting powder will withstand.

As a general rule, it is necessary to press the charge compactly into the back or bottom of the borehole and to tamp tightly above it to the mouth of the hole, if the maximum efficiency of the explosive is to be developed. Sometimes, however, in easily shattered coal or other material, greater execution will result if an air space remains around the powder charge, or preferably between the last cartridge loaded and the tamping. The former is accomplished by making the cartridge shells on a pin materially smaller in diameter than the borehole, and not pressing the cartridges so hard in the back of the borehole that the shells will be crushed or break.

How to Provide the Air Space

The air space between the charge and the tamping is provided by pushing a wad of paper back to within several inches of the charge, and then filling outside or above this with tamping material, first pressed lightly in order not to push the paper wad any closer to the explosive. When the explosion takes place the air space back of the tamping acts as an elastic cushion, causing that part of the force of the explosion, which is first exerted forward or upward along the line of the borehole, to rebound and expend itself, to a considerable degree, laterally. This sometimes results in sufficient side-spreading of the explosive force to bring out a great quantity of coal or stone in large lumps, when, without the air space, the charge would expend the major portion of its energy forward or upward along the line to the face or surface, resulting only in blowing out a comparative small quantity. This method of blasting applies principally to coal mining, where it is known as an "air shot."

Charges of all blasting explosives must be closely confined to be effective. This applies particularly to blasting powder, because on ignition it changes from a solid into a gaseous state slowly as compared with most other blasting explosives. It can be easily understood that if there be one or two places in the material confining the charge that are materially weaker than all of the rest, such, for example, as insufficient tamping in the borehole, the gases formed by the rapidly burning powder will blow out through the weak spots, often projecting large quantities of flame with them. "Blow-out" and "windy" shots in coal mines are examples of insufficient resistance to the charge of blasting powder, due to shots being badly located because they are improperly balanced in resistance.

These arise from overcharges of powder when the resistance in several directions is not great enough, and to insufficient tamping, which permits a large part of the force of the explosion to waste itself through the borehole. As the gases given off by a partly tamped charge are much more poisonous than those from a thoroughly tamped one, the desirability of filling the hole to the face with tightly packed material can be readily understood.

The best tamping material is damp clay, free from pieces of stone. Sharp scraps of stone in the tamping are likely to cut or abrade the fuse or the insulation of the electric squib or the electric blasting-cap wires. Coal dust is poor tamping, not only because the heat generated by the explosion burns it, but also because it does not pack well. Tamping bags are recommended as containers for the tamping used in all horizontal or pitching boreholes and in "uppers." It is practically impossible to tamp uppers and difficult and inconvenient to tamp horizontal or pitching boreholes without containers for the tamping. If regular tamping bags are not at hand, cylinders for this purpose should be made out of paper, like those used when making the powder into cartridges.

For pressing the tamping into the borehole a tamping stick is used. This is a straight rod of hard wood, a little smaller in diameter and a few feet longer than the borehole. There must be no metal whatever about it. It is absolutely unsafe to use a drill or any metal bar

PROPER PLACING OF ELECTRIC SQUIB

to tamp any explosive. This is particularly true if the explosive be blasting powder. When metal comes forcibly in contact with rock, or even with sand or any other very hard substance, it may strike a spark, which would easily ignite any grains of blasting powder that it might fall upon. Loose grains of blasting powder are often distributed along even those boreholes in which the powder charge is in cartridges, although an attempt may have been made to fold down and seal the ends of the cartridge shells. A few grains of powder would quickly carry the explosion from the grain accidentally ignited by a spark to the charge proper.

Dangerous to Use Metal in Tamping

In vertical boreholes through rock which have been chambered, the walls are nearly always more or less ragged and seamed, with ledges and points. When the borehole is charged the powder lodges on these, and even a wooden tamping stick must be used carefully to avoid knocking together two pieces of hard rock with sufficient force to throw a small spark into the powder. For tamping in this work it is exceedingly dangerous to use a metal bar, a pipe with wooden plug in the end, a wooden stick spliced with nails, wire or tin or anything that has any metal whatever about it.

The first 3 or 4 in. of tamping should be dry and pushed gently against the powder. The remainder ought to be packed in with as much force as can be given to the tamping stick used by hand, but particular care must be taken not to kink, cut or abrade the fuse or the wires of the electric squibs or electric blasting caps. When the tamping is not packed tightly to the mouth of the borehole a part of the force of the blasting powder is wasted. The electric squib wires, electric blasting-cap wires or the fuse must always be long enough to extend well out of the mouth of the borehole.

(To be concluded)

Testing for Gas in Mines

By H. E. GRAY
Confluence, Penn.

SYNOPSIS—*Crude practice of firebosses, in testing for gas in mines. Choice of a suitable lamp for testing. Important features and requirements. Principle of all safety lamps. The lamp flame, its formation, size and quality. Flame caps; the "fuel or oil cap" often mistaken for a gas cap when the lamp burns a volatile oil. The "Sight Indicator" for reading percentage of gas present avoids guesswork and brings all firebosses' reports to the same base of measurement, which is important in testing and reporting gas.*

MANY men have given their time and attention to ideas, schemes and suggestions from which might be formulated some fixed method or plan to guide the fireboss or mine examiner in doing his work, enabling him to obtain positive results and eliminate the fatal guesswork in determining the gaseous condition of the mine air.

In his splendid work on "Mine Gases and Explosions," J. T. Beard says, in describing the method of measuring gas in the mine, page 345, "Strange as it may seem, the common practice of determining and reporting the quantity of gas found in a chamber is even more crude than the method of its detection."

It is evident to all acquainted with the work that the methods commonly used in mines to-day, for testing gas, are strangely in keeping with the rule of "By guess and by gosh." *By guess*, you are right; but *by gosh*, you are wrong. If we would avoid the pitfalls of the past and cut out all guesswork in gas testing, we should begin by selecting a suitable lamp.

The lamp must be constructed on principles that will enable a fireboss to make a satisfactory test for gas, under the varying conditions existing in mines. Whether the mixture is explosive or inexplosive, one must be able to make the test safely and withdraw his lamp without losing his light. The extinction of the lamp would seriously interfere with the completion of the work within the time allowed by law.

While other firebosses may prefer lamps of different types, my choice is a lamp of the Marsaut pattern. In order to secure a steady fixed flame, it is important that all inside dimensions shall be such as to avoid any offset or projection on the inner surface of the lamp chimney. The lamp must be bonneted so as to strengthen the motive column formed within the chimney, as that will greatly improve its illuminating power, which is an important feature in the work of examining a mine.

To the student of mining, the term "safety lamp" is misleading, and many miners, even, are prone to think that such a lamp is safe under all conditions. But, in truth, the so-called "safety lamp" is only safe when in the hands of a competent man.

The construction of the lamp is such that its flame is isolated from the atmosphere surrounding the lamp chimney. The gas-charged air enters the combustion chamber and burns within the lamp, but the flame of the burning gas is prevented from passing out by the cool wire gauze forming the chimney.

The principle of the cooling effect of wire gauze on flame was discovered by Sir Humphry Davy. He found that as long as the wire gauze is kept clean and cool, flame will not pass through the mesh of the gauze, unless propelled by a strong current of air. It is important that anyone handling a safety lamp should be acquainted with these facts.

As shown in Fig. 1, an ordinary lamp flame has three zones. The inner zone *A* is dark, being filled with the vaporous and solid combustible matter distilled from the oil drawn up in the wick. No air has reached this zone and no combustion is taking place in it. The next outer zone, marked *B* in the figure, is the zone of

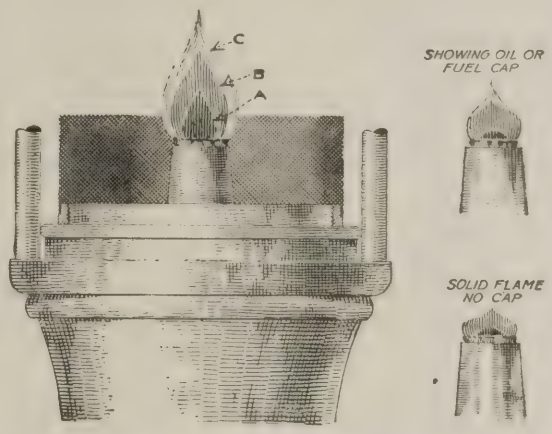


FIG. 1. SECTIONAL VIEW OF PART OF TESTING LAMP

incandescence, where the combustible solids, vapor and gases mixed with air are being consumed. The supply of air to this zone, however, is not sufficient for complete combustion and the combustible matter is rendered incandescent. The outer zone, marked *C*, is nonluminous, the combustion here being complete owing to an excess of air.

In testing for gas, the lamp flame should have the appearance of being glued to the wick, so to speak. It should be a steady, tenacious flame, with a clearly defined outline. Three features must be considered; namely, the size, brilliancy and quality of the flame used for testing.

The *size* of the flame will depend largely on the height of the wick, the kind of oil burned, and the supply of fresh air. The *brilliancy* of a flame interferes with the delicacy of the test and, for this reason, when desiring to make a test, the wick should be drawn down until the flame is only about ¼ in. in height and is nearly nonluminous, as illustrated in the lower right-hand corner of Fig. 1.

The *quality* of the flame is an important factor in making a test and depends chiefly on the fluid burned in the lamp. A light, volatile oil, such as naphtha, benzine or gasoline, gives a more brilliant and less tenacious flame than sperm or cottonseed oil. For this reason, the last

mentioned oils are much to be preferred for the purpose of testing for gas.

Either sperm or cottonseed oil gives a solid flame that is not readily extinguished when proper care is taken. The products of combustion when these oils are burned form a more extinctive atmosphere in the top of the lamp chimney than when a volatile oil is burned. This tends to reduce the force of an explosion should one occur within the lamp, which is thus rendered less liable to fail in gas.

On the other hand, if a light volatile oil is burned the tendency of such oil to vaporize under the heat of the lamp generates an inflammable vapor more rapidly than it is consumed, and materially increases both the force of a possible explosion within the lamp and the chance of failure of the lamp in gas.

The flame of a lamp burning a volatile oil is surmounted at all times by a faint halo. This, as shown in the upper right-hand corner of Fig. 1, has been termed an "oil or fuel cap." In a few instances, I have known gas to be reported by the mine examiner when there was no gas present, the examiner being deceived by the oil cap on his flame. In the use of a heavier oil, as sperm or cottonseed oil, no oil cap is formed and there is no opportunity for the fireboss to be deceived.

I have mentioned the fact that there should be no interior offset or projection in the lamp chimney. A smooth surface gives a greater rigidity or fixedness to the lamp flame. A surface that is not uniform may cause a slight sidewise motion of the flame, which might be taken as an indication of the presence of firedamp. The same effect may be caused by the conflict of ascending and descending currents, in the combustion chamber, when air is permitted to enter the lamp at a point above the flame.

In regard to the wick I much prefer a flat to a round wick. It should be a little wider than the wick tube, so that when completely saturated with oil it will be self-sustaining. When inserted in the lamp, the wick should be perfectly dry and just long enough to reach the bottom of the oil vessel. A short wick, frequently renewed, will give much better results than a longer wick used for some time. The latter is apt to become gummed and clogged so as to prevent the flow of oil to the flame.

To insure a more uniform flame and better illumination, a flat wick tube should be corrugated. The pricker should be so arranged as to sweep over the full width of the wick tube. It should operate at a slight angle with the top of the tube. To prevent extinguishing the flame, the crust should be sheared from the top of the wick, at one end first. The flame should then be allowed to ignite that end before shearing the crust from the other end of the tube. The pricker should work easily and yet not be so loose that it will fail to maintain its position when raised and turned.

The bonnet is one of the chief features in the construction of a good testing lamp. It serves as a chimney, affording a fixed inlet and outlet of the air and gases circulating through the lamp, whereby a good motive column is maintained within the chimney.

I have now described what have seemed to me to be the more important features of a good testing lamp. There only remains to consider some means that will enable a fireboss to measure correctly the height of the flame cap he observes when the lamp is raised into a body of gas. The simplest and most certain means of determining the percentage of gas indicated by a given height of flame cap is that designed some years ago by Messrs. Beard and Mackie, and known as the sight indicator. This device, shown on the right of Fig. 2, consists of an upright standard secured firmly to a circular disk that fits over the wick-tube in a safety lamp. As shown in the figure, seven platinum wires are mounted on this upright. The lower or standard wire is straight, while the upper percentage wires are looped at the center, which enables them to be more clearly seen and not confused with the wires of the gauze chimney of the lamp. On the left of the figure, the device is shown inserted in a common Davy lamp, which is the favorite lamp with firebosses, in testing for gas.

In the use of the sight indicator, the height of the flame is so arranged that the lower standard wire shows a slight incandescence in fresh air. When the lamp is then exposed to air containing gas, the percentage of

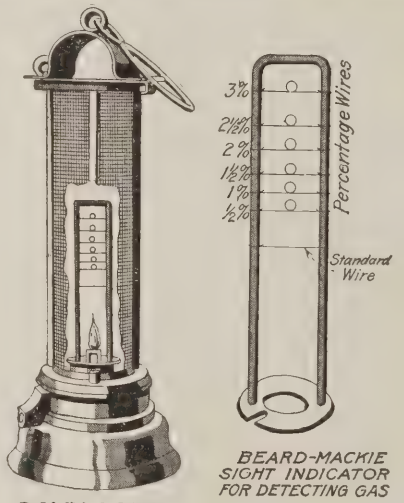

FIG. 2. TO MEASURE PERCENTAGE OF GAS IN AIR

gas present is indicated by the incandescence of one or more of the percentage wires. The uppermost one of the wires thus incandesced marks the percentage of gas present.

For example, if two of the loop wires are incandesced there is 1 per cent. of gas present; but if the third wire also shows an incandescence there is 1.5 per cent. of gas, etc. Should all the wires show incandescence, there is at least 3 per cent. of gas present in the air, and steps should at once be taken to avoid disaster, owing to its possible ignition. When between 4 and 5 per cent. of gas is present the lamp will generally fill with flame and must be promptly though cautiously removed from the body of the gas.

The sight indicator is the most accurate and speedy means of detecting the percentage of gas present in mine air that has been devised and should be used by all firebosses, in order to standardize their reports and bring these to the same basis of measurement. This is very important in reporting gas found in the air splits circulating in the different sections of a large mine. In testing for gas with this indicator, the incandescence of the wires reduces the danger of an explosion occurring within the lamp's chimney, and renders the lamp flame less liable to extinction.

Mine-Car Axles

By B. P. LIEBERMAN
New York City

SYNOPSIS — *The suitability of iron or steel for use as mine-car axles depends upon both its chemical analysis and physical structure. A steel of proper analysis may be improved for use as an axle by mechanical working or by proper heat treatment. This latter method is rapid, positive and under easy control.*

A FAMILIAR sight around some coal-mine repair shops is the large number of discarded mine-car axles. Some of them are bent or broken, while others are excessively worn at the journals. Some of these axles doubtless failed in service, causing a wreck somewhere along the haulageway. The discarding of these axles is in itself an item of expense, but far more serious is the delay in production caused by wrecks and the necessary repairs, not to mention the element of danger to the miners.

Why do axles fail, and why is not something done to eliminate failures of this kind? Axles fail on account of overload or abuse, or they may be made of material unsuitable for the purpose. Their failure is often considered a necessary evil and something that cannot be avoided. Some mine operators try to remedy the difficulty by replacing such axles with ones of larger diameter. Such a procedure is quite expensive, as it affects also the wheels and axle boxes and in addition materially increases the dead weight of a mine car.

Coal-mine operators are bound to have trouble with their mine-car axles as long as they continue to specify in their purchase orders just "axles." If they follow this practice, they do not know whether they get an axle made of wrought iron, a poor grade of steel or a steel too low in carbon. It is evident that one kind of steel must be most suitable for the purpose. This kind does not necessarily have to be the most expensive material.

The Proper Size of Axle

An axle is properly proportioned when it is capable of standing the load to which it is subjected without being permanently deformed and with a reasonable margin of safety to take care of extraordinary conditions. In addition, the material must be such that the axle performs under these conditions without showing undue wear at the journals and without being affected by fatigue or crystallization, which would cause it to break unexpectedly and before it has given full service.

The ability of an axle to withstand bending action is proportional to its cross-section and to the allowable working stress of the material from which the axle is made. The working stress is the ultimate tensile strength divided by the factor of safety.

The figures in Table I illustrate plainly the difference which exists between the different materials from which mine-car axles may be made.

Table I shows that the strength of different grades of steel varies between wide limits. In other words, of two mine-car axles of the same diameter, and alike in all respects except material, one axle may stand four or five times the load which the other one will endure, and this in spite of the fact that the axles look exactly alike from the outside.

In the table, as will be noticed, the different kinds of steel are listed simply according to the amount

TABLE I. DIFFERENCE IN MATERIALS ENTERING INTO THE CONSTRUCTION OF MINE-CAR AXLES

Material	Ultimate Tensile Strength, Lb. per Sq.In.
Wrought iron	45,000
Low carbon steel, about 0.08 per cent. C	55,000
Low carbon steel, about 0.20 per cent. C	65,000
Medium carbon steel, about 0.30 per cent. C	75,000
Medium carbon steel, about 0.50 per cent. C	90,000
Nickel steel, 3½ per cent. nickel	100,000
Heat-treated steel	110,000 to 230,000

of carbon which they contain, and no reference is made to such names as machinery steel, openhearth steel, axle steel, etc., under which designation the material of axles is sometimes familiar to mine operators. The figures in the table show plainly that it is mainly the amount of carbon which controls the properties of the steel, and therefore such general names as machinery steel, etc., are meaningless and misleading.

Even such material as cold-drawn or cold-rolled steel may possess properties varying between wide limits unless the amount of carbon is specified. Cold working, as will be shown further on, improves the physical properties of steel to a certain extent. As far as cold rolling is concerned, this process is little used at the present time, and steel which goes under this name is cold finished either by cold drawing or cold turning and polishing. The cold-drawn grade is used in the smaller diameters of axles or those up to 2 in., as well as the lower carbon steels, while the cold turned has been supplied for larger diameters and higher carbon steels above 0.25 per cent. C.

The fact that the hardness of steel increases in the same proportion as the ultimate strength, as given in Table I, has been utilized for testing purposes. By means of a simple testing device the surface hardness is measured, and this bears a direct relation to the physical qualities of the material.

It is customary to designate hardness either by Brinell number or by scleroscope number. The Brinell instrument forces a steel ball of standard size under a standard load into the metal under test. The Brinell number then equals the pressure on the ball in kilograms divided by the area of indentation surface in square millimeters. In this test the diameter of the steel ball is 1 cm., the pressure on the ball is 3000 kg., the area is determined by measuring the diameter of the indentation with a microscope and by reading from a table the corresponding hardness number.

With the scleroscope instrument, hardness is indicated by the rebound of a small steel weight with a diamond tip from the surface of the test piece. The weight is allowed to fall about 10 in. and the distance it rebounds is taken as a measure of the hardness of the sample. A scale is provided which is divided into 140 equal parts, and the hardness is expressed

FIGS. 1 TO 5. MICROPHOTOGRAPHS OF THE CROSS- SECTION OF IRON AND VARIOUS STEELS

as the number on the scale to which the weight rebounds.

It should be remembered that the scleroscope number in itself does not mean anything at all. It is simply a means for comparing the hardness of different grades of steel and for specifying the hardness desired for a certain axle or other part. With the Brinell instrument the hardness number is an absolute value, expressing kilograms per square millimeter which the metal withstood. Table II gives the average hardness number of a few grades of material used for axles.

One property of steel which must be considered is its ductility. Ductility is measured by the amount a steel elongates or stretches before breaking. The more brittle a steel, the less ductility it possesses. A certain amount of ductility is required to make an axle stand up under shocks, and with an increase in hardness the ductility rapidly decreases. This is the reason why, for instance, an axle after heat treatment has to be drawn or tempered. This naturally decreases its hardness; but it has to be done as otherwise the axle would be hard, like glass, and would snap off when running over rail joints or switches.

TABLE II. AVERAGE HARDNESS NUMBER OF DIFFERENT MATERIALS

Material	Hardness Number—Brinell	Hardness Number—Scleroscope
Wrought iron	85	13
Low carbon steel, about 0.08 per cent. C	110	16
Low carbon steel, about 0.20 per cent. C	125	19
Medium carbon steel, about 0.30 per cent. C	150	23
Medium carbon steel, about 0.50 per cent. C	175	27
Nickel steel, 3½ per cent. nickel	200	30
Heat-treated steel	220 to 460	33 to 69

Steel may be considered primarily as an alloy of iron and carbon, and while it always contains impurities which have some influence on its physical

properties, carbon is its most important ingredient and regulates and controls its chief qualities. Pure iron is extremely soft, very ductile and of low tensile strength.

Besides carbon, other elements are sometimes introduced into steel, such as nickel, chromium, vanadium, etc. Such additions are desirable either on account of their deoxidizing power or because they improve the physical properties of the steel. For mine-car use nickel steel is perhaps the best known of these alloys. Nickel imparts to steel a high elastic limit and great toughness under shock.

Structure Is As Important As Analysis

The composition of steel can be determined by chemical analysis, but its structure or anatomy can be ascertained by the use of the microscope. Chemical analysis calls for the complete destruction of the anatomy of the steel; micrographic analysis is based on the anatomy itself. In the microscope a highly effective tool is placed in our hands for observing with our own eyes the structure of the different kinds of steel in their normal condition, as well as to observe the effect of heat treatment and mechanical working, such as cold rolling. Looked at under the microscope, light and dark particles can be distinguished. The light spaces show the crystalline grains of carbonless iron or free ferrite, while the small dark masses contain the carbon in the form of carbide of iron, together with some iron. No pure carbon ordinarily exists in steel in the free state. The dark masses are called perlite. The perlite possesses considerable hardness and is therefore more desirable than the ferrite. On account of its softness the ferrite wears off quite rapidly.

Fig. 1 shows a sample of wrought iron which is representative of the material put into wrought-iron axles. The absence of dark spots proves that there are no more than traces of carbon contained in wrought iron. The dark bands are slag, which gets into the wrought iron during the process of manufacture. The absence of carbon makes wrought iron extremely soft, while the layers of slag cause it to flake off at the journals.

Fig. 2 shows a sample of low-carbon steel which was taken from an axle that failed. This piece of steel contains about 0.10 per cent. carbon. Such an axle will soon become rough at the journals and will rapidly deteriorate. This is exactly what happened in this case.

Fig. 3 shows a sample of steel containing 0.40 per cent. of carbon which was taken from the surface of a hot-rolled steel axle that stood up without excessive wear. The larger percentage of carbon is clearly illustrated by the increased number of dark masses.

Fig. 4 shows how an axle looks which contains the same amount of carbon as that shown in Fig. 3, but which has been subjected to a process of mechanical working, such as cold drawing or cold rolling. This process has broken up the particles and has caused a finer structure, particularly on and near the surface, where the effect of rolling is most pronounced.

A much finer structure than it is possible to secure by mechanical working can be obtained by heat treating. It is a peculiarity of steel that it changes its structure when heated to a certain temperature. When this change is arrested by quick cooling, such as quenching, the fine structure is retained.

Fig. 5 shows a sample of the same axle as shown in Fig. 3, but after heat treatment. The constituents are now so thoroughly intermixed that it is hard to distinguish the individual particles any longer. Such an axle necessarily possesses a considerable degree of hardness, depending chiefly on the amount of carbon.

Inasmuch as the amount of carbon contained in wrought iron and low-carbon steel is negligible, it is obvious that neither wrought iron nor low-carbon steel can be hardened appreciably.

No picture of nickel steel is shown; it would look somewhat similar to Fig. 5. Such steel, with proper heat treatment, is practically a homogeneous mass showing no grain or fiber. It has a somewhat better wearing quality than carbon steel and possesses extraordinary power to resist shocks.

The process of heat treating is quite simple, and comparatively little equipment is needed for the various operations: a furnace, whose temperature can be regulated, a pyrometer for measuring temperatures and a tank with oil for quenching.

An axle with a carbon content of about 0.45 per cent. would, for instance, have to be treated as follows: Heat from 15 to 30 minutes at 1490 to 1510 deg. F., quench in oil, reheat for 30 minutes at 400 deg. F. and cool in air.

Ductility Is Secured By Tempering

The first treatment produces a hardness that would be far too great for mine-car service. The axle is therefore tempered somewhat to obtain sufficient ductility. This is accomplished by the second treatment. The higher the reheating temperature is made the softer the steel will be. A reheating temperature of 400 deg. F. produces a hardness of about 300 Brinell (42.5 scleroscope), while a reheating temperature of 800 deg. F. would produce a hardness of about 25[illegible] Brinell (37.5 scleroscope). Compare this with the hardness of the axle in its original condition, which was about 170 Brinell (26 scleroscope). In other words, the heat treatment has raised the tensile strength of the steel from about 85,000 to about 150,000 lb. per square inch in the first case, and to about 125,000 lb. in the second case. In addition, the particles in the steel have been so thoroughly intermixed as to offer the greatest possible resistance to wear on the journals. A hardness of approximately 250 Brinell has been found ample for the severest requirements of mine-car service.

An axle does not necessarily have to be heat treated throughout its entire length, but only on the points where breakage or wear are most liable to take place, which is on the ends. This method can be successfully carried out with a much smaller heat-treating equipment.

A heat-treated axle, therefore, has quite an advantage over ordinary axles and is desirable for the following reasons:

1. It has many times the strength of an ordinary axle. The chance of bending or breaking in service is comparatively remote.

2. Its ductility, if properly tempered, is sufficiently great to make it withstand the shocks and abuse of ordinary mine service.

3. On account of the thorough intermixing of the carbon with the iron, the wear at the journals is negligible without necessarily causing additional wear in the wheel hubs or bearing boxes.

The advantages to be derived from heat-treated axles for mine cars were not appreciated until a few years ago, when the ever-increasing demand for greater load capacity, for greater speed and quite often for longer trips, set up a demand for better axle material. The advantages arising from their use is well illustrated by the experience of a prominent producing company which stated that "before using heat-treated axles, we sold about a car and a half of scrap axles every year; but since using heat-treated axles we have not sold one in seven years."

Generally speaking, it is preferable to utilize heat-treated axles from the standpoint of ultimate life and freedom from possible failures. But under net loads of from 1 ton to 3½ tons of coal, cold-turned and polished axles of 0.40 to 0.50 per cent. carbon content have been used successfully. The use of the untreated axles must, however, be fully reconciled with the load on the bearing surfaces, as the lack of a suitably hard wearing surface superinduces disastrous wear.

The use of any kind of an axle is an engineering problem that should be submitted to the mine-car manufacturers or other specialists for their approval. Such a course will tend to bring about greater economies in many directions.

Axles Should Be Made of Proper Material

All these qualifications which a successful axle should have apply equally well to mine cars equipped with ordinary plain-bore wheels or boxes, as well as to cars equipped with flexible roller bearings. While the life of axles in connection with plain bearings would be considerably increased if they were made of proper material, a combination of the same axles with flexible roller bearings would last practically forever if reasonably well housed and taken care of. The rollers of these bearings operate directly on the surface of the journals without an extra sleeve, and the axles in such cases have been found neither to bend, break, nor wear down at the journals.

As the advantages of heat-treated, alloy and higher carbon axles are becoming better understood and appreciated, the demand for such axles is rapidly increasing; and several axle manufacturers have installed the equipment necessary to furnish such axles of first-class quality at short notice. As far as the size of the axles—that is, their diameter—is concerned, the following dimensions are generally preferred:

Capacity of Mine Car Tons	Size of Axles at Bearing Seat in Inches Bituminous	Anthracite
1	2	
2	2¼@2½	2⅜
3	2½@2¾	2⅝
4	3	3
5	3	3

In the majority of bituminous mines the bearings are located in the wheel hubs, while in the anthracite region and portions of the bituminous fields it is standard practice to use inside or outside self-aligning journal boxes. In the latter case the axles are usually ¼ in. in diameter, larger in the middle than at the wheel and bearing seats, thereby giving additional strength through increased cross-sectional area.

Central Pennsylvania Miners Go "Over the Top"

The production of coal in central Pennsylvania for the week ended July 13 has exceeded the production for any single week in the history of central Pennsylvania. The officers of the United States Fuel Administration and the Central Pennsylvania Coal Producers' Association are jubilant at the showing made for this period. They state that the figures are beginning to show the results of the campaign to increase the production of coal launched by the Central Pennsylvania Coal Producers' Association several weeks ago.

During the week ended July 13 central Pennsylvania produced 1,327,500 tons of coal. During the week ended July 6, 854,613 tons of coal were produced. This was the week of the Fourth of July. The week ended June 29 was a full week. The production was 1,142,420 tons, or an increase over the week ended June 29 of 185,080 tons. In this manner the miners are attesting their loyalty and patriotism to their country.

Central Pennsylvania being one of the most important fields in the United States, this increase in production of coal will be heartily welcomed by the United States Fuel Administration officials at Washington.

Rembrandt Peale, of the United States Fuel Administration, on a recent visit to Altoona, stated that it is the wish of the United States Fuel Administration that the mining towns, if possible, hold all their celebrations of the great victories of the American and French armies over the German armies in the evening, to the end that the production of coal may not be hindered at this most vital moment of the war and that the armies in the field may be kept in the supplies, guns and munitions necessary to continue the offensive to its conclusion —the absolute and complete defeat of the German armies. In other words, celebrate by increasing production rather than by cheers.

The splendid coöperation of the international officials of the United Mine Workers of America, President Frank J. Hayes, Vice President John L. Lewis, together with many district and local officers of that organization, is chiefly responsible for the wonderful showing, and where the miners and operators have not taken up this proposition seriously this showing should be an inspiration to them of what can be accomplished and their duty in the premises.

The Central Pennsylvania Coal Producers' Association states that the goal set for central Pennsylvania, namely 1,300,000 tons production per week, has been exceeded and the figures raised to 1,400,000 tons.

Teamwork Between the Engineer with his theoretical training and the mine foreman with his practical experience would obtain the maximum success. In a great many cases the success or failure of the mine hangs on the teamwork of these two men. Ofttimes the engineer looks down on the suggestions of the mine foreman, thinking his lack of theory does not give him the proper view of the situation, while the mine foreman thinks the engineer too theoretical. The engineer should temper his theory with the mine foreman's practicability, and vice versa, to obtain the best results.

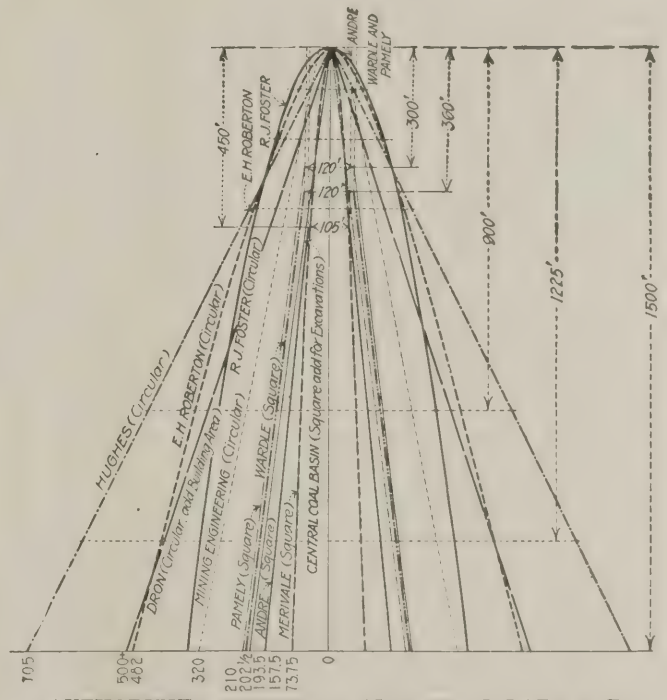
BOOK REVIEWS

A Comprehensive Work on Mining

MINING ENGINEER'S HANDBOOK—Written by a staff of specialists under the editorship of Robert Peele, Professor of Mining Engineering in the School of Mines, Columbia University. Pages X + 2307 + 98 index; 4½ x 7¼ in.; adequately illustrated. John Wiley and Sons, Inc., 432 Fourth Ave., New York City, publishers. Flexible Fabrikoid binding. Price $5 net.

In quality and quantity of material, "Peele's Mining Engineer's Handbook" stands probably first among all the books on mining in general, especially technically and in relation to metal-mining costs. It is a worthy companion of the handbooks of Trautwine, Merriman, Fowle, Kent, Marks and Kidder, in kindred engineering fields. Its aim is, of course, to cover every phase of mining. Coal receives a place somewhat larger than that afforded other minerals, but not the place which would be given to it, of course, in a volume with a less extensive scope.

However, after all, the differentiation between the work in the coal mining and other fields has been largely the cause of the slow advance in both. There are so many likenesses between metal mining and coal mining that we cannot conceive anything which would make more definitely for scientific progress than for engineers in the two branches to replace one another for a few years.



The engineers of each form of mineral are separated locally and industrially. They solve their problems separately. They resolutely contend that the solution of a problem in one line of work would be impossible in another line. They rarely study one another's methods and problems. A book like the one under consideration brings the two realms of mining together. Wider apart than two separate nations in their methods of work, here is a chance for one to learn from the other.

When one looks at the 2307 pages of fine typed material —for there is that number without the index—when one notes how important are all the subjects treated and how condensed is their treatment, one feels little disposed to regret that something is omitted. No one will contend that "Geological and Mineral Deposits," so ably reviewed by J. F. Kemp, professor of geology at Columbia University, did not deserve many more pages than forty, of which coal itself has but two or three. There is room, however, for little more than general principles, and the reader may be assured that what is spared in this department gives space to strengthen all the rest. After all, geology is so varied as to be local, and to study it rightly one must have a local interpreter.

The principles of earth excavation, explosives, rock excavation, tunneling, shaft-sinking, boring and even prospecting, development and exploitation of mineral deposits are more general. They have an appeal as universal as mining. If any systems are peculiar to any one industry—and they are good systems—there is some reason to believe that it is a reflection on the progress of coal mining or some other form of mining that they have not been introduced there under the special conditions likely to be favorable to their use.

The traditions of mining are hard to break. They are the outcome of special environments, conditions and sociological necessities, and being long established they rule us and not we them. We put new men into the field, but we first train them into the ways of the region and into the system of the special branch of the industry to be entered. Eventually, these would-be innovators become obsessed with the fear of the past. They hesitate to break the tradition by following the lead of men in another branch of the industry or in another field, even when they recognize that the men in these other fields are facing similar problems. Other matters treated in Peele's handbook and having a somewhat common application to all forms of mining are underground transport, hoisting plants, shaft pockets and ore bins, mine drainage and ventilation, compressed-air plants and electric power for mine service.

Much has coal mining done to improve transport in metal mining, and in return shaft pockets that originated in the metal mines are now almost the latest thing in coal mining. Many coal operators are already wondering if the mine car has to be hoisted on a moving scaffold to the dump when a skip will do the work as well and a pocket will aid to make the work continuous, and some are not only wondering, but are preparing to hoist in skips. In recalling the indebtedness of the two branches of the service to one another, it may be noted that ventilation has almost been invented and patented by the coal mine. The metal mines hung far behind, as if they did not want to infringe. Even the flexible conduit as a mine device came to light in the coal mines, but it appears to have had its most wonderful development in the metal-mining industry, due largely to

AUTHORITIES DIFFER ON SIZE OF PILLARS FOR VARYING SHAFT DEPTHS

the lack of due appreciation in the industry which first welcomed it and for which it has an almost unlimitable field of usefulness.

Other sections of the handbook being reviewed cover surface and underground surveying, mine geological maps and models, mine organization and accounts, mining costs, wages and welfare, mine air, hygiene, explosives and accidents, mining law, mine examinations, valuations and reports, aërial tramways and cableways, mechanical conveyors, ore dressing and sampling, assaying, ore testing, purchasing and treatment, gold amalgamation and cyanidation, mathematics and mechanics, chemical notes and tables, hydraulics, engineering thermodynamics, steam engines, boilers, pumps, turbines, gas engines and accessories, electric engineering, structural design, mineralogy and tables.

Purposely we have omitted the preparation and storing of anthracite "coal" by Paul Sterling and the preparation and the storing of bituminous coal by H. McKean Conner, both interesting presentations of the problems presented.

Protest may be made against the persistence with which A. M. Bateman in this volume, and other writers in other places, have clung to the questionable theories of subsidence promulgated by earlier writers. A little concession is found in the illustration 548, on page 738, but how futile it is to put the tensile stresses at the edge of the pillar. If the pillar gives at its edge (and what pillars will not do so?), pillar and roof will remain in contact, the pillars rounding to conform with the undulations in the roof. The main bend, and therefore the tension, will be back over the pillar and not at its edge. True we have to the contrary the illustrations of "main break" and "after break" perpetrated by the unimaginative Hausse (see Fig. 559), and the illustration of fracture normal to bedding of Callon (see Fig. 560). But sometimes it is impossible to bow to authority however profound.

Nothing is said about real arching and doming in the pages on subsidence. The only reference to be found is to the pseudo-arches of the early textbooks. Mysterious indeed is the disposition to ascribe to the roof of the underworld laws peculiar to itself. As in the days of Kirchner, theorists can imagine anything in a mine. But after all the roof after being separated from the top of the coal seam is an elastic beam, or rather plate, and this when broken forms an arch, or rather a dome. That the marvelous sketches on pages 732 and 743 can still find their way into scientific treatises shows how a subject not yet looked upon as economic and therefore vital to business success can continue to be misunderstood.

It may be added that Fig. 562, on shaft pillars, is full of errors both of scale and fact. Moreover, part of it is based on an assumption of coal thickness which assumption is not stated. The subsidence pages are merely digests of the well-known Young and Stoek bulletin on that subject. Our illustration on the preceding page shows a diagram of the shaft pillars proposed by the various authorities for different shaft depths. It is based, where the coal thickness is regarded as a factor, on a seam 9 ft. thick.

Key to Recent Engineering Literature

ENGINEERING INDEX FOR 1917—Compiled from the Engineering Index, published monthly in "Industrial Management" during 1917. Pp. 360. 6½ x 9½ in.; no illustrations. The Engineering Magazine Co., 6 East 39th St., New York City, publishers. Cloth boards. Price, $3.

Engineers rarely see more than just a few journals and technical publications, and so a great deal of engineering development passes them unnoticed. Moreover, the articles that they glance over and regard as unimportant today may seem tomorrow indispensable to fill needs that have changed. In consequence, all engineers must depend on the work of the patient cataloguer, who keeps them in touch with the advances of the times and tells them just where they can read about the progress of any special line of engineering endeavor.

To those who live where libraries are not (and most mining engineers are thus circumstanced) there is always the opportunity of getting articles photostated and translated at a reasonable figure by the library in the Engineering Societies' Building, 29 West 39th Street, New York City. Service such as this makes a book like the "Engineering Index" extremely valuable. Just at present left-over copies are not numerous, and the collector of such copies for resale is perhaps not over-stocked; but still there are a few such men and their services can be drawn upon at a figure that discounts even the photostat. For this reason, it is interesting to note that, as far as is possible, the Engineering Magazine Co. is prepared to perform this service to the great advantage of industry.

The Index classifies the articles on current technical literature appearing in some 25 publications published by 17 nations and colonies and in six languages. About three-fourths of these journals are printed in English, the others being principally French, Spanish, Italian and Dutch. There are no German references, except as found in a Zurich paper, the *Schweizerische Bauzeitung*.

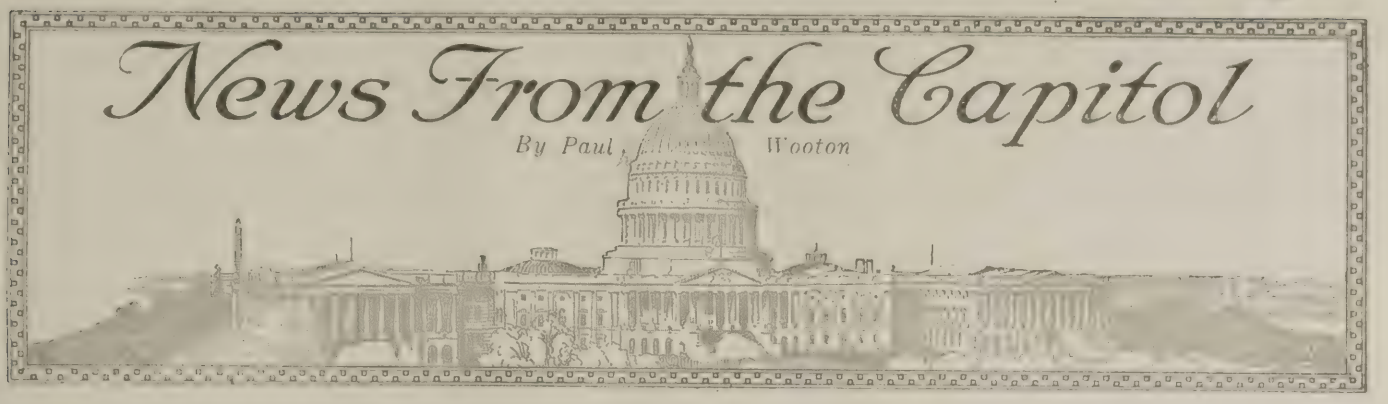
Many of us seeking enlightenment are asking our neighbors where we can get information. This volume gives, for the year 1917, complete and ready answers to our questions.

Developments of the Granby Consolidated Mining and Smelting Co. on Vancouver Island

By R. Dunn
Victoria, B. C.

In view of the position in which the Granby Consolidated Mining and Smelting Co., Nanaimo, B. C., finds itself through the Dominion government's attitude on the settlers' rights issue, it is interesting to show what it has done on the coal lands the title to which now seems doubtful.

A standard-gage railway has been built to the mine site, a distance of a mile. Part of this has been laid through sandstone rock, necessitating heavy cuts at places. At the end of the spur the necessary grading for the different tracks at the mine yard is completed and some of the tracks have been laid. A temporary tipple has been constructed at the mine yard, a little to one side of where the main tipple will be erected, and all preparations are complete for the shipment of coal at any moment. Some 700 tons is lying at the mine mouth for shipment.



Fifty acres of land have been cleared and graded for mine buildings and dwellings to accommodate employees. Nineteen substantial dwelling houses are under construction and almost completed, and foundations are in for a large number of permanent mine buildings including office, messhouse, store, lamphouse, etc.

A good substantial saw-mill has been erected capable of turning out 12,000 ft. per day. A large brick smokestack and foundations for two 250-hp. boilers have been completed and two Stirling water-tube boilers are on the ground ready for installation. Three slopes are in course of being driven. The slope for the manway is now down a distance of 196 ft., and at the face the coal is 11 ft. in thickness and of good quality.

At a point 175 ft. down a level has been driven to the right at right angles to the line of the slope, and places are being driven back from the level to connect with the other two slopes which are being driven from the surface. This level has been driven in a seam which averages 11 ft. in thickness, so that it may be said that all three slopes have 11 ft. of coal at the faces.

Three hundred thousand dollars have been spent to date on this development, and the mine will be ready to ship 300 tons a day within two months and by the end of the year should be producing 700 to 800 tons daily. When the investment at the mines is added to that at Anyox, the company's smelter center, where by-product coke ovens are being installed, it will total in the neighborhood of $1,000,000.

In most of the common types of mechanical stokers the distillation of volatile matter occurs in the presence of oxygen, whereas in hand-fired furnaces the distillation takes place in almost entire absence of oxygen, all of the latter being consumed as it passes through the fuel bed. Even if there should be some tendency to decomposition with the mechanical stokers, the presence of large percentages of oxygen at the point of distillation makes it possible for the hydrocarbons to react with oxygen before the deposition of carbon can really take place.—*Bureau of Mines Bulletin No. 135.*

Weekly Production Statistics

Production figures for the week ended July 20 are as follows: Bituminous, 12,956,000 tons; anthracite shipments, 40,664 cars; beehive coke, 668,000 tons; byproduct coke, 567,500 tons.

While bituminous coal production fell 2.4 per cent. below that of the record accomplishment of the week ended July 13, it came as no surprise. It was known in advance that it would be improbable that so heavy a production could be duplicated during the succeeding week. The production, however, looks especially good when compared with the 11,230,000 tons for the corresponding week of last year.

Anthracite forwardings slumped 4.3 per cent. and with the exception of the week which included July 4 went lower than at any time for many weeks.

While beehive coke production decreased slightly during the week ended July 20 the rate of production in the Pennsylvania districts remained practically the same with labor shortage forming the only retarding factor of importance. The car situation has a negligible bearing on production at this time.

Byproduct coke production continues to climb slowly into new high records. The byproduct ovens of the country were operated at 91.2 per cent. of full time capacity during the week ended July 20. If plant repair could be obviated, this industry could be operated at the present time at 95 or 96 per cent. of full time capacity.

Bunker Coal

Further steps were taken last week by the Fuel Administration to improve the quality of coal for the use of ships in the Atlantic and the Gulf trades. The Tug River field of West Virginia has been designated as a field separate from the Pocahontas field. All coal originating in the Pocahontas, New River and Tug River fields, which may be classified by the Tidewater Coal Exchange for consignment to pool No. 1 or pool No. 2 at Hampton Roads, will be admitted as permissible bunker fuel. Coal in pool No. 44 at Hampton Roads also has been specified as permissible for bunker use. At New York, Philadelphia and Baltimore, coal from mines on the Navy's list, which classifies for pool No. 1, when not mixed with coal from any other pool, is to be used for overseas trade. Coal for that purpose also will be drawn from mines on the Pennsylvania, the Baltimore and Ohio, the Western Maryland and their connecting lines which take pool No. 9, when not mixed with coal from any other pool. Coal from the New York Central and connecting lines classified for pool No. 4 or pool No. 10, as well as coal from the Pennsylvania, the Baltimore and Ohio, for consignment to pool No. 10 as well as pool No. 1 and pool No. 9, is admitted for coastwise trade.

No slack or sizes smaller than mine run may be accepted for bunkering purposes except by special permission by the Fuel Administration.

Bituminous Supplants Anthracite

More than 200,000 tons of anthracite have been stricken from Army requirements for posts, camps and cantonments, as a result of the activities of the fuel and forage division of the Quartermaster Corps. The anthracite has been substituted by bituminous coal and coke, which is available much nearer by. As a result, a saving of 33,000,000 ton-miles has been effected. The Army appropriation has been saved $300,000 in the cost of the coal and $200,000 in the cost of its transportation, to say nothing of the advantages which have come by releasing so large a tonnage for domestic consumption and by saving railroad transportation for other purposes.

Pushing Production

James B. Neale, director of production for the United States Fuel Administration, is encouraged greatly by the success which is attending his campaign for greater production. The work is rapidly being reduced to a systematic endeavor.

At each mine a production committee of six is to be appointed. Three representatives of the mine workers and three of the management will comprise this committee. The committee will do all in its power to spur production to its maximum. These production committees act under the immediate direction of a production chief who will be appointed in each fuel administration district.

Mr. Neale is preparing a letter setting forth some of the more important features of the campaign. He will make it clear that there are plenty of workers to send the coal production to unprecedented amounts, despite the draft, if each miner will work eight hours a day and six days a week. He will also point out that there are many ways in which the operators must do their part.

Mr. Neale points to the achievement of southwestern Virginia as an indication as to what can be done. That district during the week ended July 13 operated at 94 per cent. of its full time capacity. During that week it produced 193,626 tons, which was the greatest weekly

production in the history of the field. Increased labor efficiency was largely responsible for the showing which was made.

Another example of a practical outgrowth of the campaign is the return at the mines of the Mercer Iron and Coal Co. at Stoneboro, Penn., of 150 miners, who had retired from active work as a result of having passed the age limit. These men again are actively mining coal and are enthusiastic over the fact that they are having an opportunity to contribute directly to the winning of the war.

Ralph D. Paine, a writer of national reputation, has been drafted by Mr. Neale to assist in the production campaign.

Smokeless Price Adjustments

Brokers' commissions continue to be one of the most active matters under study at the Fuel Administration. This was the subject of conference last week between Fuel Administration officials and smokeless operators from West Virginia. Price adjustments in the Pocahontas, New River and Tug River fields also were discussed. At present there are nine prices applying on the coals originating in the smokeless area. When the different grades and different allowances and the commissions are considered, there are 48 different prices on the existing schedule. A means of simplifying this schedule is under consideration, but it is probable that no new plan will be announced until the smokeless operators have been given an opportunity to complete new cost sheets which are being compiled.

Brief Washington Notes

Prices covering anthracite mined in Virginia have been announced as follows: Egg, $5.40; stove, $5.75; nut, $5.75; pea, $4.60; buckwheat, $1.55; culm, 90c.; briquettes, $5.30. The prices are subject to a general reduction of 30c. until Sept. 1.

Coke from beehive or byproduct ovens screened and cleaned for domestic purposes, in mixed sizes, is to take a price $1 less than that fixed for selected foundry coke. This schedule was made necessary by the recent rise of the practice of screening and cleaning breeze piles.

While Lake shipments are far from being in as bad shape as they were last year, it has been found necessary to take special steps to expedite the movement of coal for the Northwest. All district representatives interested have been instructed to give preference to Lake shipments. Of course railroad fuel and coal for byproduct and gas uses move ahead of the fuel destined to the Northwest.

In the hope that the delay may be reduced in securing priority orders for coal mine supplies, Roy A. Rainey, of New York, and David D. Bush, of Chicago, have been placed in charge of a bureau which will look after this matter carefully. The work will be done in conjunction with the priorities section of the War Industries Board.

While the section of the Federal Trade Commission charged with determining the cost of coal production has been transferred by executive order to the Fuel Administration, this in no way interferes with the power of the Federal Trade Commission to make investigations and inquiries along the same line. As a result, the Commission now is launching a new inquiry into the cost of coal production to ascertain if profiteering or irregular trade practices exist.

Five cents per ton may be added to the price of run-of-mine, ten cents to prepared sizes and fifty cents to slack if the coal is thoroughly clean. To get the increase, a special permit must be secured from the Fuel Administrator.

Peat Industry Breaks Record

The peat industry in the United States was prosperous in 1917, for the quantity of peat sold exceeded that sold in any preceding year. According to statistics compiled by C. C. Osbon, of the United States Geological Survey, Department of the Interior, the peat sold in 1917 amounted to 97,363 short tons, a quantity greater by 44,857 tons, or about 85 per cent., than that sold in 1916, and by 42,220 tons, or nearly 77 per cent., than the record annual sales, 55,143 tons, established in 1911.

The average price received for peat in 1917 at the point of consumption was a little more than $7.29 a ton, and the gross market value of the output was $709,900, a gain over 1916 of 26c. in average price per ton, and of $340,796, or about 92 per cent., in market value.

The following table shows by years the output and value of peat marketed from bogs in the United States each year since 1908:

PEAT SOLD IN THE UNITED STATES, 1908–1917

Year	Quantity (Short Tons)	Value
1908	*24,800	*$136,610
1909	29,167	127,042
1910	37,024	140,209
1911	55,143	272,114
1912	47,380	228,572
1913	33,260	197,200
1914	47,093	309,692
1915	42,284	288,537
1916	52,506	369,104
1917	97,363	709,900

* Estimated.

The total number of plants producing peat in the United States in 1917 was 18, an increase of five over 1916. All the producers operating in 1916 except two contributed to the output in 1917, and seven companies that were not represented in that year reported commercial production. Many new companies were organized in 1917 that did not complete their plants in time to contribute to the year's output. The plants known to be at work in 1917 were distributed as follows: California, 2; Florida, 2; Illinois, 2; Indiana, 1; Massachusetts, 1; New Jersey, 5; New York, 3; Pennsylvania, 1; and Virginia, 1.

All the producers reported that the demand for peat exceeded the supply, and some stated that, on account of railroad embargoes and the scarcity of labor, they were unable to meet the demands of their regular customers. Improvements designed to increase production in 1918 were made to substantially all the peat plants operated in 1917.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Dr. Garfield was much heartened by the wonderful response of the mine workers to the appeals of the Fuel Administration for steadier work and larger output. He said that the passing of the 13,000,000 ton mark on the week ending July 13 would warrant the giving of a service stripe to everyone of those taking part in the production of that tonnage. The output in the corresponding week of the year before was 1,479,000 lower. Unfortunately the output of the week ending July 20 was 300,000 tons less than in the week before, though car shortage was only 3.9 and labor shortage 4.2 per cent.

The Fuel Administrator has created a Bureau of Labor which will be charged with the settlement of controversies between coal miners and operators for the period of the war. This is not a radical departure, but it marks the final decision to let mine-labor problems be settled by a Fuel Administration board and not by the War Policies Board of the Department of Labor.

LABOR DISPUTES TO BE SETTLED BY COAL MEN

John P. White, the former president of the United Mine Workers of America, and Rembrandt Peale, a coal operator of central Pennsylvania, are named joint heads of the bureau. Probably no duties different from those they have been recently performing on behalf of the Fuel Administration will be given them. The announcement of the decision to establish the bureau is dated July 23.

Michael Washko's death in the Beaver Meadow Colliery made it necessary for the Lehigh Valley Coal Co. to announce its intention to stand by the *extra vires* declaration of the Anthracite Conciliation Board. That company promptly announced its intention to pay the $150 to the family of the deceased and to comply with the other terms of the dictum relative to the funerals of men killed in the mines. The Brookside colliery of the Philadelphia & Reading Coal and Iron Co. also had a death, but for the first time for many years work continued as usual.

It has always been a cardinal feature of the United Mine Workers of America to keep such persons as are engaged in the selling of intoxicating liquors from membership in the union. When the latest button drive was made in district No. 9 a half dozen saloon keepers who work in the mines were, in accordance with Article 14, Section 2, page 3b, refused buttons on making application for them. The Liquor Dealers' Association has made a complaint, but the by-laws are fixed. The saloon keepers will have to leave the union, and without union membership they cannot work in the mines. The companies in District No. 9 are unofficially urging their men to continue "buttoned up."

MEN AT GREENWOOD COLLIERY RETURN TO WORK

On Saturday, July 20, the Greenwood Colliery mine workers returned to work, agreeing to leave their grievances to the action of the officers of District No. 1. If these officials cannot get a settlement, then the matter will be brought before the Conciliation Board. The Greenwood miners are said to be getting $3.83 per day, whereas other company miners are getting $4.25. If this is a fact an evening up is desirable even though it is clear that the contract does not call for it. No concern can get and keep desirable men if it pays less than the current wage. Mines with less than the usual scale gather, as a rule, all the undesirable men in the community and keep them discontented. The best men are none too good for successful operation, and every concern should seek to have men of at least average quality.

Petty strikes recently occurred at the mines of the Lehigh Coal and Navigation Co., which operates in the Panther Creek Valley, but they have been settled. A strike at the No. 4 colliery of the Lehigh and Wilkes-Barre Coal Co. was soon ended, work being resumed on July 22. Apparently it was a button strike. The men who refused to pay their union dues were aliens, and they were accused of pro-Germanism. They have now left the district.

The men of the Carleton Coal Co. near Dunmore, Penn., a suburb of Scranton, went on strike Friday, July 19, to protest against an increase in the price of house coal. On Saturday the men were confronted with a bulletin reading, "This colliery will be idle until further notice." This notice was soon removed and another replaced it naming Monday as the day of resumption. The men returned to work Monday but they purposed to meet again to discuss the matter Thursday. They threatened that if at that time they were not, or had not been informed of a restoration of the former price they would go on strike again. About 90 men were involved.

The employees of the Lehigh Valley Coal Co. have been talking of striking in the event that the company does not speedily supply their bins with coal. The Lehigh company decided July 25 to give the mine workers the preference in deliveries and to stop all local sales of fuel except those to its own men. The company and local haulers are now busy filling the mine workers' orders.

The Hazleton draft board has decided that it would not regard stenographers and clerks in the purchasing departments of coal companies as essential employees or give them deferred classification in the draft. Howard Zullick, who was engaged by Pardee Brothers & Company in this capacity was the man refused such classification. Edward V. Summers was also refused deferred classification by the Ironton (Ohio) board, which so notified the Hazleton authorities. It had been represented that he was an essential employee of the Cranberry Creek Coal Co., Hazleton, Pennsylvania.

NOT ABLE TO FIGHT, VETERANS GO BACK TO MINES

In central Pennsylvania efforts still continue to induce every man to sign a pledge card to do his best during the continuance of the war. A new source of labor has been unearthed near Stoneboro, Mercer County, Pennsylvania. Stoneboro lies on the edge of the coal field. It is one of the time-honored fields of the state like the Huntingdon and Broad Top region and the Tioga County field. It has a lot of hard-headed Scotch and English miners, who made money by patient, steady work and bought homes. When they reached competency and declining years they left the mines, the coal being high grade, but thin, and somewhat hard to mine.

The call "More coal, more coal" has brought these miners back to the mines to the number of about 150. They have mined so far about 4000 tons and expect to mine 500,000 tons a year. So far the coal is being stacked waiting for railroad communications. The mine will be worked by the Mercer Iron and Coal Co. The spirit of these veterans of the pick is admirable and their example should be followed throughout the mining regions.

At the Pipe Creek mine of the A. J. Morgan Coal Co., in the Belmont field of Ohio the mine workers were idle for two days fearing that pro-Germans would blow up or otherwise injure the mine and its occupants. Twice the mine workers saw strangers lurking near the mine before the whistle blew. Vice President Ledvinka of the United Mine Workers of America with a committee of the employees searched the mine thoroughly but found no evidence of an intruder, so the men returned to work.

In Tennessee, W. E. Myer, the state fuel administrator,

has been much troubled by the threat of a strike at the mines of the Battle Creek Coal and Coke Co., Orme, Tenn. The mine lies near the southwestern end of the Tennessee coal field in Marion County not far from Chattanooga, and where the narrow lens of coal is about to enter Alabama. The men claim they are not getting as much as mine workers in other places. Rembrandt Peale is to act as arbitrator. About 150 men are employed at the Orme mines. As soon, however, as the fuel administrator had made his plea and proposition they decided to keep at work.

In Kansas, 50 foreigners are endeavoring to stop operations in the important Cherokee field, according to word received by Governor Capper from Sheriff Bob Frazier.

Hecla Company Gives Service Medal

By W. L. Affelder

General Manager Hecla Coal and Coke Co., Oliver Building, Pittsburgh, Penn.

The man who stayed at home and did not do his utmost toward helping his comrade who had gone to war will have many unpleasant questions to answer when the war is won and the maimed and crippled soldiers return; but the stay-at-home who did his utmost to supply the necessary sinews of war need have no misgivings.

In order to promote a feeling of pride for duty well and faithfully done among the two thousand employees of the Hecla Coal & Coke Co., of Pittsburgh, Penn., I have devised an Honor Medal for Industrial Soldiers, which is illustrated herewith. A notice printed in five languages—English, Italian, Slovak, Hungarian and Italian—was distributed among the men, and it fully explains the way in which the medals and bars are to be used. The alternation in colors of the bars—silver-plated and bronze—is not really essential, but it enables a person to see at a glance whether or not a man's string of bars is uniformly continuous; whereas, if all bars were of the same color, the omission of a month would not be so readily noticeable. The notice and medal are reproduced below:

"Beginning with the month of July, we will give to each outside or inside employee a medal like the one shown in the illustration, with a bar bearing the date of the month in which he first works every day. For each month that he works every day a bar, engraved with the proper date, will be added. When your buddies come back from the war, you will be able to show them by your badge and monthly bars that you have helped to win the war by working every day. The war cannot be won without coal and coke. You can be of just as great service toward winning the war by working every day as an "Industrial Soldier" at our mines and coke plants as by fighting in Europe.

"Remember that the soldiers do not lay off on account of drinking and holidays. Show them by your badge that you were as good a soldier as they were. If you do not win a medal in July, be sure to get one in August. Then be sure to get a new bar each month." The design of the medal has been patented, but both the medals and easily attached bars can be obtained from the Mine Safety Appliances Co., of Pittsburgh, Penn.

We Will Settle Our Own Disputes

At a recent conference held in the city of Washington, D. C., between the United States Fuel Administrator, Harry A. Garfield, and the international officials of the United Mine Workers of America, a complete understanding was reached whereby all questions pertaining to labor in the coal-mining industry will remain under the jurisidiction of the United States Fuel Administrator. This is in accordance with an understanding previously reached between the Secretary of Labor and the Fuel Administrator.

In order that this arrangement may be made effective, the United States Fuel Administrator has created a Bureau of Labor, to which all matters relating to labor controversies will be referred for settlement. He has appointed John P. White, former president of the United Mine Workers of America, and Rembrandt Peale, a coal operator of Central Pennsylvania, joint heads of this bureau, with power as his deputies to consider and dispose of all labor matters relating to the coal-mining industry which would come in the ordinary course of business before the Fuel Administration, the decisions to be made being subject to the procedure prescribed in existing joint agreements.

The following statement of principles was made by H. A. Garfield, United States Fuel Administrator, at conferences at which were present Frank J. Hayes, president, John L. Lewis, vice president, William Green, secretary and treasurer of the United Mine Workers of America, and also John P. White and Rembrandt Peale of the Fuel Administration, all of whom acquiesced in the statement as expressing their understanding of the principles followed by the United States Fuel Administration and by the United Mine Workers in settling questions relating to labor in the coal-mining industry, it being understood that wherever the Federal Government is called upon to intervene or of its own motion intervenes in the settlement of such questions, whether in organized or unorganized fields, jurisdiction shall remain for the present and until otherwise arranged in the hands of the Fuel Administrator.

"The United States Fuel Administrator understands

(a) That no strike shall take place pending the settlement of any controversy until the dispute has been reviewed and decided by him.

(b) That recognition of the unions shall not be exacted during the continuance of the war except where now recognized by collective bargaining.

(c) That where, by joint contract between employer and employed, machinery is provided for the settlement of controversies, the United States Fuel Administrator shall not be required to intervene or to mediate until such means have been invoked and the remedy exhausted without reaching adjustment.

(d)) That where the United States Fuel Administrator intervenes, substantially, the principles, provisions and practices laid down in the Maryland and Upper Potomac Settlement of May 6, 1918, shall be accepted by the workers and employers and their chosen representatives as sufficient.

(e) On the basis of the foregoing understanding, which he regards as just and imperative in the present crisis, the United States Fuel Administrator has insisted and will continue to insist that any adjustment of labor questions in the coal-mining industry, whether by joint agreement between operators and mine workers or by agreements severally made with the United States Fuel Administrator, shall embody wherever applicable, and substantially, the principles, provisions and practices laid down in the Maryland and Upper Potomac Settlement of May 6, 1918, and recognizes the authority of the International Union of Mine Workers (sic) in the organized fields and their jurisdiction over controversies arising in said fields. More specifically, the United States Fuel Administrator has insisted and will continue to insist on all such settlements.

(a) That employers will be required to relinquish the right to discharge employees because of affiliation with labor unions.

(b) That employers will be required to recognize the right of their employees to organize by peaceful methods that do not interrupt production.

(c) That the so-called automatic penalty clause now in force, being regarded by mine workers as a cardinal principle of collective bargaining during the continuance of the war, will be included in all agreements as a condition precedent to the allowance of increased price permitted to operators.

(d) That where the union shop now exists, the same shall continue, and where union and nonunion men work together, the continuance of such condition shall not be deemed a grievance."

Exemption of West Virginia Miners

The production of high-grade coal such as West Virginia produces has caused the Provost Marshal-General to take action to prevent a depletion in the ranks of the mine workers. Local draft boards of the state have been given authority under the selective service regulations to exempt miners, and according to an announcement from the office of the Provost Marshal-General diggers of coal can now be placed in a deferred class.

The draft has demoralized the coal industry of the whole state, but especially of the southern half. Coal operators have hesitated to interest themselves in seeking the exemption of mine workers both for the broadest patriotic reasons as well from a desire to avoid even the appearance of interfering with the free action of their mine workers. They felt, however, that it was most important to get out coal and that it could not be mined and loaded without men.

It is now decided that in the future men employed in and about the coal mines of West Virginia will not be accepted for service in the army.

Major Stuart, of Huntington, in charge of recruiting for the army in West Virginia, received instructions from the War Department July 23 to discontinue all recruiting activities in the coal-mining regions and to scrutinize closely enlistment applications filed by mine workers. The following is a copy of the telegram Major Stuart received:

"It is reported essential coal workers being enlisted. Direct all your parties cease activities at once in or about coal-producing centers. Exercise greatest care in accepting any applicants who have been in any way connected with output of coal. Each case of a man who claims to have severed connections with such occupation with a coal company with no intention of resuming connections with such occupation must be carefully investigated by communication with former employer, and if it appears that the applicant has recently left such employ without the consent of the employer he should be rejected. The coal industry must not be interfered with through enlistment."

Reports received here from the coal-mining centers are to the effect that a number of miners are not working regularly and Major Stuart is making an investigation.

Operators and Men To Work Together*

By JAMES B. NEALE

Director of Production of the United States Fuel Administration

During the past month I have had interviews with and have received letters from many coal operators and labor leaders, and, as a result, I am firmly convinced that sufficient coal can be produced by the men, the development and the equipment now available, provided every man and boy from the highest official to the smallest trapper will put forth his very best effort. The operators and their staffs alone cannot do it; nor can the mine worker alone achieve it. It can only be done by the coöperation of both parties in interest, working hand in hand with grim determination to rid the country of the coal shortage, which may be confidently regarded as the greatest menace we face in the winning of the war.

The operators must work as they have never worked before. They must be in and about their mines, thus showing in a way which can be seen their deep interest in the Government's determination for increased tonnage. They must take up with their superintendents and mine bosses questions of efficiency and working conditions so that the best opportunities may be afforded to the workers. I am confident that much benefit will come if the operators themselves and their superintendents will keep inquiring of the mine bosses in regard to what can be done in order that the mine workers may produce more coal. The operator must take away from the mine workers every excuse for days absent or short-hours worked. The miners cannot work if pit cars are not furnished, if the miners are gassed out, if the colliery is wanting timber, etc. These small details must now assume large proportions and must be looked after with the greatest care.

The mine worker must report for work each day and must actually work his full eight hours and produce more coal than ever before. The mine worker is much more likely to do this if he sees that the mine management is making almost superhuman effort to enable him to work day after day under the best possible conditions. There is no doubt that in very many cases the miner has lost many days and has frequently worked short hours. This has caused a great loss of production. But, at the same time, there is also no doubt but what a large tonnage has been lost by the carelessness and inefficiency of the mine management.

This country is facing an exceedingly serious crisis. Increased coal production is absolutely necessary to success. The winning of the war then lies with coal operators and coal miners. There are two powerful controlling elements and one cannot work separate and distinct from the other. One element is the man power and the other is the owners, managers and superintendents. I am sure it will be an inspiration to the mine workers to see the operators with their coats off. The men about the mines should know the big boss. The director of a coal mine who does not direct is a menace to the country at this time. No matter how earnest a pit boss may be the edge is taken off his service when he sees that those above him are not interested.

The coal operator must not pass the buck to the men. Don't lay the blame altogether on the mine workers. Don't think things are just right and let it go at that—look into your operating conditions. Lots of days have been lost by mine workers for which they were not responsible. Results we must have and in such a crisis nothing is too petty to receive the personal attention of the mine owner.

*Abstract of address to Fairmont Country Club, but summarizing also some remarks made to a representative of "Coal Age."

PRAISED FOR THEIR EFFORTS, FAIRMONT OPERATORS ARE TOLD TO HELP THEIR MINERS PRODUCE COAL

EDITORIALS

Size of Shaft Pillars in Mines

A GLANCE at the many empirical rules now being used for the determination of the size of shaft pillars is enough to convince anyone that no considerable progress has been made in the science of roof breakage and subsidence. All we have learned is that somehow, when coal is extracted, the roof over the undisturbed mineral suffers with the roof over the disturbed mineral. That is something, of course. In fact it is much, because it lays entirely aside the assumptions that the roof breaks between the pillars or arches between them, or again chokes up tight because loosely piled fragments occupy a larger volume than unbroken measures. When we realize that the strata surrounding the shaft are mysteriously pulled apart by the destruction taking place around them, we part with all belief that the principle of shear explains roof failure.

Something, therefore, has been learned even if the formulas based on depth and coal thickness are not just exactly reliable; even though one authority insists on a pillar with about 100 times as many square feet as seems necessary to another; and even though Merivale would have the pillar for an 1800-ft. shaft only 165 ft. square, whereas Hughes demands one 1800 ft. in diameter.

Imagine the roof of the mine as a plate of iron. When it bends over the shaft pillar the point of maximum tensile stress will be over the heart of the shaft pillar, which is usually the location of the shaft. This will be the case unless the stiffness of the roof is insufficient to enable the iron to bend in a common arch over the shaft pillar. When the roof is weak, or the pillar large, the iron may sag in the center and form two folds over the pillar. Let us term the single arch an "anticline" and the dip into the excavated area a "syncline." The anticline may be as broad as the synclines on either side, provided the shaft pillar is wide enough to accommodate it. But if the pillar is too broad, there will be a sag on the top of the shaft pillar. The maximum breadth of the syncline is, of course, determined by the strength of the roof; in other words, its breadth depends on the number of feet that will stand unsupported. The size of the anticline is similarly determined, unless the pillar is smaller than the syncline. A shaft pillar just as wide, or less wide, than the breaking span of the syncline will tend to fracture on the top of the anticline or at the shaft location. Thus, if you want to protect the shaft, make its diameter larger than the breaking span. This span depends on the depth of the roof and not on the coal thickness.

Perhaps the size of the pillar should not be schemed so as to prevent surface breakage of the pillar at the shaft. That may be too rigid a requirement. We may content ourselves with requiring merely that the action at the shaft shall not be made too severe by the breaking of the roof over too narrow a pillar, for a small pillar will break the roof more severely than a large one. In the event that we are not solicitous about all breaks at the shaft, but only that the breaks shall be followed by only moderate movement, then we are justified in considering coal thickness; for the movement on breakage where the coal is thick is more considerable and the general distortion of the measures greater. The horizontal shears, for instance, are more marked where the roof is subjected to a greater depth of collapse. The tilting of the measures is also greater, for with a given length of tilting strata a greater tilt has to be afforded. As the span of an unbroken roof varies with numerous indeterminable strength factors in the roof material, it is hard to say offhand how big a shaft pillar should be. The experience of mines in the neighborhood is the best criterion, especially if the manner of working is uniform.

The thickness of the coal has little to do with the problem if you intend to support the roof over the whole area mined, as in Illinois; or if, as said before, you intend to make the shaft pillar so big that the breakage cannot reach the shaft or adjacent buildings.

Reclaim the Sulphur

"THE peaceful ages of history have seldom been the productive ones." War causes many rude awakenings. A few months ago most people considered this country almost, if not entirely, self-supporting. Of course, it was recognized that certain articles of commerce and consumption—such as tea, coffee and rubber—necesssarily could not, on account of climatic conditions, be produced in continental United States. But of minerals we believed that we possessed an abundance of all except the more rare ones, such, for instance, as vanadium and molybdenum. Few, if any, of the ordinary run of people ever dreamed that even under the stress of war we would face a shortage of such a common substance as sulphur.

However, a shortage in sulphur has developed, and it has already assummed such proportions that the Government has commandeered the supply, both as to stocks and mines. The existing sulphur mines of Louisiana and Texas are being worked to capacity, and the stocks accumulated in past years are being drawn upon heavily. It is essential, therefore, that additional sources of sulphur be found, and found quickly.

At present sulphur is secured from the reduction of pyrite ores and from smelter gases, but the amount thus available is not sufficient to meet the present demand. Probably at least half a dozen "peace" industries, as well as the vast explosives program necessitated by our participation in the world war, demand the use of sulphur. Thus the rubber industry, the manufacture of news print paper, fertilizer, and the manufacture of storage batteries require the use of sulphur either raw or

in the form of acid. Black gun or blasting powder contains ground sulphur as one of its three ingredients, while smokeless powder almost universally used as a propulsive for military projectiles requires sulphuric acid for its manufacture. The same is true of gun-cotton, piric acid, dynamite, nitroglycerin, lydite, cordite, trinitrotoluol and tetranitrophthalein.

Sulphur is in nature fairly widely distributed. It occurs free in certain localities, the largest and best known of such deposits probably being that in Sicily. It also occurs combined with iron and copper in the form of pyrite. This mineral is found in many regions and is probably the most widely distributed of any of the natural sulphur compounds. The "sulpur diamond," with which people in the anthracite region are familiar is a crystalline form of pyrites, while the "brasses," well known to miners of bituminous coal, are formed of the same material.

Brasses, as is well known, are a detriment to any coal. The presence of sulphur in coal always tends to produce clinker on combustion. In metallurgical processes sulphur in the fuel is liable to unite with the metal being treated, rendering it impure and not suited to certain purposes. Thus high-sulphur coke produces a hard, brittle iron much inferior to the purer product made with low-sulphur coke or charcoal. Furthermore, brasses or a high sulphur content in coal exert a potent although possibly an imperfectly understood influence upon the spontaneous heating and possible ignition of the coal when stocked.

In certain localities and in certain coal beds brasses are much more numerous than in others. In some beds in Novia Scotia, in West Virginia and in Illinois pyrite in one form or another is found in such quantity as to be ordinarily considered a nuisance. If, as is often the case, this mineral is found mixed with coal from which it cannot readily be separated, the mixture will not stand shipment for any great distance on account of its liability (almost certainty) of firing upon exposure to the air.

A means or rather process has been devised whereby sulphur may be extracted from coal brasses. The equipment necessary is comparatively simple and inexpensive, and it would appear that the erection of a plant for the recovery of sulphur would be commercially justified wherever pyrite in sufficient quantity may be secured from a mine or group of mines.

The treatment to which the pyrite is subjected, known as the thiogen process of sulphur reclamation, is comparatively simple. The pyrite is roasted or burned, forming sulphur dioxide gas. This is then mixed with a certain proportion of fuel gas (either natural or producer gas) in a reaction chamber containing a catalytic mass. The sulphur in the gas is thus liberated and condenses or sublimes in an extension or cooling chamber. By this means practically pure sulphur is secured from a waste mine product. Under reasonably favorable conditions it is estimated that the cost of producing sulphur by this process should not exceed $7 per ton, about 2½ tons of pyrite being consumed per ton of sulphur produced.

It has been estimated that in the coal fields of the United States it would be possible within a few months (necessary for construction) to produce by this process 1000 tons of sulphur per day. While this would not be sufficient to anywhere near meet current demands, it would help greatly in that direction. Furthermore, the reclamation of a valuable product from what has heretofore been considered a nuisance, a necessary evil, and a waste, is a step in the right direction. This is true conservation.

Railroads Make Raid on Production

THE PUBLIC is disposed to make snap judgments. Last winter, when it found itself short of coal, it blamed the producer and Dr. Garfield. Then slowly it veered round to the idea that the railroads were to blame, and so it condemned the railroads and Dr. Garfield. But now the Government has the railroads, and there is a strong disposition to argue that they must therefore be more efficiently run than when in private hands; and as evidence accumulates that the production of the mines now but barely exceeds the capacity of the car service, the public is beginning to chide the operator and Dr. Garfield—always Dr. Garfield, be it noted—for the coal shortage, past, present and prospective. The operators and Dr. Garfield are accused of not being forehanded. The public asserts that their production campaign was not started early enough.

As a matter of fact, they have been forehanded. They started their hue and cry just as soon as it seemed possible that a car supply adequate to justify their campaign might somehow materialize, if only for a few brief weeks. The operators and Dr. Garfield talked production so long, loud and persistently to the miners left them by the draft and by the labor recruiters that they were overheard by the public. The public shook its head, said these lectures showed something was wrong, and if something was wrong why had it not been corrected before?

The public always acts in this illogical manner. No one can convince the dear people that anyone has ever shown any judgment or foresight. When the railroads were day after day laying the mines idle no one could talk production without exasperating the miners. No employer can scold his men for being idle when no work is provided. At some places he cannot scold today with any good grace.

We wager it is not an easy matter to preach a large production in the Hazard field in Kentucky, where in the week ending June 29 production was 36.5 per cent. short of capacity because of car shortage. The week following it was still 20.7 per cent. short. How would the average American take to a lecture on working hard and steadily if he was only allowed to operate his factory four or five days a week? The car shortage in those two weeks was in the Fairmont region of West Virginia 28.4 per cent. and 9.9 per cent. respectively. In northeastern Kentucky it was 19.8 per cent. and 8.5 per cent. In the Westmoreland field it was 16.6 per cent. and 6 per cent.

It is always difficult to make preparations for a prospective psychological condition. Propaganda to be popular and appear practical must have reference to an existent, not to a hypothetical, condition. If for months men have been working short time and have been highly incensed at that fact, it is hard to lecture them on the duty of working steadily without giving offense; and it is extremely hard to swing them into line when con-

DISCUSSION BY READERS

Travel of Electric Current

Letter No. 2—Referring to the inquiry of "Student," *Coal Age*, July 6, p. 35, permit me to suggest that experiments have proved that direct-current electricity permeates the entire body of the conductor, which is not the case with alternating current. In alternating-current practice, there is what is termed a "skin effect" in the conductor. This term is used to describe the condensation of the current on or near the surface of the conductor.

To one who cares to investigate, it will be of interest to see how the character of these two kinds of current has been provided for in the construction of the bus bars of switchboards, for direct and alternating current. In the former instance, when direct current is used the bus bars are made solid, while in the latter they are constructed in the form of tubes.

The higher the frequency of the alternating current, the thinner the walls of the tubes may be made, which shows that a tube having the same outside diameter as a solid rod or wire will carry the same current, under the same pressure, in alternating-current practice

Camp Jackson, Columbia, S. C. W. J. GRAHAM.

Letter No. 3—In the issue of *Coal Age*, July 6, p. 35, "Student" asks whether an electrical current flows over the surface or through a wire conductor.

Little is known of the real nature of electricity, and we must judge of its action by the effects produced. We read of a current flowing in or through a conductor, and, while it is natural for the mind to picture to itself a material quantity of something we call "electricity," one quickly realizes that the idea finds expression in the thought only. Experiment has enabled us, however, to determine the strength of an electric current or the so-called quantity of flow, and to measure the electromotive force and determine approximately the velocity of a current flowing in a conductor.

These measurements, however, throw no particular light on the mode of transmission, except as pointed out in the editorial reply to this question, where it is shown that the allowable current capacity of a conductor, as determined by the heating of the wire, bears such a relation to the diameter of the wire as to suggest that the entire mass of the wire is affected.

STATIC CHARGES DIFFER FROM VOLTAIC ELECTRICITY

It would seem that the idea of a current flowing over the surface of a conductor, rather than through the body of the wire, originated from experiments on *charged* bodies. These experiments showed that an electrical charge resides upon the surface of such a body. For example, when a metal cup is placed on an insulating stand and charged with electricity derived from an electrical machine or other source, there is found to be no effect produced if a metal rod or ball is brought in contact with the inner surface of the cup. If, however, the ball or rod is brought into contact with the outer surface of the cup it at once becomes charged.

While this is true of a static charge of electricity, it does not prove that a similar condition exists in respect to a current passing in a conductor. The two forms of electricity known as "static electricity" and "dynamic" or "voltaic electricity" may differ materially from each other, and what is true of a charged body is not necessarily true of a conductor through which a current is flowing. The distinction between *positive* and *negative* electricity, as being divergent elements, does not appear to affect the status of current electricity in the same degree or sense as characterizes a static charge. It may be stated with much truth that what we do not know about electricity far exceeds our knowledge of the subject.

A CURIOUS CONCEPTION OF ELECTRIC FLOW

One modern view, which has not received any general acceptance, however, is the suggestion that an electric current does not flow through a conductor or over its surface, but passes through the ether or other dielectric surrounding the conductor, the idea being that the so-called wire conductor merely forms a sink where the electrical energy dissipates itself and, in this capacity, acts to direct the current.

Such a theory, however, does not appear to lend itself to the observed and established laws of electricity. Practically, the current capacity of a wire conductor is determined by the heating of the wire, which first shows a dull red glow and, as the strength of the current increases, the wire becomes quite hot, the degree of heat often reaching the melting point of the wire. It is safe to say that these characteristics or effects do not support the idea that the current flows over the surface of the conductor only. ELECTRICAL ENGINEER.

Heat Treatment of Axle Steel

Letter No. 1—In connection with the recent letters relating to different phases of mining equipment, allow me to indorse the statements of P. K. Howard, *Coal Age*, Apr. 13, p. 710, by which he calls attention to the importance of the heat treatment of mine-car and locomotive axles.

As Mr. Howard has said, this is a matter that has not been given much thought by the average mine official, who seldom stops to consider, if he really knows what is the kind of axle steel best fitted for mine-car running gears. As a general rule, this kind of material is bought from a price standpoint. No thought is given to the analysis, tensile strength or hardness of the steel. Also few seem to realize the great advantage of using a heat-treated axle. This latter may cost a few cents

a pound more than the ordinary soft steel, but it will pay for itself many times over in a short time.

By heat-treating an axle of, say 0.40 to 0.50 per cent. carbon content, a tensile strength of about 125,000 lb. per square inch is secured with a hardness of about 40 on the scleroscope scale. The same analysis steel, cold-rolled, gives a tensile strength of about 80,000 lb. per square inch. The advantage in using as hard and as tough a steel as possible is self-evident when the extremely hard usage of mine-car service is considered.

By using heat-treated axles, bent and broken axles may be eliminated. This item itself saves considerable blacksmith and car-labor expense. Then, again, when a heat-treated steel is used it is found that wheel hubs are not enlarged to such an extent as when a soft axle is employed. Also, the axles themselves do not wear down as much as is usually the case.

I know of one large anthracite mining operation that has been using heat-treated steel for axles for the last seven or eight years. When this company was using ordinary soft steel it sold from one to two car loads of scrap axles every year, but since using heat-treated axles it has not scrapped one car load. These axles have also shown a decided saving in shop labor.

Another place where a good grade of steel is necessary is in anti-friction running gear. As mine operators become more and more convinced of the advantages of an efficient anti-friction running gear, they also realize the advantages of using a good grade of axle steel.

Kingston, Penn. E. A PEARSON.

Electric Mine Haulage

Letter No. 1—Having had a number of years' practical experience as a motorman and in the construction of almost every type of locomotive used, and being familiar with the various conditions met in mine haulage, and knowing the kinks it is often necessary to adopt to secure the best results, the discussion, in *Coal Age*, regarding the different types of locomotives in use, has greatly interested me. I agree with Steven D. Otis, who suggests, June 15, p. 1124, that "practical mining men should . . . give their experiences." It is true that the present is no time to hoard up knowledge that will advance the common interests of the coal-mining industry.

Mr. Otis gives a very interesting description, in his letter, of the succession of improvements that followed the displacement of mules by mechanical haulage, in a Pennsylvania mine of which he had charge. In the course of his letter, he brings out some interesting points in regard to the practical operation of storage-battery locomotives on main haulage roads, by the use of roller-bearing instead of plain-bearing cars.

Conditions Determine Type of Locomotive

Experience has long since convinced me that the question of replacing mules with gathering locomotives must be governed largely by conditions underground, and that each installation must be studied separately and decided in accordance with these conditions. The flexibility of the storage-battery locomotive and its adaptation for gathering purposes cannot be denied. However, as stated by "Motorman," in an interesting letter, Apr. 27, p. 800, there are conditions under which better results are obtained by the use of the cable-and-reel type of locomotive.

The recent development of the cable-and-reel locomotive and its combination with the crab type presents many advantages over the original design. Scarcely a year ago I installed several locomotives of this type, which have proved very satisfactory. These locomotives were installed both for gathering purposes and main haulage. The claim of greater capacity, reliability and convenience was what led to the installation.

Crab-and-Reel Replaces Storage-Battery Type

No one will claim that any one type of locomotive is suited to all conditions alike. In one instance that I recall, a large coal-mining company replaced the storage-battery locomotives, which they were using on their gathering hauls, by locomotives of the crab-and-reel type. They had used the battery locomotives for a considerable time but found that better results could be obtained, under the conditions existing in their mines, by employing the cable-and-reel machine. The result proved the wisdom of making the change. I might cite other instances to show that the service conditions of different types of locomotives are being closely studied today and improvements in the structural and electrical details are being constantly made. On this account, the characteristics of the different types of machines are growing in importance each day.

Someone has stated that the storage-battery locomotive is easy to operate. It must be remembered, however, that the operation depends almost wholly on the experience and skill of the motorman. As has been pointed out by the writer who signs himself "Storage Battery," June 1, p. 1028, an unskilled motorman or the use of bad rolling stock will quickly drain the batteries and render this type of locomotive inefficient. The same writer closes his letter with the statement that "the success or failure of any gathering haul depends almost entirely on the condition of the track, the kind of mine cars and locomotives and the knowledge and skill of the motorman."

Successful Storage-Battery Installation

The following citation in my own experience may prove of interest in this connection: Not long ago, I installed, in a large mine, a General Electric storage-battery locomotive of the two-motor, 5-ton type, equipped with 80 Edison storage batteries. The charging equipment consisted of a 10-kw. motor-generator set and switchboard.

Alternating current is supplied, at this mine, from a high-tension system, of 2200 volts, primary, and 220 volts secondary, the latter being used for operating the alternating-current, coal-cutting machines. The motor-generator set was used to convert the 220 volts of alternating current into 250 volts of direct current, which was used for charging the locomotives, this current being regulated by the rheostat on the charging panel to the proper charging voltage. The charging current of this equipment is 60 amp., at 110 volts. The arrangement is such that the battery is automatically cut out when fully charged. In my opinion, where alternating current is available, this equipment is the most nearly ideal system of gathering or main haulage.

The storage-battery locomotive was used on the main haulage road, for hauling the coal to the slope bottom. On July 3, I hauled 413 tons of coal in eight hours with this locomotive, which could have hauled 500 tons of coal, in that time, had the coal been available. During the noon hour, from 12 to 1, the batteries were boosted. In this mine, the grade on the main haulage road is in favor of the loads, but the mine cars are equipped with plain bearings.

T. O. HUGHES,
Windber, Penn. Mining Electrician.

Safety in Shotfiring in Mines

Letter No. 6—It would seem that the subject of securing the greatest safety in the firing of shots in mines has been discussed from almost every angle; and, yet, it appears to me that sufficient emphasis has not been placed on the more general use of permissible explosives.

It is but a few years ago that the matter of testing explosives used in coal mines was taken up by the Federal Government. At a great outlay of labor and expense, the Government has since conducted tests on the different explosives submitted to them by manufacturers as designed for coal-mining use.

Besides making careful tests of these explosives and preparing a list of those powders that passed the test and were therefore considered safe to be used in the mining of coal, the engineers of the Government went further in their investigations of the characteristics of different explosives and the elements involved in the blasting of coal that tended to make the work dangerous. These investigations enabled the engineers to recommend safe practices both in the manufacture and the use of explosives.

BLACK BLASTING POWDER VS. "PERMISSIBLES"

When one considers the universal use of black powder for the blasting of coal in mines and the large number of accidents that have resulted from that cause, the work undertaken by the Government appears almost revolutionary in its character and extent. The movement, however, met with great opposition from large numbers of miners and the adoption of the so-called permissible powders, in many mining districts, has been slow indeed. It required much exploitation to educate the miners to the proper use of this new class of explosives, and to convince them of the greater safety secured by their use.

While the movement has proved successful in the more important coal-mining states and districts, there are still many mines and miners throughout the country that continue to use black powder for the blasting of coal. Recently, a couple of our old miners who had been absent for some time returned and asked for work. They stated that they liked the work and were given good places where they had been. They said their only reason for returning was the fact that the miners in those mines were using black powder. These men had come to know the greater safety of permissible powders and could not be induced to remain where black powder was used in the mine.

The habit of using permissible powders is a good one, and there is no reason why there should any longer be any hesitancy of miners in adopting these powders. It is my opinion that the Government should now take active steps to make their use more general, as it is one of the important features of coal mining, in respect to safety and economy. It is my belief that there is not a seam of coal that cannot be effectively blasted with permissible explosives. I have witnessed the best results obtained where it had been contended that permissibles would prove an absolute failure.

Where permissible powders have been tried, and failed, the result is commonly due to a misuse of the powder, either in the weight of charge employed or in the grade of powder used. The mistake is frequently made, also, of failing to properly tamp the hole. Permissible powders should be thoroughly tamped to the mouth of the hole, and the same care must be exercised in their use as in blasting with black powder. The idea seems to prevail among many miners that, because permissible powders are quicker and stronger than black powder, they do not require the same tamping, but this is a mistake. All holes should be well tamped to secure the best results and insure success.

W. H. NOONE.
Thomas, W. Va.

The Mining Situation

Letter No. 6—I have been greatly interested in the discussion of the present situation in the coal-mining industry, and particularly in the letter of my friend, R. W. Lightburn, *Coal Age*, July 13, p. 78. I do not feel, however, that all the blame should be placed on the miners. Neither are the operators wholly to blame.

A great responsibility rests, at the present time, on the mine foreman, whose duty it is exert himself more than anyone else in the mine to keep things moving. An instance that came under my observation but recently leads me to think that in a number of cases where the mine's output is delayed the blame rests on the foreman in charge.

While there are many good, loyal foremen who are doing all in their power to increase the output of their mines, it must be admitted that there are foremen who are only too willing to lay down on the job. They realize that they cannot be held accountable for the mine not running when they are able to offer the excuse that "only half of my men showed up this morning, and we were forced to shut down." The instance to which I refer as illustrating this disposition on the part of some foremen to neglect their duties is the following:

WHERE THE MINE FOREMAN WAS TO BLAME

A few mornings ago, the miners who worked in one section of the mine where the roof was bad and the roads none too well timbered found, on reaching their places, that a heavy fall of roof had occurred during the night, blocking the road. It was evident that some time would be required to clear up the fall so that coal could be hauled. The miners were on the point of going home, when I and a few others volunteered to have the road cleared in a short time if the diggers would stay and load out their turn, which they agreed to do.

In a short time the track was cleared, but many of the timbers were so badly broken that it was considered dangerous to use the road for hauling, until new timbers could be put in place. Not to throw the mine idle,

however, the driver agreed to take the chance that day and haul the coal, provided the mine foreman would have the place properly timbered the following night. To this the foreman quickly agreed, and the mine ran that day as usual.

But the following morning the road was found to be in the same condition as the day previous, and another small roof fall had occurred. The driver now flatly refused to haul coal another day with the road in that condition. His action forced the men working in that section to go home for the day, with the result that, of the twelve men who went home only three returned the following day. Four of the men did not come to the mine again for four days, and three of them were absent for two days, while two quit the mine altogether. Thus, there being but three men in, the machine crew also quit.

The incident I have related shows gross incapacity on the part of the mine foreman. As a result of his failure to have the necessary work performed the first night, according to his agreement, that section of the mine, in the following two weeks, produced only 200 tons of coal. Ordinarily there would be produced in the same section 125 tons of coal a day, all of the men working there being good miners.

The Result of the Foreman's Failure

As a sequel to this incident, it may be said that the mine foreman embarrassed his own position. He could not discharge the men who stayed out and did not return to the work promptly when the place was made safe. Such action by the foreman would have led to an immediate investigation by the union, and would have resulted in showing that the mine foreman was himself to blame. He was wise enough to know this and so patiently waited for his men to come back to work. In the meantime, however, the output of the mine was greatly reduced.

As has been stated by a writer signing himself "Loyalty," *Coal Age*, July 13, p. 78, the time has come when "slackers should be brought to feel their responsibility in the great cause, by drastic action of the Government." It is just as important to conscript men to produce food and coal as it is to conscript men for the army.

I am myself under the draft law and will probably be in service this month or the month following. The ruling of the Government compels every man to "work or fight." But a man who works but two or three hours in each shift, when he could employ himself full time, is a slacker of the worst sort, and it would seem that these men are being humored, while many brave hearts fighting at the front are suffering from their neglect. To my knowledge, there are ten of these fellows, hereabout, who have never bought a Liberty Bond or a War Savings Stamp. They tell me they cannot afford to do so, although they are drawing from $100 to $125 each pay.

Here, in the summer, we are face to face with a shortage of coal, and what can we expect the coming winter? The situation calls for serious thought, and measures should be taken at once to avoid what is plainly in store for us if the mining of coal continues at the present rate.

I fail to understand the suggestion made by R. W. Lightburn, July 13, p. 79, namely, to work two 6-hour shifts a day. It certainly would not be feasible to work six hours, then rest six hours, work six hours again and rest the remainder of the time in every 24 hours. Perhaps he means to run two separate crews each working 6-hour shifts. Such a plan would present many difficulties, however, and not the least would be to get the men.

My suggestion is to place competent men in charge of each section of the mine who will be responsible for the blasting and loading of the coal in their section. I believe this plan would be feasible.

Cleaton, Ky. Ostel Bullock.

Letter No. 7—The letter of Thomas Hogarth, Coal Age, June 29, p. 1208, draws attention clearly to an important feature in the coal situation. According to the estimates of the Government, there will be a shortage of 55,000,000 tons of coal next winter, which is an appalling proposition. The suggestion Mr. Hogarth makes, regarding the appointment of a Government inspector having authority to check up men who are not regularly on the job, appeals to me as a good one.

A large proportion of the miners working in Colorado are single men; at least that is the case in the district where I am located. It is a fact, also, that the Colorado miner makes as good if not better pay than miners in any other state. These conditions have developed an abnormal tendency in our miners to take vacations. With the increase of pay the shortage of labor here has increased to a startling degree.

It was hoped that the "work-or-fight" order which went into effect recently would prove to be the much needed remedy for holding men in their places. As a matter of fact, however, few cases have come to my knowledge where the idleness of workmen has been investigated. As before, it is the married men who stay on the job, with little loss of time.

The week point in the situation is the fact that when a man wants to lay off for a time, all he has to do is to quit the mine. He knows full well that it will not be difficult for him to get work again at the nearest mine when his money is spent. Thus, an army of competent men whose services are badly needed by the Government are only producing from one-half to two-thirds of the amount they should. The balance of their time is spent in wandering from place to place or is passed in loafing in the saloon.

Questioning Miners Who Quit

For my own satisfaction, I carefully questioned all of the men who left our mine recently. My desire was to ascertain the cause of their leaving. Very few cared to give or could give any satisfactory reason for leaving. Most of them did not try. Some said they "wanted a change," while others "wanted a rest," adding that they "might be back later on."

No doubt Mr. Hogarth's "Government inspector" could easily check up the idleness of men who were not in their places, and this would have a good effect. It would be difficult, however, for such an inspector to ascertain how much time was spent in idleness by men who quit their places in one mine to seek work elsewhere; or to ascertain how long men applying for work had actually been idle.

In order to compete with this feature of the situation some such special means would have to be adopted, as I believe has already been mentioned in the columns of

Coal Age, of giving discharge cards to men leaving a place, and requiring them to show such cards of honorable dismissal when applying for work in another place.

Allow me to draw attention to the fact that the loss in production, due to the idleness of miners, is not the only loss to the mines. There is a very considerable loss in the efficiency of operation when men are constantly coming and going in a mine. Newcomers must become familiar with their places and the conditions surrounding their work before they can show the same efficiency as in the mine they left.

Delay Caused by Breaking In New Men

A new man may be a first-class timberman, but someone must go around with him to show him the places where he is to work, until he knows the roads and can find them himself. A new driver must drive with caution until he has learned his runs. Likewise, an experienced miner must learn the local conditions in a seam before he can load his usual amount of coal each day. A new man going into a strange place must spend a day or more in fixing up his room ready for work. These changes cause much delay and are a positive loss in the production of coal.

All will admit that any law forbidding a man to quit his work when he wishes would be unjust, except as a military measure. The needs of the Government, however, must be the first consideration and the rights of miners to come and go, at this time, may be properly questioned. It may also be a question whether a miner has the right to choose the place where he shall work, as long as this right of choice conflicts with the duty and obligation of the citizen to his country. A soldier has no right of choice in his service but must go where and when he is ordered. If the work of mining coal was subject to the same restrictions during the period of the war, there would not be the loss of efficiency in the mines and the shortage in production that there is at the present time.

M. M. Watson.

Floresta, Colo.

Sealing Off Fire on Intake

Letter No. 8—In the issue of *Coal Age,* June 22, p. 1173, "Ancora" asks for the best method of extinguishing a fire that has gained so much headway on the intake of a pair of entries driven in solid coal that it is thought best to seal off the fire by building air-tight stoppings.

The sketch given in connection with this inquiry does not show whether these are the main headings driven from the shaft or a pair of cross-entries. In the former case, there is little opportunity of preventing the fire from reaching the upcast shaft, or even to give warning to men who may be in danger, since the smoke and gases from the fire are traveling at the rate of 500 ft. per min., that being the velocity of the air current, in this case.

Having warned the men in danger, immediate steps should be taken to short-circuit the air, at a point outby from the fire, by opening a door or tearing down a stopping as near to the fire as possible. This being done and the material being on hand, I would endeavor to erect a temporary brattice, with shiplap or boards, in the return airway, just inby from the crosscut opened.

On entering the return airway it might be necessary to use men equipped with breathing apparatus, in order to avoid their being overcome by the smoke and gases generated by the fire. The temporary stopping should be set far enough back from the opening to permit of the building of a permanent brick or concrete stopping between it and the crosscut. Do not complete the building of the temporary stopping, but leave it open the width of one or two boards from the roof and hang a piece of canvas over this opening.

In the meantime, a similar temporary stopping should be built, at a corresponding point on the intake airway, and carried up to near completion, as before. Now, close the opening in the return stopping with boards, and at once do the same on the intake. The work of building the permanent stoppings should be commenced immediately after closing the two temporary stoppings. This work should be performed as quickly as possible, the two stoppings being carried to the roof and tightly sealed with clay or mortar.

In building the permanent stoppings, it is important to cut into each rib and the roof and floor a sufficient distance to enable the forming of a tight joint. Safety lamps should be used in performing the work, and the thickness should be such as to give the stopping sufficient strength and make it safe. It is customary to build in a pipe in each stopping, at a point near the roof, for the purpose of ascertaining, from time to time, the condition of the air in the space inclosed.

Condition of Air Behind Stoppings

In answer to the second question asked in the inquiry, if we assume that the first stopping was built on the intake, the air behind that stopping would contain much carbon monoxide (CO), owing to the limited supply of air to the fire causing incomplete combustion. Such being the case, it would be a grave question whether it would be possible to build the return stopping.

My experience at a mine fire that occurred at Nokomis, Ill., May 20, 1918, makes me think that the heat of the fire would result in a considerable fall of roof, which would cover the burning coal and timbers. This was particularly troublesome at the Nokomis fire. But it is estimated that a cubic foot of wood (larch) is capable of producing 31.4 lb. of carbon monoxide (CO), which, at ordinary temperature and pressure, would occupy about 420 cu.ft. of space. This suggests what might be the condition in a limited air supply.

On the other hand, in answer to the third question asked, if the return airway is closed first, the gases formed behind the stopping will be mostly carbon dioxide (CO_2); and these gases, being extinctive and rolling back on the fire, would tend to smother it. There would be less chance of ignition and explosion of the gases taking place, and the work of building the stoppings would be safer.

Thomas English,
Springfield, Ill. Supt., Mine-Rescue Station.

Letter No. 9—[This letter, presented by W. H. Detty, Wilburton, Okla., gives the same method of procedure in extinguishing the fire by building stoppings as has already been described by Matthew Stafford, in Letter No. 6 of the last issue of *Coal Age,* page 188, which it will not be necessary to repeat here.—Editor.]

INQUIRIES OF GENERAL INTEREST

Cause of Brittleness in Mine Rails

Kindly permit me to draw attention to a statement made in a letter by "Trackman," July 13, p. 77. In speaking of the brittleness of rails used in electric mine haulage, the writer of the letter says, "The electric return acts upon the rails to make them brittle." I have read elsewhere the same claim that mine rails are made brittle by the action of the electric current, which passes through them on its return.

Permit me to ask if it is not an open question as to whether the electric return has the effect to make rails hard and brittle. I believe that it is the opinion of most all electrical engineers that the electric current has nothing to do with making the rails hard and brittle; but that this is brought about by the constant hammering that the rails receive from the locomotives and mine cars passing over them. Such a reason seems to me far more credible than the one we often hear advanced in regard to the effect of the electric return.

If it is possible to throw any light on this question, that will help to correct wide-spread opinions, it will be greatly appreciated by readers of *Coal Age*. The question appeals to me as a good one for discussion by electricians, who alone are able to give an intelligent opinion. Let us hope for a good discussion.

C. J. CREVELING, Gen. Supt.,
Blackwood, Va. Blackwood Coal & Coke Co.

Through the kindness of Carl Hering, a consulting electrical engineer of Philadelphia, Penn., and a recognized authority on electrical matters, to whom this question was submitted, we are enabled to present the following information regarding the probable cause of brittleness developing in mine rails. Dr. Hering writes as follows:

"Existing knowledge on the possible effect of the electric current to produce brittleness in steel rails is apparently not yet conclusive and definite. There is little doubt in my mind that the factor of degree also enters the problem, that is to say, certain physical actions will have no effect if they fall below a certain limit, while above that limit a decided effect is produced. A familiar illustration of this is the deformation that takes place when a piece of steel is stretched or bent beyond its limit of elasticity, while, on the other hand, the hair-spring of my watch has, for nearly thirty years, been subjected to reverse strains at the rate of five times a second, without the slightest change taking place.

"The claim has not been demonstrated conclusively that an electric current produces brittleness in the conductor. If true, the effect would probably be worse with alternating than with direct current—and would be small with low-current densities.

"The fact is well known, however, that the electric current exercises a crushing effect on a conductor, which effect I described many years ago under the name of the 'pinch effect,' by which name it is now generally known. This force can become very great, but I think it doubtful whether it would ever exceed the elastic limit of steel, except in the case of occasional high-current rushes that might act like a physical blow on the metal, as this force increases with the square of the current flowing in the conductor.

"Besides the pinch effect, I maintain that the electric current produces also a 'stretching effect' in the conductor; while I feel sure this is true, I do not know that my claims in this regard, published some years ago, have been generally accepted. Quantitatively, like the pinch effect, this force increases with the square of the current. But, since magnetization of *steel* produces molecular stresses, it is quite possible that brittleness may arise from this cause in the steel used in mine rails. There is what is known as the 'aging' of steel in transformers, but I am not sure that this includes any pronounced brittleness.

"Regarding the suggestion that the brittleness of rails is caused by the 'pounding of the cars,' allow me to say that the normal action of car wheels is a *rolling* and not a pounding one. The latter takes place only at joints and where dirt accumulates on the rails, or is caused by flat wheels, and is the exception and not the rule. In the passage of cars over the rails, the rails are subjected to an action somewhat similar to that produced when steel is cold-rolled, in a mill. That process, we know, produces hardening and perhaps a degree of brittleness.

"Experience shows that some steels will stand this crushing action by rolling, while others will fail, which shows that the *quality* of the steel in the rails is an important factor. For example, to take an extreme case, we know that a cast-iron rail would go all to pieces if subjected to the rolling action alone. Therefore, as the quality of the steel approaches that of cast iron, the rolling action of the car wheels will no doubt have a greater effect to produce brittleness than in steel of a quality which will stand this treatment.

"I regret not being able to give you a more direct and satisfactory answer To use a mathematician's expression there are many variables involved that affect the results. An approximately direct answer would be about as follows: If the current density in the rails is low, and there are not too many current rushes, the *electrical effect*, is probably *nil*. The *magnetic effect*, with alternating current, might produce brittleness, though this is not certain. The *pounding* of the car wheels on the rails is too local and exceptional to be the cause; but the resulting brittleness observed in the rails arises probably very largely from the rolling action of the car wheels, which, as I have said, resembles the action when steel is cold-rolled in a mill. Lastly, the *quality* of the steel is probably the most important factor in the development of brittleness in rails.

EXAMINATION QUESTIONS

Mine Foremen's Examination Wilkes-Barre, Penn., Apr. 23, 1910

(*Selected Questions*)

Ques.—What can you suggest for the reduction of accidents from falls of top rock, slate and coal, at the working places?

Ans.—To avoid accidents from these causes, the mine foreman and his assistants should visit all working places at frequent intervals, while the men are at work, and observe carefully that the place is well timbered and there is no loose top or coal that may fall. Strict regulations should be made and enforced, compelling every man to inspect his place when going into it in the morning and to set any needed timber before startting to load his coal. Miners must be instructed to set sprags when undercutting the coal. If a foreman or his assistant finds a place unsafe for work, he must withdraw the men until the place is made safe.

Ques.—Name and describe some of the important differences between the Davy, the Clanny and the Wolf safety lamps.

Ans.—In the Davy lamp, commonly used by firebosses when testing for gas, the oil vessel is surmounted by a wire-gauze chimney, which is generally protected by a metal shield on one side of the lamp. There is no glass cylinder surrounding the flame.

In the Clanny lamp, the oil vessel is surmounted by a glass cylinder that surrounds the flame and permits the lamp to give a better light than is possible with the Davy. The glass cylinder is surmounted again by a wire-gauze chimney, which is shorter than that used in the Davy lamp and frequently surrounded by a steel bonnet to protect the flame of the lamp against strong air currents.

The Wolf lamp, in common use as a working lamp, has practically the same form of construction as the Clanny lamp. One particular feature of this lamp is that the metal bonnet surrounding the gauze chimney is corrugated and has a number of tangential openings for the passage of air, which afford good protection against strong air currents. The distinguishing feature of the Wolf lamp is that it is designed to burn a volatile oil, such as naphtha benzine. The oil vessel is of pressed steel and filled with absorbent cotton to reduce the explosiveness of the oil. The lamp is equipped with a self-igniter.

Ques.—What dangers may arise from the improper assembling of a safety lamp?

Ans.—The improper assembling of a safety lamp means that one or more of the parts have been omitted or the several parts have not been accurately fitted to each other. In each case there is opportunity for the burning gas to pass between the imperfectly fitting parts and ignite the gas-charged air surrounding the lamp when the latter is exposed to gas in the mine. In other words, the flame of the lamp is not isolated from the outside atmosphere, and the lamp is no better than an open light.

Ques.—A slope measures 4.6 in. in length, on the mine map; the tidal elevation at the top is +780 ft., and at the bottom +530 ft.; what is the length and grade of the slope?

Ans.—Assuming the map is drawn to a scale of 100 ft. per inch, the horizontal length of this slope is $100 \times 4.6 = 460$ ft. The difference of elevation between the bottom and the top of the slope, or the rise of the incline in 460 ft. of horizontal distance, is $780 - 530 = 250$ ft. The length of the slope is found by extracting the square root of the sum of the squares of the horizontal distance and the vertical rise. Thus

$$\sqrt{460^2 + 250^2} = 523.5 \text{ ft.}$$

The grade of the slope expressed as the vertical rise per horizontal distance is 250 : 460 or 1:1.84. The percentage of grade, or the rise per 100 ft., is $100 \div 1.84 = 54.3$ per cent.

Ques.—What precautions would you suggest to guard the employees in a mine from possible accident due to the use of electricity?

Ans.—All electrical installations should be made by a competent mining and electrical engineer. The power line and trolley, as far as practicable, should be kept off from travelingways. At all points where it is necessary for men and animals to cross the haulage road. or to pass under a power line, the conductor should be protected in a suitable manner to avoid accidental contact. Wherever it is necessary to install live wires on a travelingway, the conductor should be carried on one side of the passage and suitably guarded.

All conductors should be firmly attached to the mine timbers and carefully inspected at regular intervals. Danger signals should be posted at all points where live wires are exposed, and a suitable warning should be posted at the entrance to the mine, cautioning all persons to avoid the danger of contact with live wires in the mine. Where power is used to drive machines at the working face, competent machine runners should be employed who should be instructed to take every precaution against accident to their helpers..

Ques.—Describe the various methods of propping and timbering slopes, gangways and chambers in anthracite mines.

Ans.—Methods of timbering will always depend to a large extent on the nature of the roof, floor and sides of the opening. Under fairly good roof, where the seam has little or no inclination, post timbering is used in chambers and double timbering on the entries. The crossbeams or collars are often hitched into the ribs or supported on short legs toed into the ribs where the coal is hard. Lagging is used over and behind the timbers to give needed support between timber sets where roof and coal are weak. In slopes and in inclined headings and chambers all posts and timber frames are inclined up the pitch a few inches from the normal, depending on the degree of the pitch.

COAL AND COKE NEWS

Harrisburg, Penn.

That the coal miners of the anthracite region are not seeking exemption was demonstrated when the district draft board of Shenandoah attempted to force exemption on a number of mine workers who appeared at the railroad station on July 23 to go to Camp Lee. Two of them knocked down officers who tried to prevent them from boarding the train taking soldiers to camp. Others climbed through car windows, while many left in automobiles for Mahanoy Plane, where they caught the train.

Despite exemption claims filed by the Lehigh Coal and Navigation and other companies in the Schuylkill and Panther Creek valleys, 69 selectives left on July 23, only two less than the full quota. Few of the mine workers will stand for the coal companies' exemption pleas, their claim being that other men can take their places.

At Plymouth, Luzerne County, 21 men on the same date were informed that the coal companies and the Government requested that they be held back as skilled mine employees. The draftees in all these cases had made all preparations to depart and consequently lost a number of days' wages. They have asked that an official slip be issued stating that they came prepared to go to camp, and through no fault of their own were held back by the Government.

The action of draft boards is an aftermath of the meeting held recently at Wilkes-Barre, when Major Conklin, of Provost Marshal Crowder's staff, stated that the boards had authority to place the men in deferred classes on a petition of the coal companies.

Despite the efforts made to keep production rising in the Connellsville regions, the output fell off considerably during the week ended July 20, according to figures made public by the Fuel Administration. Coke production for the week was 347,488 tons, a drop of 808 tons over that of last week's record output, and coal dropped from 168,587 tons last week to 161,140 tons the week just ended.

Car supply for the week was excellent, and idleness on the part of a certain percentage of the men is the only reason that can be assigned for the slump. The Fuel Administration order for a daily check upon the labor slacker is making itself felt, and a noticeable increase is expected in this week's figures.

The scope of the "six-day" order was widened this week when requests were directed by the Fuel Administration to mayors and burgesses of every town in the district asking for coöperation in its enforcement. The authorities are asked either "to run in or run out" any able-bodied men found in their district who have no regular employment.

Although much disappointed with last week's production, Fuel Administration officials take an optimistic viewpoint of the situation and believe that the measures already taken to arraign labor solidly behind the war program will result in appreciable gains in the output within a short time.

Charleston, W. Va.

Production fell off in the Kanawha district during the third week in July, though it was kept above the 200,000-ton mark, the total net tonnage produced being 201,677, as against 205,000 plus for the previous week. Two factors are believed to have contributed to the decrease—loss of power for one day and labor shortage, as mine disability for which lack of power was entirely responsible resulted in the loss of 740 hours—much more than is usually the case. Labor shortage was responsible for 795 hours of lost production. It will also be observed that only 5831 hours were worked, a considerable reduction from the second week in July. It is believed, however, that the total production for July in the Kanawha field will be in excess of that for June.

In the last week there has been a most decided slump in the car supply for the Fairmont field, the number of cars not averaging much over 900 cars a day, which is almost half of the normal requirements. It is said that the slump is approaching an acute stage. It appears that wrecks and derailments, and not the system of distribution, are responsible for conditions in the Fairmont region. Last Tuesday, of 167 mines reporting, 17 were shut down and the number of men idle because of insufficient cars was 1860, resulting in a tonnage loss of 18,345 tons, the cars on hand only amounting to 931, 61 of them being for coke shipments.

That wagon mines, or the so-called "snow-bird mines," are to have recognition was made plain by Dan Howard and other members of the temporary organization committee of five of the Northern West Virginia Coal Operators' Association, who publicly announced that the "snow-birds" were to have proper and fair consideration in the affairs of the new association. The "snow-bird" mine is coming into its own apparently, since it is now recognized that acres of coal which would have otherwise been left untouched have been mined and have helped supply the market. While many of the railroads have put many obstacles in the way of the development of the wagon mines, the Kanawha & Michigan is not one of that class, as it supplies all of its wagon mines with plenty of cars.

Terre Haute, Ind.

Mines in Indiana, for the week ended July 13, hoisted 651,928 tons of coal, according to a statement issued by the Indiana Bituminous Coal Operators' Association. The best previous weeks were in June, when in each of two successive weeks 621,000 tons were mined. Production the week ended July 13 was assisted by the larger number of mines working, the total number being 189. The increase was caused largely by the reopening of several properties on the Southern R. R., which now serves sixteen mines. Car supply was more satisfactory, the total car shortage being only 6.07 per cent. Several of the more important coal roads had a 100 per cent. car supply. The additional tonnage possible with this full car supply was 58,220 tons. The shortage on the Chicago & Eastern Illinois was only 0.96 per cent. and the Chicago, Terre Haute & Southeastern 0.36 per cent. The Pennsylvania had a shortage of 14.45 per cent., the Southern of 20.96, and the Illinois Central of 16.93 per cent. Three large mines at Linton were closed most of the week because the miners refused to work after a train schedule was changed.

PENNSYLVANIA

Anthracite

Hazleton—The Lehigh Valley R.R. has been directed to take the coal of the Coleraine mines to market, this action barring the Philadelphia & Reading R. R. from one of the oldest and richest collieries in the Lehigh field.

Shamokin—The Jones Coal Co., lessees of vast tracts of culm about the Mahanoy Plane, will this week place in operation a model washery and plans to ship from 350 to 600 tons of the smaller sizes of coal to the eastern markets each day. The new operation will be electrically operated.

Sunbury—After a trial which lasted eight weeks, W. C. Moulton, a Scranton coal operator, on July 19 won a verdict against the Philadelphia & Reading Coal and Iron Co. in a suit which involved the ownership of culm banks in Zerbe township, Northumberland County, said to be worth $2,000,000. Moulton alleged he had good title through unseated land-tax sale deeds, while the defendant claimed a clear deed from an original grant to William Penn.

Hazleton—A new ruling on the status of men working about the mines was established on July 22, by the district appeal board of Scranton, in refusing deferred classification to Howard Zullick on industrial grounds. Zullick is employed as a clerk at the Lattimer mines. The appeal board has ruled that clerks and stenographers about the mines are not essential workers and do not come under the recent ruling of the draft officials that mine workers are not to be taken.

The Charles Kehoe & Co. strippings on the Sayre tract of the Lehigh Valley Coal Co., near Mt. Carmel, and the Packer No. 5 operations on Lehigh Valley land at Shenandoah, were sold recently to the Rhoades Construction Co., of Ashland. The purchase covered both equipment and contracts which have many years to run. The Kehoe concern has now disposed of all its holdings outside of the Hazleton basin and will devote its entire attention to the local field.

Pottsville—Philadelphia and New York capitalists are forming a new corporation in this region for the purpose of washing anthracite culm out of the rivers in this vicinity with sluices and flumes, much as is done in gold camps in Alaska. About 100 washeries employing this new method and also the old system of washing culm from dirt banks are to be established, nearly all in this county, with some in Northumberland County. A number of new washeries are to be built along Mahanoy Creek, where there are millions of tons of culm at convenient points.

The greatest war garden in Schuylkill County is being conducted by the Philadelphia & Reading Coal and Iron Co., which has planted a vast tract near the Broad Mountain with corn, wheat, etc. A good crop is in prospect. Many other tracts owned by the company have been leased free of charge to employees. The company is making an effort to have this great mining district show that it not only can furnish this state and many adjacent states with coal, but also supply its own food. A number of years ago the miners of this region raised a considerable portion of their own food products, in gardens adjacent to their homes. An effort is being made to get back to these conditions.

Bituminous

McIntyre—The tipple of the Coal Run Mining Co. for mines Nos. 1 and 3 has been remodeled and enlarged. The railroad company has made additional sidings above the tipple to accommodate increased car facilities.

Somerset—The Orenda Smokeless Coal Co. recently purchased the holdings of the Merchants' Coal Corporation, of Boswell, for $2,000,000. This is the largest deal in this county in some time. All the operations in the Boswell fields are involved.

Uniontown—Four coal miners were killed instantly when they were crushed beneath a fall of slate in the Penn. Coal Co.'s mine at Smithfield on July 19. The dead are George Epley, Arthur Conn, James James and Albert Collins. Officials of the company state that the four men were working together in one section of the mine when the accident occurred. A score of miners worked more than 24 hours before the wreckage was cleared.

West Lebanon—J. C. McGregor, Dr. H. B. Puterbaugh, of Indiana, and Harry E. Clark, of Glen Campbell, have purchased 1200 acres of the Pittsburgh seam of coal between South Bend and Elderton. The consideration was about $40,000. No announcement has been made as to the development of the property.

Washington—Dr. George M. Kelly, of this place, recently sold to the Pittsburgh Coal Co. 92.591 acres in the Pittsburgh or river vein of coal underlying a tract in Canton township for a consideration of $27,777.30, or about $300 an acre. The coal in question fronts on the West Middletown road and adjoins Wolftown, just northwest of Tylerdale.

Indiana—The Manufacturers Coal Co. controlled by an Eastern manufacturing company, is opening new mines on the north side of Yellow Creek, near the present operations of the Meco Coal Co. It is understood that the coal will be used exclusively at the Eastern factories of the company. The mines are located on the Yellow Creek branch of the Pennsylvania Railroad.

Patton—The tipple of the Pennsylvania No. 39 colliery of the Pennsylvania Coal and Coke Corporation, near here, was de-

stroyed by fire last week. Incendiarism is given as the cause, and the company has offered a large reward for the arrest of the persons setting the building on fire. A temporary tipple has been erected and will serve the operation until a large structure can be built.

Berlin—John and Robert Groff have leased 20 acres of the J. O. Stoner 6-ft. vein of coal. They have begun two openings and are into the coal. The coal is under the field north of Stoner's grove, and the drift mouths are a few rods from the end of the railroad track above the Baltimore & Ohio R. R. station. For the present the mines will be operated as wagon loaders, but arrangements may be made later to install a tipple.

Uniontown—C. G. Rockwell, an attorney, of Chicago, this week exercised options taken upon 5000 acres of "back" coal in Whitely and Franklin townships, Greene County, with the initial payment in the $2,000,000 deal to the trustees in bankruptcy of Josiah V. Thompson, former coal baron and banker, now the principal figure in what has been termed the largest bankruptcy case in history. The identity of the purchasers has not been disclosed, but it is likely that the information will be revealed with the proceedings before Referee in Bankruptcy J. G. Carroll. The purchase price in this, the second largest deal in the liquidation of Mr. Thompson's tangled affairs, averages $350 per acre.

WEST VIRGINIA

Page—With a large force of men at work on the completion of a side track from the VirginianRy., the Beaver Fork Coal Co. expects to be able to begin the shipment of coal in the near future.

Princewick—With machinery already on the ground ready to be set up, a conveyor and picking tables will form a part of the new equipment of the Princewick Coal Co. at this place, added in order to secure cleaner coal.

Charleston—Another mine is being opened by the Mead-Pocahontas Coal Co. and the company hopes to begin mining and shipping coal in about 60 days. The general manager of this company is J. C. Sullivan, of Tralee.

Logan—A conveyor system is soon to be installed by the Fire Creek Smokeless Coal Co. at Lego, in Raleigh County, enabling the company to clean its coal with facility. The company also expects to let the contract soon for the construction of a number of houses for miners

Fairmont—Jamison mine No. 7, where a terrible explosion occurred in 1916, has been the scene of activity the major part of the time since the accident. J. M. Wolfe, superintendent for the West Virginia interests of that company, announces that the work of recovery will be completed by Sept. 1.

Worthington—The Worthington Coal Co. has closed down its mine on account of the car supply. But one car was received during the week ended July 13, and it was impossible to hold the miners. Perry D. Burton was the manager, and his employees were taken to another mine operated by him near Monongah.

Welch—Operations on a large scale will be undertaken by the Middle West Coal Co., which has been organized with a capital of $200,000, the seat of operations to be in McDowell County. Those chiefly interested in the organization of the company are Eugene H. Popinsky, Simon Solin, Harry Kline, Nathan Goodman and Harry Bank, all but Bank, who lives at Kimball, being at Welch.

OHIO

Aetnaville—The Koehnline coal mine here has resumed operation after an idleness of more than a year while undergoing extensive repairs. The mine is said to be in the best possible condition, and it is expected to increase the output.

Martins Ferry—The Y. & O. Coal Co. has completed arrangements for opening up a tract of between 10,000 and 15,000 acres of coal land near Connersville, a few miles north of here. The Y. & O. company has extensive holdings in Belmont County, with several mines already in operation.

INDIANA

Brazil—Chicago & Eastern Illinois R. R. officials have denied cars and switching privileges to the W. C. Nash coal mine, near Clay City, on the ground that the operation was not producing enough coal. Mr. Nash is arranging to open a new mine on the Charles Cooprider farm, near Clay City, in a short time.

Terre Haute—Edward Stewart, of Terre Haute, Ind., president of the United Mine Workers' District No. 11, has announced that he has decided not to accept the appointment as state mine inspector, which position was recently offered him by the Indiana Industrial Board. He said that he thought he could do more good in the present national situation by keeping his present place. District No. 11 includes the greater part of Indiana.

Linton—About 675 miners, who have been out on a strike for seven days because of a change in the schedule of a miners' train leaving Linton daily, have returned to work after the Indianapolis and Vincennes Railroad Co. had restored the former schedule. The miners struck because they claimed that the change put an extra hour on them daily in going to and from the mines. Most of the miners worked for the Vandalia Coal Company.

ILLINOIS

Peoria—The failure of the Consumers Coal Co., of this city, to execute a contract given it by the City of Peoria has caused the Council to issue instructions to the city clerk advertising for new bids.

Mt. Vernon—As a result of a strike of employees of the Wabash, Chester & Western R. R., which operates between Mt. Vernon and Chester, four coal mines served by it have been temporarily forced to suspend operations.

Panama—It is said that William McDonald, recording secretary of the Panama coal miners' union, is missing after a warrant had been issued charging him with forgery. It is charged that McDonald, while acting as recording secretary, forged the name of Peter Smith, the treasurer and the president of the local, to orders which he cashed, and thereby secured possession of about $1100 from the funds raised by the miners of Panama to be given to the Red Cross and other war relief work. Officers have been looking for him since about the Fourth of July. Auditors have been placed at work on his books.

McLeansboro—The drillers at Dale, Ill., have reached a depth of over 500 ft., and the prospects are good for a rich vein of coal. If coal of sufficient quality is found, a shaft will be sunk and a mine will be placed in operation just as soon as material and machinery can be installed.

Decatur—No coal has been shipped out of Macon County, but there is strong local demand for the output of the mines. On a recent day 35 teams were noted waiting at the mines. The mines are now running from three to six weeks behind in their orders, all of the coal being used in Decatur and vicinity.

Pana—The Penwell Coal Co. hoisted for the year ended June 30, 1918, a total of 315,870 tons of coal. The car supply for this mine was good, and but little time was lost by the miners. The Pana Coal Co., operating two mines in the same general field, hoisted 352,900 tons of coal, although the hoisting at the North mine was not begun until Jan. 15, 1918. There has been a good demand for coal from both the Penwell mine and the Pana mines.

Carlinville—The Standard Oil Co. has begun sinking the shaft for its No. 3 mine here. The company first purchased the Carlinville mine, which it named No. 1, and then opened No. 2. No. 3 will be completed as soon as possible. A fourth mine, not as large as the others, is also to be opened in October. In Mine No. 2 quantities of quicksand have been encountered which have hindered operation. It is feared that work in this mine will have to be stopped for a time unless a way is quickly found to control the quicksand. A power house costing more than $1,000,000 is under construction at Mine No. 3, which will furnish electricity to all the company's mines.

Harrisburg—The Saline County Coal Co.'s No. 2 mine, known as the "Steel Tipple" mine, has recently been awarded a large flag in honor of the fact that every employee at that shaft is the owner of a Third Liberty Loan bond. R. O. Burke, chairman of Saline War Savings Stamp Committee, made one of the addresses at the raising of the flag and told the miners that if they would make a 100 per cent. record in the purchase of War Savings Stamps that he would personally guarantee them a flag in commemoration of that feat also. The men are making an active canvass of the mine and selling stamps to every employee. In fact, that district known as West Ledford, in which this mine is located, has already sold about $8000 worth of stamps and hopes to make it $10,000. The quota is $9750.

OKLAHOMA

Howe—After being idle for more than 15 years, the 100-oven coke plant built here in 1899 and 1900 by the old Mexican Gulf Coal and Transportation Co. has resumed operations. The property was bought last December by the Howe-McCurtain Coke Co., operators of the coke plant at McCurtain, Okla. Included in the deal was 4000 acres of coal lands. The new operators propose to enlarge the plant as soon as possible and to materially increase its present daily capacity of 125 tons.

TEXAS

Dallas—Headquarters of the Standard Petroleum and Coal Co. has been moved from Mount Pleasant, Texas, to Dallas, and established at 1209 Great Southern Building. B. W. Williams, president of the company, will move to Dallas and take charge of the office. The company owns extensive coal and oil lands in Titus and other east Texas counties, and is preparing to operate on a large scale.

WASHINGTON

Chehalis—The Superior Coal Co. has closed a contract for supplying 200 tons of coal a day to interests in Portland. It has doubled its working force and is laying plans for new development work at once.

Centralia—A fire which broke out in one of the crosscuts of the Mendota Coal and Coke Co. mine has temporarily closed it down.

Foreign News

Victoria, B. C.—In a memorandum issued on July 17 by Charles W. Peterson, deputy fuel controller for Canada, it is announced that Winnipeg is to have 65 per cent. of its normal supply of anthracite coal next winter, while the remainder of the Province of Manitoba other than the City of Winnipeg, and that portion of the Province of Saskatchewan east of approximately the 104th meridian, is to have 50 per cent. of last year's consumption. To the cities of Moose Jaw, Regina and Saskatoon 50 per cent. of last year's consumption is allotted.

Vancouver, B. C.—Shipments of coal from its new coal mines at Cassidy Landing to the bunkers of the Canadian Collieries at Ladysmith have been started by the Granby Mining, Smelting and Power Co., and will continue for the present at the rate of 100 tons a day. This will be increased as the operations at the mine permit. The coal will be stored at the bunkers until the by-products plant at Anyox is ready to receive it, which will be several months, in all probability. Meanwhile work on the company's own bunkers will proceed. Reports from Anyox indicate that work is being rushed on the byproducts plant, the coke ovens now being in course of construction. With its own coal mine and coke plant the company will be assured that it will have available sufficient coke for the smelter and will not suffer from shortage as was the case last year when labor troubles in the Crows Nest district interfered with the output of coal, causing a corresponding depletion of the coke supply at the smelter at Grand Forks.

Personals

H. J. Kennard has resigned as superintendent of the mines of the Coal Run Mining Co. at Kent, Penn.

H. B. Stamper has resigned as superintendent of the Jacksonville Nos. 1 and 2 mines of the Jefferson and Clearfield Coal and Iron Co., at McIntyre, Penn.

Matthew Lewis, formerly of Holsopple, Penn., has taken charge of the United Smokeless Coal Co.'s operations at Humbert, Somerset County, Pennsylvania.

Thomas Hogarth, formerly superintendent of Coal Run Nos. 4 and 5 mines, has been promoted to superintendent of all the mines of the Coal Run Mining Co. Nos. 1 to 7, at Kent, Penn.

A. M. Ogle, of the Fuel Administration, has been spending a couple of weeks in the field. During his absence, C. G. Hall, the district representative for Indiana, has been handling Mr. Ogle's work in Washington.

Spencer Ewing, formerly fuel administrator of McLean County, Illinois, has recently been appointed Director of State Requirements of the State Administration of Illinois. The Bloomington Coal Dealers' Association passed resolutions commending the faithful and impartial services of Mr. Ewing while fuel administrator of McLean County.

A. Yule of the Pioneer Coal and Coke Co. of St. Louis, Mo., is now an assistant to A. W. Calloway in the distribution of smithing coal. He is the first St. Louis coal man to be taken to Washington in connection with the Fuel Administration.

Obituary

John L. Schmidgall, age 47 years, for many years a prominent operator in the Murphysboro (Ill.) field, died in a St. Louis hospital on July 21 after a long illness. He was a graduate of Washington University at St. Louis and for several years was a civil engineer. Later he took charge of his father's extensive affairs, including the Schmidgall mine. The deceased was a member of the State Mining Board some few years ago and was mayor of Murphysboro for the years 1909 and 1910. Besides a widow, he leaves three sons.

Industrial News

Sullivan, W. Va.—The Sullivan Coal and Coke Co. is planning to increase its output from 500,000 to 1,000,000 tons per annum. The plant will be enlarged.

Hazleton, Penn.—The Lehigh Coal and Navigation Co. is planning to enlarge its works for the manufacture of coal briquettes, to provide for increased output.

Hazleton, Penn.—The Lehigh Valley Railroad Co. will increase the capacity of its mixer plant to provide for the blending of small anthracite coal with bituminous for locomotive service.

Stearns, Ky.—The Kentucky & Tennessee R. R. Co., of Stearns, operating in a rich timber and coal belt, where a number of big mines are operating, has increased its capital stock from $25,000 to $625,000.

Houston, Tex.—J. B. Adone, of 436 Westmoreland Boulevard, is planning the development of extensive lignite properties and would like to get in touch with producers of all kinds of mining machinery and equipment.

Jersey City, N. J.—The Central Railroad of New Jersey has awarded a contract to the General Contracting and Engineering Co., 29 Broadway, New York, for the construction of new reinforced-concrete coal pockets at its local terminal.

Oakdale, Ohio—Emmet Riley has leased a tract of 160 acres from the Buckeye Coal & Ry. Co., located on the Zanesville & Western railroad near Glouster. Plans have been made to drive an entry and open a mine to produce about 300 tons daily.

Gooding, Ida.—The Oregon Short Line has been authorized by the Federal Director of Railroads to construct a 12-mile spur track to the Teton coal fields, which are to be fully developed by the Teton Coal Mining Co., of Coeur D'Alene, of which R. C. Talbot is manager.

Greendale, W. Va.—A deal has been closed whereby the Greendale Mining Co., has sold its operating mine at Greendale to the Dollar Coal Co., of Cincinnati, which will make improvements and extensions and operate it in the future. The present capacity is about 300 tons daily.

Sassafras, Ky.—The Montgomery Creek Coal Co., recently incorporated with a capital of $100,000, has perfected its organization and is said to be planning for the early development of about 1000 acres of coal properties in this district held under lease. J. W. Reedy, of Lothair, is president.

Seattle—The Seattle School Board is considering an offer of the Pacific Coast Coal Co. to install coal burners in the schools here for burning powdered coal for heating purposes. All schools which were until the first of the year equipped to burn oil have been changed to coal burners.

Newark, N. J.—Until 1.30 p.m., Aug. 7, the Board of Freeholders will receive bids for the construction of reinforced-concrete coal pockets, including the installation of coal conveying machinery and equipment, at the Essex County Hospital, Overbrook. Runyan & Cary, 845 Broad Street, consulting engineers.

Louisa, Ky.—It is reported that the Louisa, Fort Gay & Torchlight Coal & Development Co., capital $1,000,000, organized by C. E. Stafford president, and others, plans the development of coal lands, the operating of ten collieries, construction of ten miles of railroad, and also the building of a central power plant on Lick Creek.

Charleston, W. Va.—Tracts of coal lands in Clay and Nicholas Counties will be developed by the Gauley Coal Co., which has been chartered with a capital stock of $100,000. Those principally interested in this company are Mat Levy, M. E. Moore, Louis Levenson, Elmer G. Biddison, Lemual A. Maxman and Louis Levy, all of Charleston.

Mortonville, Ohio—The Buckeye Coal & Ry. Co. has leased to William M. McCracken of Lancaster, O., a tract of 160 acres of No. 7 coal near Mortonville, which he will open by driving an entry. Electrical power will be secured from the Mortonville power plant of the Buckeye company. It is planned to equip a mine to produce 350 tons daily.

Charleston, W. Va.—The Marmet-Oliver Coal Co. will operate mines in Kanawha County, and with that end in view has secured a charter under which a capital stock of $50,000 is authorized. Those principally interested in the new company are Edwin Marmet, Thomas Oliver, V. L. Black, John Wehrle and S. P. Richmond, all of Charleston.

Piedmont, W. Va.—Holdings of the Fredlock Coal Co., of Piedmont, in Preston County, will be developed by that company, which has been chartered with a capital stock of $10,000, the incorporators being Frederick W. Fredlock, Jessie R. Fredlock, Robert McV. Drane, of Piedmont, Louis Adams and C. C. Culbertson, of Westernport, Md.

Charleston, W. Va.—Coal in the No. 2 gas seam on Campbell's Creek, in Kanawha County, will be mined by the Dana Coal Co., which has been organized and chartered by H. A. Jepson, of the American Rolling Mill Co., Marting, W. Va., with an authorized capital stock of $100,000. Offices will be maintained in the Union Building, Charleston.

Charleston, W. Va.—An acreage of coal in Elk District, Kanawha County, will be developed by the Liberty Coal Mining Co., recently incorporated with a capital of $10,000, the incorporators being B. M. Smith, J. A. Thomas, J. V. Sullivan, W. E. Whiteman and C. A. Wood. It is stated by one of the incorporators that work will be begun in about two weeks.

Oakland, Md.—The Freeport Coal Mining Co., a corporation engaged in mining near Corinth, W. Va., will increase its capital stock from $25,000 to $100,000, and has let the contract for extensive improvements and construction work on its property. The sole owners are Messrs. Campbell and Hoffa, of Piedmont; F. A. Thayer and Herman Creutzburg, of Oakland; and George Warnick, of Bloomington.

Clarksburg, W. Va.—Another mining operation in Harrison County will be established by the Diamond Fuel Co., this company owning a tract of coal in Simpson District. With a view to producing coal on a large scale, the company has been chartered with a $50,000 authorized capital stock, the incorporators being Paul E. Reutter, Wayne B. Hornor, Chas. B. Johnson and Carl Hornor.

Uniontown, Penn.—An order has been issued in United States District Court directing the immediate sale of 3000 shares of the Liberty Coal Co. and 7000 shares of the Wetzel Coal and Coke Co., both West Virginia corporations, to liquidate J. V. Thompson's indebtedness to the First National Bank. The indebtedness approximates $800,000, while the two blocks of stock have a reputed value of $1,700,000.

Decatur, Ill.—It is estimated that Decatur industries will store this summer at least 100,000 tons of coal. The largest consumer is the Wabash Railway Co., which is placing between 30,000 and 35,000 tons of coal in storage for next winter. The Decatur Railway and Light Co. will store 5000 tons of coal, and there are a score more of industries which will lay in from 500 to 15,000 tons each.

Sebree, Ky.—N. O. Tyler and J. M. Anderson, of Birmingham, Ala., representing the New Sebree Mining Co., recently incorporated with a capital of $100,000 with headquarters at Hopkinsville, were recently in Sebree looking over the old Sebree coal mine, of the Sebree Mining Co., which has been purchased. It was stated that improvements would be made at once, and the mine would be shipping coal again before cold weather.

Springfield, Ill.—State Fuel Administrator Williams of Illinois has announced that the allotment of anthracite to Illinois shall be divided on an equal percentage basis among the thirteen northeastern counties of the state — Stephenson, Winnebago, Boone, McHenry, Lake, Ogle, De Kalb, Kane, DuPage, Lee, Kenall, Will and Cook. The distribution will be on the basis of about 80 per cent. of the consumption in 1916 and 1917.

Hazard, Ky.—Coal operators of Perry County feel that they did good work when during the fiscal year ending June 30, 1918 they showed 1,618,353 tons of coal mined as compared with 998,000 tons during the preceding year. This is a healthy increase, but the operators claim they will surpass it this season if the labor supply holds up anywhere near requirements. A number of good mines, well equipped, are operating in the section, and these operations are keeping up with modern methods.

Alton, Ill.—Utilization of the Alton river terminal for the landing of coal on barges is contemplated in the plans of M. V. Sanders, Federal Inland Waterways Manager, who has charge of the establishment of barge service on the river. The terminal, which was equipped with hoisting apparatus, will enable the loading of great quantities of coal direct from cars to barges to be transported up and down the Mississippi. A. W. Mackey, of St. Louis, Sanders' assistant, will inspect and determine to what extent it can be used.

Charleston—D. H. Morton and associates of Burnwell, Raleigh County, have organized the American Eagle Colliery Co., and plan to expend $300,000 in the construction of a plant in Raleigh County, the mine to be a drift mine. It is estimated that the capacity of the new plant will be 300,000 tons a year. Work on the new plant will start shortly it is said. The Colliery company has been incorporated with a capital of $600,000, the incorporators being G. S. Couch, V. L. Black, L. G. Summerfield, Angus W. McDonald and S. L. Boriarsky, of Charleston. The superintendent of the new plant is to be Holmes Morton, who is located at Burnwell.

Indianapolis, Ind.—It is probable that fourth vein coal, the best grade of coal taken from Indiana mines, will be taken from the market, except for certain industrial plants engaged in work essential to the prosecution of the war and which can use no other grade of coal. A prediction to this effect was made by R. L. Flood, of the Quartermaster's Department of the United States Army, who was assigned to Indiana to supervise the establishment of preference lists for industrial plants engaged in war work and to work in coöperation with the state fuel administrator. Fourth vein coal is scarce, and this has caused the Federal Fuel Administration to desire to husband it closely.

Chicago, Ill.—The Chicago & Alton R. R., which is handling an immense amount of coal into Chicago for both city consumption and for delivery northward, has lodged a protest with the Cook County fuel administrator saying that receivers of carlots of coal have failed to unload consignments promptly. The Alton officials are keeping a sharp lookout for receivers who fail to unload their coal as soon as they should, and a systematic check will be kept on the failure of these men to send cars back. The Alton has received five new locomotives from the Baldwin locomotive works, and with the new engines assigned it by the Government will be able to move a vast tonnage of coal as well as of other commodities.

Columbus, Ohio—The State Public Utilities Commission has secured from the Supreme Court a writ of mandamus to compel the Morgan Run Coal Co., operating a three-mile railroad in Coshocton County, to furnish service to other coal mines on the line than that owned by the company. The proceedings resulted from complaints by other operators with mines on the road that service was refused them by the Morgan Run Coal Co., the latter defending on the ground that it was not a common carrier. The Commission, after a hearing, held that the road was a common and not a private carrier, and ordered the company to furnish car and transportation service to other mines on the line, but the company refused.

Fort Wayne, Ind.—Coal dealers of this city, when asked by their county fuel administrator to lay in large supplies of coal, appealed to their local banks for credit with which to purchase the coal. The banks asked for a statement of how much money was due the coal companies from delinquent customers. A list was prepared, taken from the books of the dealers, and it was found that there were 4000 consumers in Fort Wayne who owed the dealers $140,000. The fuel administrator says that he will permit no dealer selling to any delinquent customer of any other dealer, and that all those in arrears will be denied coal. The delinquents who pay their old bills can secure coal from any dealer. The administrator is preparing to store 25,000 tons of coal for emergency purposes next winter.

MARKET DEPARTMENT

Weekly Review

Market Generally Optimistic—Production Heavy But Not At Record—Stocks Accumulating in Certain Instances—Lake Movement Heavy

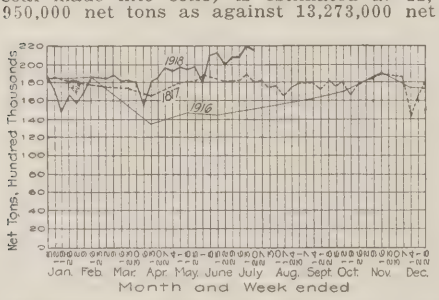
THE week's coal production while not establishing any new records has been heavy, closely approximating the best week the country ever experienced. Car supply has also been good, in some few cases equaling or even exceeding requirements. The accumulation of stocks is gradual and most pronounced in the case of the domestic and small industrial consumer. Railroad stocks are increasing with slowness as are also those of big industrial consumers.

The householders on the other hand are accumulating their winter's supplies and it is probable that by cold weather there will be but few that ordered their coal last spring that will not have a supply sufficient to carry well into the winter.

Recent fear of congestion at various points, particularly in New England, has arisen more from a shortage of labor wherewith to unload cars than from lack of motive power. A greater variety of cars than formerly are also being employed in the coal trade and the use of other than dump bottom cars is occasioning considerable inconvenience. No one thinks of entering complaint, however, as all dealers and consumers are glad to get the coal irrespective of the car it is shipped in.

The Lake trade is heavy and it is probable that there will be no greater shortage in the Northwest during the coming winter than there was during the past.

In the Middle West some coal has been sold at less than the Government price. This is perhaps significant of the position that coal occupies in the market. Since the Government prices went into effect it has been seldom indeed that coal has been sold in the open market for less than the Government figures.



The car supply, taking the country as a whole, appears to be somewhat better than in some past weeks. In some localities in the East the car supply has been fully equal to the demand, while in Illinois some mines have only been able to work about three days per week. Much complaint is heard concerning this car distribution.

Because of railroad and navy demands for gas coal some illuminating gas companies are experiencing difficulty in securing supplies. Coal has been shipped all the way from western West Virginia to New England for this purpose. It is believed, however, that any great quantity of this coal will not be shipped such a distance for this purpose.

The demand for coal is everywhere brisk with supply just about equaling the demand. Production is heavy, car supply in general fair and individuals and small industrial consumers are beginning to get small stocks ahead.

COAL PRODUCTION

Production of bituminous coal during the week of July 20, while not equivalent to the record week of July 13, was higher than any previous week. The output during the week ended July 20 (including lignite and coal made into coke) is estimated at 12,950,000 net tons as against 13,273,000 net

tons during the week preceding, or a decrease of 2.4 per cent. and as against 11,230,000 during the corresponding week of 1917, or an increase of 15.3 per cent. The average production per working day during the week of July 20 is estimated at 2,159,000 net tons as against 2,212,000 net tons during the week previous and 1,872,000 net tons during the week of July 20, 1917.

Shipments during the week of July 20 decreased slightly from all districts with exception of Iowa, Texas and the Southwest States, the increase in this district amounting to 1.2 per cent. over the week of July 13. Carriers' reports show that shipments from Central Pennsylvania decreased 2.4 per cent., from Ohio 1.5 per cent., from Southwest Virginia 5.6 per cent. and from Illinois, Indiana and Western Kentucky 2.3 per cent.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: June 29	July 6	July 13	July 20
Bituminous shipments, 123 roads.	219,625	180,090	235,291*	229,545†
Anthracite shipments, 9 roads...	41,641	31,493	42,419*	40,664†

* Revised from last report. † Subject to revision.

Anthracite shipments during the week ended July 20, declined 1755 carloads or 4.2 per cent. compared with the week preceding, the total movements amounting to 40,664 carloads.

Beehive Coke—The production of beehive coke in the United States during the week ended July 20 is estimated at 668,188 net tons as against 680,285 net tons during the week preceding, or a decrease of 1.8 per cent. The average production per working day during the week of the 20th is estimated at 111,000 net tons as compared with 113,000 net tons during the week preceding.

Byproduct Coke—Working conditions in the byproduct coke industry improved considerably during the week ended July 20. The plants of the country produced 517,671 net tons of coke and were operated at 91.2 per cent. of their present capacity as against 89.8 per cent. during the week of July 13. Repairs to plants during the week caused losses attributed thereto to decrease from 5.4 per cent. to 4.8 per cent. and other causes which entailed a loss of 1.9 per cent. of present capacity during the week of July 13 decreased to 1.1 per cent.

BUSINESS OPINIONS

Bradstreet's—The line of cleavage between war industries and what are termed non-essentials is more marked, the first named becoming more active, while the latter, feeling increased difficulty in getting adequate supplies of materials, labor and coal, faces a serious situation. The week has seen further large drafts made upon man power for the military service, a marked shifting of existing forces, and increased participation of women in industry being foreshadowed. Further heavy orders for and enlargements of munition plants, increased speed in steel production and in shipbuilding, and heavily augmented outputs of clothing and other supplies for the rapidly growing armies, are other features of the week.

American Wool and Cotton Reporter—The wool situation has settled down to a point where manufacturers can be relatively certain as to what their supply of raw material will be. It is quite likely to be the supply of raw material which they have on hand, plus whatever amount of substitutes their ability will permit them to handle. It is felt that as long as the price of wool is regulated, manufacturers will be safe; but should any condition develop whereby the costs of raw material advance, the manufacturers would be placed in a difficult position. In cotton goods it will require strict regulation, much more strict than has been noted up to the present, if a regular price scheme is to be established and if that stability which is so desirable is to be imparted to the market.

The Iron Age—In its third warning to consumers of steel within three months the War Industries Board puts the needs of the second half of the year for war and essential industries at 20,000,000 tons of finished steel products, or 3,500,000 tons more than the expected output. A sharp challenge of the 20,000,000-ton estimate came from automobile interests, accompanied by a call for a definite assurance as to steel supply, even on a reduced scale. No assurance has been given, nor can it be given, the most certain thing in the prospect being that the use of steel for war purposes will increase, while production is less likely to increase.

Marshall Field & Co.—Current wholesale distribution of dry goods is in excess of the large shipments of the corresponding week in 1917. Road sales are larger than those for the same period a year ago. Customers have been in to market in greater numbers. Collections are very satisfactory.

The Dry Goods Economist—Interest in textiles during the week has been devoted chiefly to the price-fixing of cottons, accomplished and prospective, the possibility of getting additional supplies of wool, and measures which will have to be adopted if it becomes necessary to depend entirely on existing stocks of dress goods and of other woolen fabrics for the trade's needs during the coming fall and winter. Emphasis was given to discussions of the cotton and woolen goods situation by the announcement of Secretary of War Baker as to the need for an army of 5,000,000 men before the end of this year. Secretary Baker supplemented this assertion with the statement that at least 2,000,000 men must be in Europe before Dec. 31.

Atlantic Seaboard

BOSTON

Receipts of bituminous now in good volume. Reserve stocks creeping up, especially with smaller users. Railroads accumulate stocks slowly, but are far behind last year's reserve. All-rail shipments continue to show steady increase, although figures are about the same as for March and April. No sign yet of car congestion on New England roads. Number of gas plants where usual source of supply is Pittsburgh or Connellsville, find no provision made in fuel "budget." Hampton Roads situation better, but detention is certain if fuel authorities sag off from recent orders turning coal to Tidewater. Anthracite receipts are fair all-rail but still slow by water. Agitation over municipal buying.

Bituminous—Ample car-supply, record production, and perceptible increases in stocks on hand have all had their favorable effect on New England buyers. Distinctly there is a much better feeling in the trade over the status of bituminous than was the case a month ago. It has even had its effect upon the purchase of anthracite screenings. There is simply a less anxious disposition among buyers who for nearly two years now have been under constant strain to get coal forward. This is probably as near as we shall come to what in normal years would be midsummer dullness.

Larger stocks are especially noted among the smaller steam-users. The shortage of labor everywhere is a factor and distributors are careful about sending cars in large number to certain plants because of the delays that usually follow. The large consumers are not well stocked in proportion. In fact, some of the largest utilities have been unable thus far to accumulate coal in sufficient volume to give them even a safe margin of supply. The corps of scouts organized by the New England Wholesale Coal Association is doing effective work. There is a natural tendency of consumers to exaggerate the tonnage used and for that reason the use of experienced coal men in policing distribution is of special value.

Effective July 22 all wagon-loaded coal in box cars in the central Pennsylvania districts was taken over by the Fuel Administration, the coal to be sent to the scales for disposition by the district representative. It is assumed that this will mean a considerably increased movement to this territory. Wagon coal forwarded on direct requisition through the Fuel Administration is to be invoiced to Mr. Storrow when tagged for New England points. New England consumers are ready to take whatever tonnage can come forward in box cars and the effort is made to spread them over a wide area in order to prevent detention at destination.

As yet there are no indications of congestion at any of the New England gateways The roads at this end are handling promptly all the coal traffic turned over to them and so long as general freight remains at its present level at least 200 cars more per day could be taken care of. A week ago there was some anxiety lest the New Haven R. R. show signs of extra detention at certain stations but it was recognized that these local situations were due to scarcity of help rather than to lack of motive power. The worry therefore was over possible delay in returning empties and a temporary car shortage that might follow. Part of the car accumulation was due to wholesale diversions of coal originally marked for South Amboy and since this was done in blocks of 400 to 500 cars there were bound to be humps here and there.

Notwithstanding all the representations that have been made to Washington over the heavy tonnage of railroad fuel being drawn from gas coal districts, particularly from grades low in ash and sulphur, railroad contracts are receiving 90 @ 100 per cent. performance, while illuminating gas requirements in New England are in arrears on shipments. It has been pointed out repeatedly that the use of high grade gas coal in locomotives is wasteful and that the railroads might as well begin now to use medium grades on fast trains.

The outlook for illuminating plants gets complicated when usual sources of supply are absolutely shut off and the gas plants are obliged to look for consideration at the hands of new shippers in districts that are already overburdened with other requisitions. For the moment an increased tonnage of Kanawha splint and other West Virginia high volatiles is being received via Hampton Roads, but it is hard to see how an adequate tonnage can be relied upon. Lately there has even been a tendency to arrange for gas coal in the Kentucky districts, sample shipments having been forwarded by rail, but doubtless there will be a regulation to prevent cars being used for so long a haul.

The volume of coal eastbound to Hampton Roads continues large and despatch at the piers has correspondingly improved. At this writing there are only about 30 bottoms waiting where a fortnight ago there were 70, and daily dumpings are being held at the 60,000 ton mark. Coastwise steamers have suffered some detention but the demurrage paid was not so serious as feared, two days at 25c. per ton having been the average for both loading and discharging. Renewal of U-boat activities off the coast has again caused slower movement. One of the results is a general order through the Emergency Fleet Corporation to camouflage steamers in the coal trade. The number of ships in repair yards is away above normal, although at this juncture with the number of new vessels entering the service a little extra time spent on camouflage will not be any great handicap.

Anthracite—For 25 days in July the daily receipts of domestic sizes at the five gateways averaged 644 cars. The daily average for steam sizes was 180 cars or 23 per cent. of the total anthracite. The latter is smaller in percentage than heretofore but this is due to increased movement of domestic sizes. While these figures indicate fair shipments all-rail, the mark is considerably below what was reached in June. August will therefore have to show a material increase if New England is to receive its full quota. Water shipments are still seriously affected by the lack of towing power and the cautious operations of what barges and tugs remain in service. Receipts from New York ports are also affected by the disinclination of Long Island Sound barge owners to send their craft this side of the Cape because of the delay in moving bottoms from the canal to Boston points.

The desire of Boston municipal authorities to take over the retail distribution of anthracite has had a prominent place in the newspapers the past week. Mostly this publicity disclosed a lack of information on what seems to be a peculiarly difficult business to understand. The mere advance of 25 per cent. in railroad tolls effective Jun. 25 seems to have meant nothing at all to the city fathers and they showed great surprise and even resentment over an advance in retail prices to cover the extra cost.

NEW YORK

Anthracite moving easier but supplies are lacking. New state fuel administrator pleases the trade. Dumpings at the local tidewater piers fall off. Anthracite committee discontinues shipments to various communities. Bituminous conditions improve. Car supply better and railroads move coal rapidly. Change made in bunker pools. Labor shows dissatisfaction.

Anthracite—There has been a noticeable change in the situation. Coal is moving easier, but there is no more surplus on hand owing to the continued heavy demand.

The trade here feels easier now that the office of state fuel administrator has been filled by the appointment of D. W. Cooke, who has been identified with the Erie R. R. as vice president in charge of traffic, and who is thoroughly acquainted with the coal industry. It is expected that Mr. Cooke will see to it that New York will receive its just quota of fuel and that its receipt will soon wipe out the feeling that New York will face a famine next winter. Mr. Cooke promptly entered into the solving of the problems before him and has already had conferences with some of the county administrators of the state. Following Mr. Cooke's appointment there was a strong rumor that C. E. Robertson, who was deputy administrator under Albert H. Wiggin, and since the latter's resignation acted as state administrator, had sent his resignation to Dr. Garfield. When it was announced that it was the intention of the Washington authorities to name two administrators for New York State it was stated that Mr. Robertson was slated to look after New York City and Long Island, which was to comprise one district. Mr. Robertson was not in favor of dividing the state, and the division has not been made.

Although production reports indicate that the mines are operating at capacity with existing labor conditions, the local situation is described as being as bad as at any time. Domestic coals are not to be had in greater quantities than have existed for some time and this includes pea and buckwheat No. 1. Consumers in some instances are using rice in place of buckwheat and some have resorted to burning barley in place of the larger of the steam sizes.

In view of the optimistic reports from the mining regions as to production, the trade here is inquiring as to the destination of the shipments. No gain is reported in receipts here and the dumpings at the local tidewater docks for the week ended July 26 show a falling off of 321 cars, as compared with the week previous, when 7375 cars were discharged. For the week ended July 26 7054 cars were dumped. If reports are authentic this market is to be accorded increased shipments beginning early in August.

There is plenty of barley to be had and most dealers say they have more of this size on hand than they have had in many months. Many of them are looking for bituminous so that they can dispose of both coals together.

Conditions in the mining fields are unchanged. Labor continues to leave the mines for other industries where higher wages prevail, but the authorities have taken steps to prevent this and to put mine workers in deferred classes. In this way it is hoped to keep production up to the top notch. The mine workers are watching with interest the efforts of their leaders to reopen the wage agreement and appear to be confident that they will receive increased wages. They are being urged by their leaders to do everything possible to keep up a record production, meetings being held in the three districts for that purpose.

The anthracite committee of the fuel administration has issued orders discontinuing shipments of domestic coals, including pea, into 51 communities in Vermont and to 89 counties in Illinois. The committee also placed an embargo on all shipments of pea and larger to all points in Ohio south of the main line of the Erie R. R. running across the state from Orange to Wren.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports, are as follows:

	Circular	Individual		Circular	Individua
Broken	$6.75	$7.50	Pea	$5.20	$5.95
Egg	6.35	7.10	Buck	5.10	5.90
Stove	6.60	7.35	Rice	4.65	5.10
Chestnut	6.70	7.45	Barley	4.15	4.30
			Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—With conditions indicating a slight improvement there is a feeling that with the mines keeping up to their production of the past two weeks the expected shortage of bituminous next winter might be averted. The heavy demands do not, however, permit of much storing in this vicinity. Reports from other near-by sections indicate that manufacturers are more fortunate and that some of them have good sized storage piles.

Further changes have been announced by the Tidewater Coal Exchange in the composition of the pools containing coals suitable for bunkering of transatlantic steamers. All coals consigned to Pool No. 9, when intended for use in bunkers, are to be sent to Pool No. 71, a new pool, and the coals formerly consigned to Pool No. 10 that have been allowed to be used for bunkering for transatlantic steamers are to be sent to Pool No. 72, also a new pool. All other coals sent to Pool No. 9 are to be used for commercial purposes. No coals are to be mixed, that is, coals sent to Pools Nos. 71 and 72 cannot be loaded into the same cargo. Under the new orders coals consigned to Pools Nos. 1, 71 and 72 can be used for transatlantic bunkers, while those sent to Pools Nos. 1, 4, 10, 71 and 72 are permissible for coastwise bunkers.

It is expected that these changes in bunkering coals will increase the quantity of commercial coals in this market. Consumers are said to be willing to pay the additional cost allowed producers of bunker coals if they could obtain some of them for commercial purposes, so urgent is the demand for fuel.

There is a better feeling among operators as to the outlook. Car supply on the Pennsylvania and New York Central is said to be all that can be expected at this time, but labor is dissatisfied. The railroads are doing much better in the movement of coal. Shipments from central Pennsylvania to New Jersey points are coming through in four days, whereas the average at the corresponding time last year was from 3 to 5 days longer.

The demand for railroad fuel has increased rapidly and some of the roads that heretofore have used anthracite on their passenger locomotives are now using a

mixture of bituminous and anthracite steam sizes.

The public has been warned that violators of the new "lightless" night rules will be prosecuted.

There was a falling off in dumpings at the local tidewater docks for the seven days July 20 to 26, inclusive, 6922 cars having been dumped, as against 7130 the previous week.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5 c. higher.

PHILADELPHIA

Anthracite demand continues despite hot weather. Slight improvement in receipts. Dealers doubtful as to future; authorities optimistic. Miners' unrest affects trade. State tax refund. Additional carrying charge. Little canal tonnage now expected. Exports supervised. Lightless nights in effect. Bituminous continues in good volume. Car supply in excess of needs at times. Government ownership doubted.

Anthracite—Despite a week of intensely hot weather there was no diminution in the demand of the public for coal. As many people feel summer is slipping away without coal in their cellars their anxiety increases. Of course the most of these are people who never heretofore ordered their coal in the summer, but now that they have been induced to do so they fear if the coal is not delivered before Sept. 1 they are liable to suffer accordingly. As to receipts there is just the barest possibility that on the average shipments have been slightly better than the previous week, but even at that not up to the quota for the city.

It is generally known among the dealers that there is a slight decrease in production of domestic sizes at the mines from week to week as compared with last year and they are probably more pessimistic than the consumers. However, we feel that the fuel authorities have begun to give this fact the fullest recognition now, as the instructions to cut off shipments to certain states contiguous to soft coal mines increase.

The unrest among the miners is being felt among the interests here, from producer to consumer. The operators here seem more anxious to increase production than anything else and now have a plan whereby the patriotism of the men can be further stirred to increased activity in coal production. The plan is to engage soldiers who have served in foreign armies, such as Poles, Slavs and Italians to go into the region and urge upon the men the importance of their staying in the mines and producing coal and that by so doing they will be doing a work equal to the soldier in the field. This plan has gained much impetus since the men are refusing exemption by the draft boards and getting into the war by enlisting.

To the surprise of every one in the trade one of the large companies has sent notices to its customers asking them to make up bills for tax collected under the last state tax law, which was declared invalid by the courts over a year ago. The dealers all along have known that they were entitled to this tax, but had come to the conclusion that the companies were too busy to work up the refund under present conditions. Since the lead has been taken it is quite likely now that all the other companies will follow.

Due to the many complaints entered by dealers because of the low charge allowed for carrying coal into cellars when it cannot be chuted in, the administration has granted an increase of 25c. to 40c. a ton. This is hardly satisfactory, however, and a number of dealers are reported as refusing to take orders where there is an extra carry. Some of the dealers had adopted the practice of dumping the coal on the sidewalk, but the fuel authorities refused to place their official sanction on this. Some consumers are making arrangements to do their own carrying. The fuel authorities have also had complaints from citizens who claim that dealers will not take their orders at all, claiming they have already more orders than they can take care of.

With the summer almost half gone it is seen that little coal will reach the city via canals, although great promises had been held out earlier in the summer. The matter has not been abandoned by any means, for dredging of the Schuylkill canal continues and it is expected that some shipments will be made via that route. The Lehigh canal is in operation, but whereas 40 crews were operating last year, only 26 are working this summer and no shipments are made south of Bristol, Penn. Dealers here with water yards are being supplied via barges from Port Richmond piers.

The lightless night order has gone into effect without friction, although in some sections a few violations were discovered, probably due to a misunderstanding of the edict. It is believed that a considerable saving of coal will be effected by this curtailment of four nights of the week beginning with Monday.

The steam trade continues as active as in midwinter. No coal of any size, except culm, is offered, and this is so well taken by outside markets that little effort is being made to seek local business. It is also understood that shipments of this coal have recommenced to the states which had been cut off by the order prohibiting shipments of any kind of anthracite. The authorities were shown that shipments of culm to these states could not affect the general situation and thus authorized the resumption of culm sales.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—Good shipments of bituminous continue to arrive and it is the feeling that this condition will prevail right along now, at least until winter. The matter of car supply seems to have been solved and it is not uncommon these days for many mines to receive more cars than can be loaded. This is explained by the fact that when calls for cars are placed by mines they ask for the full rating of their plants, but there is no way of telling how many men will turn out on the succeeding day. This is a condition that is becoming general in the bituminous region and led to a report being issued from Washington stating that the mines as a whole have recently received more cars than they can use. The cars could be used if the men were available to produce the coal.

Quite a little trouble has been occasioned for the bituminous distribution committee by the shutting off of anthracite to 31 counties in the state. Retail dealers in those counties are calling upon this committee to procure them a source of supply of bituminous coal to take the place of the former anthracite. Before directing shipments it is necessary for the committee to have some assurance as to the credit standing of the applicants, many of whom only need a few cars of coal, and it is taking considerable time and effort to effect this.

Little credence is given locally to the intimation in some quarters that the Government is liable to assume control of the mines this winter if there should be a failure to produce sufficient coal to meet the needs of the country. As a matter of fact it is hard to be seen how the Government could have a closer control on the business than it has now.

BALTIMORE

This section hard hit by plan to send all available fuel to more distant points. Small reserves being rapidly exhausted. Hard coal, after brief spurt, continues record much behind expected schedule of receipts here.

Bituminous—Under the general Government plan of sending all coal possible to the Northwest and to New England in this mid-summer period, the Baltimore fuel district is hard hit. A. W. Calloway, Federal fuel director, who was in this city during the week, explained that it had been decided to cut to a minimum the deliveries in territories contiguous to mining sections in order that distant consuming territories, where sufficient fuel is absolutely necessary for war industries, be supplied before any chance of wintry weather cutoff comes. This would seem to mean that consumers here of soft coal may have to scrape along from hand to mouth until near Thanksgiving and rely throughout the winter upon heavier deliveries to keep them going at a time when deliveries farther north would be difficult if not impossible. The office of Maryland Fuel Administrator Meyer was the scene of much urging for fuel the past week, and this condition continues, despite the fact that many consumers have not awakened to the tightness of the situation. It is only those who have been caught without coal by the cutting off or curtailment of their direct deliveries, or those who are now forced to use part of reserve supplies at a time when they are usually stocking up, who make up the group of more urgent claimants.

Anthracite—Hard coal men here report another slump in receipts after a brief spurt in the first ten-day period of July. The general condition is shown by the fact that the total receipts for June fell not only behind the 10 per cent. increase in allotment set for Maryland, but behind the receipts for June of 1917. Last month the total received was 58,777 tons, against 64,751 tons in June, 1917. In addition war industries here used probably 4500 tons more this June of hard coal than in June of last year. On July 1 the total reserve of hard coal in Baltimore, as reported by dealers, was 23,000 tons; and the same dealers reported 264,000 tons of orders undelivered on their books, with prospects of a total of 300,000 tons undelivered before Aug. 1. At the rate of present receipts it would take until the end of January to deliver the coal already ordered. Each new draft is leaving the retail dealers with less working force, and even if the coal should come in heavily in September and October the majority of hard-coal men here fail to figure out how they can deliver it.

Lake Markets

PITTSBURGH

Heavy Lake shipments. Production substantially at record rate. Much coal by river and truck.

At latest reports Lake shipments from the Pittsburgh district were running at the rate of 1,400,000 tons for the month, but the month as a whole is expected to make a better showing than this. The original quota for the month was 1,300,000 tons, but on account of the extra demands upon West Virginia and Kentucky from the navy the Pittsburgh district has been required to exceed its quota as much as possible.

Production of coal in the district is substantially at record rate. Car supplies are not equal to requirements, but are more satisfactory than at any time recently. Labor performance has improved somewhat and the efforts of the various Governmental agencies are being continued to produce as nearly 100 per cent. efficiency as possible.

Nearby consumers of coal are receiving substantially as much fuel as required for current operations. No rail coal is being stocked, as the local distributor's orders are emphatic on that point. River coal shipments are heavy and a considerable proportion of this coal is being stocked, by the limited number of consumers who can take river delivery. A project has just been broached to lengthen the locks on the Monongahela river, as with the increasing traffic there is hardly enough capacity, while time is lost breaking tows. A great deal of coal continues to be trucked to manufacturing plants. Buyers of such fuel are making the best of a bad bargain, as the cost of the coal is materially increased.

The market remains quotable at the set limits: Slack, $2.10; mine run, $2.35; screened, $2.60 per net ton at mine, Pittsburgh district, brokers being allowed to charge customers up to 15c. commission in addition.

BUFFALO

Large demand for anthracite. Better shipments by lake. Bituminous moving slowly. Jobbers not hopeful, but will keep up business as best they can.

Bituminous—The trade does not change much. A ray of hope is found in the official report of record production, but a jobber who claims to be posted says that it cannot last. He also takes the pessimistic side of the case by predicting a political outcome of the public control of the trade. This section has about forgotten politics in such matters. It is well to look on the other side of business these days. As a rule this is done. If a jobber can get no coal he watches his chance and tries again. Many reports of the alleged actions of the Government with regard to the jobber are going about, but they almost always turn out to be conjectures.

Bituminous prices are as follows to this market: Thin-vein Allegheny Valley, all sizes, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; cannel, $6.20; smithing, $5.85, all per net ton, f.o.b. Buffalo, with jobber's profit added.

Anthracite—The situation is hard to define, for while the supply is next to noth-

ing, the demand is heavy and insistent. Retailers send their wagons to the trestles on days when coal is to be had, but often not more than half the long line gets any coal. Then the customer blames the dealers because the orders are not filled. At the same time the cellars must contain more coal than in any summer during previous years. The county fuel administrator has asked for 900,000 tons of anthracite, but so far is only promised a minimum that shall run above 700,000 tons, which is only a little more than has been distributed in former winters.

The fuel administrator on July 24 fixed the city prices of coal at the curb at $9.30 for grate, $8.95 for egg, $9.20 for stove, $9.25 for chestnut, $7.80 for pea and $7.75 for buckwheat. This is $1.85 per ton more than the wholesale price. Retailers in ordinary times always contended that they ought to get a margin of $1.50, but competition often cut it down to 85 cents.

Lake shipments of anthracite are increasing again, being for the week 114,700 net tons, of which 53,500 tons cleared for Duluth and Superior, 30,200 tons for Chicago, 14,900 tons for Milwaukee, 7500 tons for Waukegan, 7000 tons for Fort William, 1000 tons for Depere and 600 tons for Mackinaw.

CLEVELAND

Local bituminous coal requirements have been made subsidiary to the pressing demand for supplies for the Northwest. Industrial stocking of bituminous has been ended until after Oct. 1. Industrial concerns well stocked are to be denied further shipments and will be compelled to dig into their stockpiles.

Bituminous—Above all developments in both the local bituminous and the Lake trade are the general orders of the United States Fuel Administration giving the right-of-way to shipments for the Northwest. It is hoped that Lake shipments may be brought up to schedule by Oct. 1, and consequently, every ton of coal possible must be rushed up the Lakes. Industrial plants that have from four to six months' supply on hand must not expect further supplies at present. Industrial stocking will be cut to a minimum.

Bituminous coal has proved more and more difficult for retail dealers in Cleveland and northern Ohio to obtain the past few days, and most dealers are considerably behind on orders. It is stated that less than one-fourth of the domestic requirements for bituminous for this winter have been satisfied to date. Car supply in the southern Ohio fields continues 100 per cent. or close to that figure. The labor situation has not improved, but the inauguration of the new Federal plan for recruiting labor Aug. 1 will help some, operators believe.

Anthracite—Virtually no anthracite is reported entering the Cleveland and northern Ohio market, but dealers are expecting further supplies for domestic consumers before cold weather sets in.

Lake Trade—Bituminous for the Northwest in the early part of the week was coming forward at the rate of 1,000,000 tons a week, but shipments in the latter part of the week have brought the estimate to a lower level. Revised figures for the week ending July 20 now place the shipments to the Northwest at 913,672 tons. First figures for the week ended July 27 place shipments at 978,800 tons. As has been the case all season, capacity is far in excess of cargoes.

DETROIT

Improvement in supply of domestic coal fails to develop. Household distribution is delayed. Lake shipments show gain.

Bituminous—For the present interest of local jobbers and retail dealers is held by the small volume of coal available for domestic use that is being received in Detroit. While the bituminous shipments arriving are lighter than in previous years, the supply of steam coal seems to be sufficient to meet present needs of the consumers, though not much opportunity is given for adding to reserves.

As regards consumers of domestic coal, the situation is less satisfactory. The stock coming in is largely mine run and not adapted for use in the ordinary household heating plant, while there is a marked scarcity of domestic lump and sizes favored by domestic users. This condition is made more vexatious by the fact that under regulations of the state fuel administrator a largely increased use of bituminous coal is made necessary as a substitute for anthracite, coke and smokeless coal.

Anthracite—Incoming shipments of anthracite are small, some days amounting to fewer than 30 cars and seldom exceeding 40 cars. The dilatory method of supplying the needs of Detroit consumers while shipments of large volume are being sent elsewhere is preventing distribution among consumers at a time when it should be well under way. The Detroit Board of Commerce has decided to intervene in the interest of residents of Detroit and Michigan.

Headed by President J. J. Crowley, a committee of 15 prominent Detroiters left Sunday to appeal to the Federal Fuel Administrator to expedite movement of coal into Detroit and to urge also that the state's allotment of 1,201,000 tons of anthracite be increased to an amount more nearly commensurate with requirements and to a degree that in part at least will offset the loss of some 600,000 tons of coke and smokeless coal diverted from Detroit for war purposes.

Lake Trade—Coal has been moving rather freely to lake loading docks during the week and it is estimated by shippers that nearly 1,000,000 tons of cargo coal were loaded last week. Vessel supply offered for loading exceeds the available cargoes and a heavier movement will be necessary to meet the schedule of shipments for the month.

COLUMBUS, OHIO

A steadier car supply is helping production in all Ohio fields. Strong demand for all sizes is still reported from every quarter. The Lake trade is especially active.

Production figures continue to rise in all mining districts because of a better car supply and steadier employment. There is still a labor shortage but that is to be expected under the circumstances. On the whole the market is in good shape as the demand for all grades and sizes remains strong. Prospects indicate a continuation of the strong demand for domestic, steam and Lake tonnage.

The Lake business is being rushed as fast as possible as producers and shippers wish to forestall a possible priority order later in the season. The vessel movement is active, although some boats are still going to the head of the Lakes light, because of lack of coal tonnage at the Lower Lake ports. The ore trade is rushing and the Federal authorities are making every effort to get the ore to the manufacturing sections. The shortage at the head of the Lakes is still a matter of deep concern as it is feared that the Lake trade can not be pushed much stronger than at present.

CINCINNATI

Improved car supply and beginning of river shipments have helped receipts. Volume of movement is satisfactory and demand heavy.

The receipt in Cincinnati of a large shipment of river coal which was sent down by an artificial wave, added materially to the total volume of fuel available. The first of a series of such shipments, this transportation medium will undoubtedly be an important factor during the remainder of the summer. Better car conditions at many mines were also reported last week, enabling operators to forward more coal. The movement through this gateway for the Lake ports and other Northern destinations was correspondingly heavier. Local receipts are satisfactory, although the wants of dealers and consumers in this immediate section have to give way, to a large extent, to the requirements of those more distant from the mines, in accordance with the policy of the Government in the distribution of fuel. The demand for storage continues to be heavy and insistent, especially from domestic consumers, who in many cases are worried over their winter's coal supply. The trade is confident that the needs of the public, both for industrial and domestic purposes, will be met next winter more thoroughly and generally than last winter, both on account of improved production and distribution and on account of the fact that everybody has been educated to the necessity of taking coal when it is available, thus freeing the distributing machinery for essential work later on.

LOUISVILLE, KY.

Demand continues strong for all grades of coal, with slack in somewhat lighter call due to the placing of nut and slack on the same relative basis.

Coal production in the western Kentucky field has suffered during the past two or three weeks due to heavy draft calls on colored laborers. In eastern Kentucky white labor is used principally, and the recent calls haven't affected such labor so greatly.

At the present time the mines are getting a good supply of cars, and a good movement of coal and coke is being noted considering the short supplies of labor obtainable.

In a retail way the situation shows little change. The local dealers are far behind on orders, and coal is scarce, with few yards with any supply on hand, and being forced to make deliveries directly from cars as rapidly as the coal can be secured. Orders now on hand will keep the trade busy for more than two weeks. About the only coal to be had at this time is western Kentucky and a little Hazard coal, eastern Kentucky grades being practically unobtainable.

BIRMINGHAM

Production showing a slow but steady gain. Market conditions good as regards demand, inquiries being strong for domestic, while steam appears to be a little easier than last week. Car shortage reported in a few instances, but so far this has not crippled production.

A general improvement is noted in the output of coal in the Alabama field during the past week or so and the production is expected to show a steady gain from now on. The slackers are receiving requests from the Fuel Administration to work full time, and the forces at the mines are being increased by the addition of men from other less essential industries.

Local conditions as regards the demand and supply show little or no change over last week, reports from some distribution sources indicating a slightly easier steam market, though inquiries are still strong and much in excess of the supply.

Domestic trade, both wholesale and retail, is active, and there is a pressing demand on the mines for every ton that can be produced. Everybody appears to be anxious to lay in coal at once, hence such abnormal immediate requirements cannot be met. Coal is being stored at a satisfactory rate, though retailers are not receiving the desired tonnage to meet orders in hand.

Slight interruptions to operations have been experienced by mines on the Southern and Frisco recently by the lack of equipment for loading. However, there has been no serious delay on this account so far and the loss in production has been immaterial.

Coke

CONNELLSVILLE

Market offerings negligible despite increased production. Still more byproduct coke.

While the production of Connellsville coke has been increasing slightly of late there is still little offered in the open market, except of foundry grade. Furnacemen think it can hardly be long until there are relatively free offerings in the market, and if such a condition obtains there is a possibility of prices being affected, for there is admittedly quite a handsome profit in coke making at the Government prices, much more than there is in the production of coal. It is well recognized in the trade, from all past experiences, that when there is a slight shortage of coke it is extremely easy to sell while when it is a bit plentiful it is difficult to sell.

While the production of Connellsville coke has increased but slightly of late, the mere fact that any increase at all has occurred is quite encouraging, considering that in the past two months the 180 new byproduct ovens of the American Steel & Wire Co., at Cleveland, have been put in operation, and 128 ovens of the Carnegie plant at Clairton. The Connellsville region has to ship correspondingly more coal and for it to maintain and even increase its coke output is doing well. Another case of more byproduct coke is the 60-oven addition to the Bethlehem Steel Co.'s 120 ovens at Steelton, put in operation July 9, increasing the output at Steelton by fully 20,000 tons a month. The next byproduct plant will be the National Tube Co.'s 208 ovens at Lorain, some of the ovens now being in process of drying out, and full output from the plant is expected by September.

The market remains quotable at the set limits for furnace and foundry coke, $6 and $7 respectively, per net ton at ovens. Limits on other descriptions are: Crushed, over 3-in., $7.30; crushed, under 3-in., $5; breeze, $3.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended July 20 at 351,650 tons, a decrease of 1720 tons.

Buffalo—The demand is heavy, both for commercial sizes and domestic small stuff. The furnaces obtain supplies from the producers with difficulty, but manage to keep running. Consumers of breeze and gas

coke get a small amount. The Fuel Administration allows $4.54 for breeze at the place of production, but some shippers still sell it at the old price of $2.45 at the ovens. The receipts of iron ore by Lake keep up well, the amount for the week being 322,232 gross tons.

Middle Western

GENERAL REVIEW

Rumor that jobber's 15c. margin is to be abolished, and another to effect that Government is to take over several Middle West mines.

The most noticeable feature of the coal market for the past week was a large number of rumors, all of which, for the present at least, are without official confirmation or sanction. The most important of these rumors is to the effect that the United States Fuel Administration is contemplating a ruling which will abolish the 15c. per ton margin charged by a jobber for his purchasing agents' commission. If this rumor becomes a rule, it will mean that if the jobber is to continue in business it will be necessary for him to purchase his coal from the operator on a basis of at least 15c. per ton under the current Government price. As the average operator today can sell his entire output without the slightest bit of trouble, the outlook for the jobber is pretty black. We understand that there is enough foundation to this rumor to have caused a committee from the National Coal Jobbers' Association to hurry to Washington to take the matter up with the proper parties.

Another rumor which has gained considerable credence is that the Government will shortly take over a number of the larger coal-producing properties in this territory. It appears that some of the operators are not taking the care they should of the orders given them by the various Fuel Administration representatives, and for this reason, to enforce a compliance of its orders, the Fuel Administration is planning to step in, which will result in Government supervision and control of the mines in question. It is said that the problem will be handled in a manner similar to the Federal management of the railroads.

The last and least important of these current rumors is that there will be modification in Zone C which will bar shipments of Illinois coal from moving to certain districts of Iowa, which at the present time are in the Illinois zone.

CHICAGO

Market has eased up. Labor situation at mines much improved. High grade domestic coals firm. Steam trade stocking up. Some coals selling below Government price.

There has been a decided easing up of the market during the past few days. This is all the more remarkable in view of the fact that the Government about a week ago placed orders aggregating between two hundred thousand and three hundred thousand tons to be used at the various Government training camps, munitions factories, etc., throughout the Middle West. The only explanation for the present easing up of the market in the face of this large order is that the mines had an unusually good production week. The labor situation was perhaps a little better, as men are moving to the mines, anticipating the "Work or Fight" order, and the car supply all over the territory was extremely good.

High-grade domestic coals are of course firm, but this position has been weakened some by unusually large receipts of Lake coal. The steam trade is purchasing coal freely and stocking up what coal they do not use for their current needs, as a sort of insurance pile for the winter months. All the better grade coals from most of the producing districts are selling on a basis of Government price current at time of shipment, but there are some coals that are selling considerably below the price set by the Government.

Quotations in the Chicago market are as follows, per net ton, f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La-Salle, Bureau and Will.

MILWAUKEE

Increasing receipts of anthracite by Lake. Small dealers embarrassed by short allotment. No schedule of prices fixed. Conservation notes.

Anthracite has been coming in freely of late. Since last week's report five cargoes, aggregating 34,300 tons, have been put upon the docks. This makes a total of 209,891 tons of anthracite since the opening of navigation. The dock companies are not giving retailers a sufficient supply, however, and many small dealers are unable to supply their customers promptly. Some refuse to book any more orders until this situation changes. If present conditions should continue for any length of time, the smaller or "desk-room" middlemen are bound to be eliminated.

Stocks of bituminous coal were increased to the extent of 92,239 tons by cargo arrivals during the week, making the total since the opening of navigation 1,200,746 tons.

The anthracite schedule has not been announced as yet, and all coal deliveries made thus far remain unbilled. The state fuel administrator and fuel board continue to wrestle with the problem of fixing the margin of profit to dealers. The former maximum of $2.25 per ton has been pronounced too high.

The breweries of the city have been notified that they can use hydro-electric power in excess of the amount of coal they are permitted to consume. This rule does not apply to wood, however, even if such fuel is available without railway transportation. Illinois screenings are also forbidden in excess of the 50 per cent. fuel allotment.

A saving of 20 per cent. in the amount of fuel used by industries in Wisconsin is the purpose of Charles A. Cahill, state administrative engineer. The Milwaukee Street Railway Co. promises a saving of 10,000 tons of coal annually if it is allowed to inaugurate a skip-stop system. The matter is under consideration by the city authorities.

Two lightless nights per week are now the order in Milwaukee—Mondays and Tuesdays.

Fire is consuming 300 tons of bituminous coal in the bunkers of the lighting and heating plant of the University of Wisconsin at Madison. The bunkers are so situated that poisonous gases defeat every attempt to attack the burning mass.

The Dane County, Wis., fuel administrator has cut deliveries of coal in Madison from two-thirds to one-half, where the total amount exceeds six tons.

ST. LOUIS

The market shows a tendency to stiffen on Standard grades. The demand, however, is quiet both locally and in the country, and steam has been slow in moving. Car supply extremely poor and the distribution poorly managed. Transportation shows improvement. Large tonnage to move to Michigan.

The local situation has toned up somewhat in the past week principally because the tonnage is not available. In addition to the car shortage there is something radically wrong with the method of distribution. Some mines work every day and others only two or three days a week, taking the men away from some good operations to work at others that are supplied with the cars. Inquiries as to how this occurs bring no results and several operators are threatening to take the case to Washington and show up the inability to follow or the utter disregard for car distribution rules.

Screenings, which have been heavy, are picking up in a way on account of the coming shortage.

During the past week it has been agreed between the fuel administrator for Missouri, Wallace Crossley, and F. C. Honald, district representative of Chicago, who is in charge of the distribution of Illinois coal, that all the surplus in the Standard field on the lines of the Wabash, B. & O., Vandalia, L. & N. and Southern can move to Michigan, as prescribed by Mr. Honald, for a period of 60 days. This is going to bring about a tightening up of the local market and also convince local buyers that conditions are somewhat acute in other places if not at home.

The domestic call for Standard coal is not as good as might be expected. The labor problem is still a serious one in this field, but this is principally at mines where the car distribution has not been evenly pro-rated.

In the Mt. Olive field normal conditions continue to exist, with a car supply that is fairly good, a labor problem that is not bad, and a tonnage produced about equal to the demand.

The railroads still continue to take coal in large quantities from the Carterville field where there is a scarcity of cars and where transportation is not as good as in the other regions.

The labor problem in this field is about stationary, inasmuch as the draft will not affect Illinois for the month of July, but with the coming of August there is a likelihood of several thousand miners being taken in the new draft.

Conditions in the Duquoin field are somewhat similar to those in the Carterville district, with the railroads still getting a good tonnage and the car supply being short.

There are no eastern coals of any kind coming in. A little Arkansas moved in the past week with an advance of $1.50 a ton tacked on it, in accordance with the recent agreement of the miners and fuel administration officials in Arkansas.

The demand is good locally for all kinds of high grade coal, and the local condition in so far as storage coal is concerned for domestic purposes is very satisfactory to the fuel administration.

The prevailing market is as follows, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....

No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

SEATTLE

Car supply now adequate, but labor shortage holds up production. Domestic consumers lag in placing orders for fuel and last winter's experiences likely to be repeated.

The car supply in the state, while not wholly satisfactory, is said by the operators to be nearly equal to demands, and coal is getting away from the mines as fast as it is being produced. The shortage of labor, however, is now quite a problem. Labor officials estimate that the western Washington mines alone are short about 400 men at the present time, with no indication that this want can be supplied. Coal operators throughout the state report that they are operating to capacity and yet are unable to meet the demand. This is not coming from the domestic or householder consumer, but from industrial plants and railroads. The householder is not heeding the many warnings to purchase coal early, with the result that last winter's experiences are likely to be repeated this year. Owing to the impairment of the hoisting equipment of the Wellington Coal Co. bunkers, Nanoose Wellington coal shipped from British Columbia to this city will have to be delivered to bunkers in West Seattle; and to cover the additional expense the Fuel Administrator has permitted a raise in price of 20c. per ton. As the Canadian Fuel Administration has allowed a raise in the price of coal at the mines of the Wellington Coal Co., the United States Coal Administration has also permitted a raise in the retail price here of 65c. per ton on lump and 25c. on nut and pea of the Wellington variety. In coal circles this action is believed to foreshadow an increase in other Canadian coals on the local markets.

CURRENT PRICES—MATERIALS & SUPPLIES

IRON AND STEEL

STEEL SHEET PILING—The following price is base per 100 lb. f.o.b. Pittsburgh, with a comparison of a month and a year ago:

Birmingham	35%	35%
Chicago	45%	40%
Cincinnati	40—10%	40%

RAWHIDE LACING—40—5% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.99
Asbestos for high-pressure steam	1.76
Duck and rubber for piston packing	1.10
Flax, regular	.99
Flax, waterproofed	1.21
Compressed asbestos sheet	1.10
Wire insertion asbestos sheet	1.30
Rubber sheet	.66
Rubber sheet, wire insertion	.99
Rubber sheet, duck insertion	.55
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.21
Asbestos wick, ½- and 1-lb. balls	.75

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20%
Galvanized cast steel rigging	List
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	5%

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅝-in., 8 ft.; ¾-in., 6; ⅞-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0.34	Birmingham	$0.38
New York	.36	Denver	.35½
Cincinnati	.33½	Kansas City	.34
Chicago	.34	Seattle	.34
St. Paul	.34	St. Louis	.34
San Francisco	.32	Los Angeles	.35

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING

Pipe Size	Standard List Per Lin. Ft.
1-in.	$0.27
2-in.	.36
6-in.	.80
4-in.	.60
3-in.	.45
8-in.	1.10
10-in.	1.30

5-lb. cans	.....	.....	15.25	15.50	16.00	15.50
1-lb. cans	.....	.....	.....	.....	17.00	.....

COMMON BRICK—The prices per 1000 in cargo or carload lots are as follows:

Cincinnati	$13–16.75	Birmingham	$13.75
St. Louis	12.00	Denver	8.50

WIRING SUPPLIES—New York prices for tape and solder are as follows:

Friction tape, ½ lb. rolls	38c. per lb.
Rubber tape, ½-lb. rolls	45c. per lb.
Wire solder, 50-lb. pools	46c. per lb.
Soldering paste, 2-oz. cans	$1.20 per doz.

PREPARED ROOFING—Standard grade rubbered surface, complete with nails and cement, costs per square as follows in New York, St. Louis, Chicago and San Francisco.

	1-Ply		2-Ply		3-Ply	
	C.l.	L. C.l.	C.l.	L.C.l.	C.l.	L.Cl.
No. 1 grade	$1.30	$1.55	$1.60	$1.75	$1.90	$2.05
No. 2 grade	1.15	1.30	1.45	1.60	1.75	1.90

Asbestos asphalt saturated felt (14 lb. per square) costs $5.35 per 100 lb.

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $1.95 per roll in carload lots and $2.20 for smaller quantities.

Shingles, red and green slate finish cost $5.25 per square in carloads, $5.50 in smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York or Chicago:

	Carload Lots	Less than Carload Lots
Tarfelt (14 lb. per square of 100 sq. ft.)	64	65
Tar pitch (in 400-lb. bbl.)	21	22
Asphalt pitch (in barre's)	37	42
Asphalt felt	72.50	77.50

HOLLOW TILE—The price per 1000 in carload lots f.o.b. mine is as follows:

	4 x 12 x 12	8 x 12 x 12
St. Louis	$74.00	$138.00
Chicago	79.00	137.00
Denver, per ton	None	None
Kansas City	75.00	140.00
St. Paul	56.00	110.00
Boston	80.00	150.00
Birmingham	72.00	135.00
Cincinnati	72.75	136.10
Pittsburgh	86.50	147.10

LUMBER—Price of yellow pine per M in carload lots:

	1-in. Rough 10 In. x 16 Ft.	2-In. T. and G. 10 In. x 16 Ft.	8 x 8 In. x 20 Ft.
St. Louis	.....	$40.00	$40.00
Birmingham	$33.00	33.00	28 50
Denver	40.00	42.00	42 50
Cincinnati	45.00	44.00	39 00

STEEL SHEETS—The following are the prices in cents per pound from jobbers' warehouse at the cities named:

	Pittsburgh, Mill, in Carloads	New York Current	New York One Month Ago	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
*No. 28 black	5.00	6.495	6.445	10.00	6.42	9.50	6.52	9.50
*No. 26 black	4.90	6.395	6.345	9.90	6.32	9.40	6.42	9.40
*Nos. 22 and 24 black	4.85	6.345	6.295	9.85	6.27	9.35	6.37	9.35
Nos. 18 and 20 black	4.80	6.295	6.245	9.80	6.22	9.30	6.32	9.30
No. 16 blue annealed	4.45	5.695	5.645	9.70	5.62	9.70	5.72	9.70
No. 14 blue annealed	4.35	5.595	5.545	9.60	5.52	9.60	5.62	9.60
No. 10 blue annealed	4.25	5.495	5.445	9.50	5.42	9.50	5.52	9.50
*No. 28 galvanized	6.25	7.745	7.695	13.00	7.67	11.00	7.77	11.00

* Carload lots.

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.27	New Orleans	$0.385
Buffalo	.17	New York	.245
Chicago	.27	Philadelphia	.23
Cincinnati	.23	St. Louis	.34
Cleveland	.17	St. Paul	.495
Denver	.99	Pacific Coast (all rail)	1.25
Kansas City	.59		

Note—Add 3% transportation tax.

COAL AGE

Volume 14 New York, August 8, 1918 Number 6

A Single Purpose

By Floyd W. Parsons

THERE is no place on the earth today for a nation made up of nerveless, undecided people. A German Kaiser proposes to be master of the Universe. He exalts himself as superior clay. He justifies the subjugation of weaker nations. He glorifies brutality, prays to a substitute God and makes a religion of war.

This Prince of Death gazes without compassion on a world he has drenched with the blood of countless fathers and sons. He has brought about more misery than was caused by all the tyrants of history combined. Millions of women pray to Heaven for relief from their sufferings, and ask that retribution be sent upon the Teuton beasts who masquerade in the forms of men.

The German people have listened for generations to vicious teachings which are now firmly embedded in their natures. They believe that a policy of sentiment is folly; that enthusiasm for humanity is idiocy; that might is the supreme right, and that a nation has the right to do what it has the power to do; that the present conflict must leave nothing for the vanquished but their eyes to weep with; that war is the most august and sacred of human activities, and that peace is but a means to new wars.

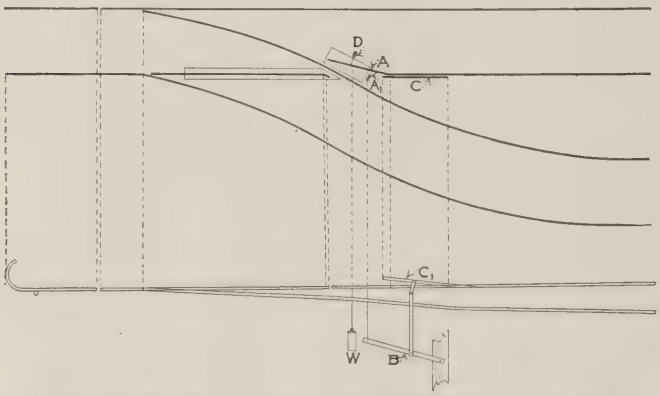
So long as the Hun believes in the virtue of such barbarous doctrines there can be no peace. How can any Christian nation hope to live in a world where a king and his people make slaves of their victims while alive and grind their bones into fertilizer to enrich the soil when dead. How can we expect to live happily on earth with men who say—"Kultur must build its cathedrals upon hills of corpses, seas of tears and the death rattle of the conquered. The lives of human beings are to be conserved only if it makes for the State's advancement."

OVER in France the very flower of American manhood is now shedding its blood. Many of our splendid sons already sleep in graves hastily dug in alien soil. Other Americans are fighting as men never fought before and youngsters with Hun bullets in their bodies try to slip away from the dressing stations and again join their comrades battling fiercely at the front.

While this is going on "over there" what are we doing here at home? Are we working every day, all day? Is every mining official on the job early and at his desk late? Does every miner at the working face say to himself with every four shovels of coal he loads into his car—"There's another 3-inch shell for the Hun"?

Over in Mercer County, Pennsylvania, 150 mine workers who had retired on account of old age went back to work again to help satisfy the urgent need for coal. They knew that every 8000-ton cargo ship that slid down the ways at a shipyard had used up 16,000 tons of coal in its construction. They had learned that every 42 cm. shell our boys fire at the Teutons meant a consumption of 900 pounds of coal, and they have donned their old mine clothes and gone into the fight as nobly as any youth who goes "over the top." What an example for those of us who are yet in our prime!

We are no longer only preparing for war, we are in it and there is no way out except the straight road to the finish. American miners can do more to stop the arrogant Hun than any other class of men on earth. No miner today is a patriot and deserves the friendship of honest, earnest Americans who slacks for a single hour when there are cars to load with coal.



We must win with our Allies now or fight alone later.

IDEAS AND SUGGESTIONS

Automatic Tipple Switch

BY T. F. PRICE
San Antonio, Texas

The accompanying illustration shows a handy arrangement that I designed and installed in the Hale No. 1 mine of the Madeira-Hill Coal Co. at Phillipsburg, Penn. The device was found to be quite efficient and cut down

PLAN AND ELEVATION OF AUTOMATIC SWITCH

the operating expense, since it did away with the services of two men in operating the tipple.

No dimensions are shown on the drawing, as these will vary with the diameter of the car wheel used and the arrangement of the tipple. When a device of this kind, however, is built for wheels 18 in. in diameter, it will successfully handle cars with 14-in. wheels if the other portions of the dump and kickback will also accommodate wheels of this size.

Referring to the illustration, the latch *A* normally stands open, being held in this position by the weight *W*. This latch is operated (closed) by the car pressing down the lever *C*, which depresses the arm *B* and actuates the latch through the medium of the cable A_1. The loaded car is now free to pass over the latch to the dump or kickback. After the passage of the car the latch is again opened by the weight *W*. This permits the free return of the car.

Chasing the Elusive "Bugs" Out of the Commutator

BY FRANK HUSKINSON
Lafayette, Colo.

In the rewinding or repairing of any direct-current type of armature, one of the most important details to attend to before putting any of the leads into the commutator is to test for and remove all short-circuits between the adjacent commutator bars. These are familiarly called "bugs," and in this respect they are rightly named. There has been many a time that the "electrician" was on the verge of "bugs" while chasing these elusive bugs out of the commutator.

An armature will come into the shop for repairs, and probably the top leads will be removed from the commutator and also a few of the bottom leads. Repairs are made and the commutator is given a test for "bugs," with the result that several are found that can not be located on the surface. It is thus necessary to remove the front ring, and sometimes the entire commutator will have to be removed from the armature shaft and taken apart just to clear up a few partially shorted bars or bugs.

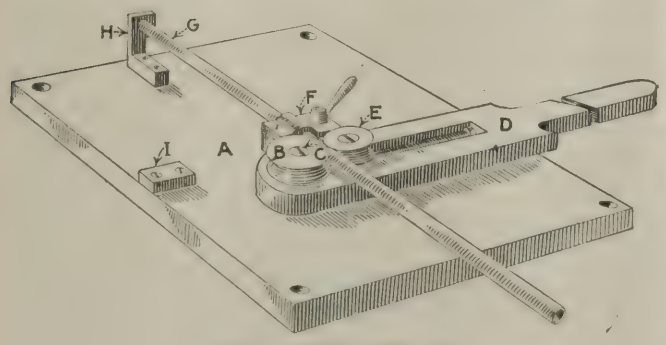
Now it is some job to remove a commutator from the armature shaft, take it apart and rebuild it again, all on account of a few bugs. A short-circuit of this kind is as a rule caused by the current leaking across the mica and carbonizing it to a certain degree. If this condition is not removed and the armature is put in service with a partial short or bug between the commutator bars, it results in the burning out of the coils connected to those particular bars. In some cases the resistance is so high at the point of short-circuit that the coil will withstand the effects of the bug for an indefinite period of time. Nevertheless the trouble is always there and is manifested by the short-circuited bars heating. The final results are the burning out of the coil or coils. Or again, it results in the mica rings carbonizing to such an extent that the current eats a path to the iron core, thereby causing a ground that puts the armature out of commission. It is therefore highly important that a commutator be given a thorough test and all "bugs" removed from it.

In my experiences with this class of trouble I have found several effective ways of removing a bug, or partial short-circuit, from between two commutator bars. In making tests I always use one or more lamps in series with my test terminals when the test terminals are placed on adjacent bars. If there is no bug there will be no light; on the other hand, if the bars are shorted the lamp will light up. The nature of the bug can generally be judged by the brightness and wavering of the light. If the trouble is on the visible parts of the commutator it is an easy matter to clear it. If it is in an inaccessible place, such as on the bottom part of the mica and bars, it can sometimes be located by watching the mica closely, as the arc caused by the current jumping across this insulation can be seen through the mica.

To remove such a bug without taking the commutator apart I have had considerable success by taking a small drill and drilling into the mica ring and mica bar at the intersection of the bottom of the bars and the mica rings. After drilling under the bar and mica I take a fine needle hook and proceed to scrape the bottom of the mica bar. The result is that this will as a rule remove the bug. In other words, I drill in to the spot where the mica is carbonized either in the mica bar or the mica ring, and then I scrape the carbonized matter clear of the commutator bars. After testing and finding the

bars clear I fill up the cavity caused by drilling and scraping with a good commutator cement and the repair is complete.

Another effective method that I have employed at times when the drilling failed or it was impossible to use the drill, was to take a piece of flat steel the same width and breadth as the mica between the commutator bars, place this upon the mica bar and tap it with a hammer until t[illegible] is driven down slightly below the level of the other bars. At times it is necessary to slightly loosen the front rings of the commutator to enable the mica bar to drive down a trifle. As a rule, however, this is not necessary, as the mica will drive down without the tightening rings being loosened.



I have often secured satisfactory results from this method. Generally, in driving the mica bar down a trifle it pushes the carbonized part clear of the copper bars. The space resulting from driving the mica down can then be filled up with commutator cement.

I have found that with the two methods described and a little perseverance, I am able to remove a large percentage of the bugs from the commutators without removing them from the armature and without taking them apart. I will admit that the methods used are not always crowned with complete success, but on an average I can state that they are successful nine times out of ten. They are therefore worth a trial any time.

Device for Bending Small Pipe

A device that has been used with success for the bending of pipe and boiler tubes, and that may have other useful applications, is shown in the accompanying sketch, described in the *American Machinist* by Stephen Jaross.

The iron base *A* carries a pilot roller *B* of a diameter of the required bend, reduced, however, to provide for the inevitable spring-back when pressure is removed. The pin *C*, which acts as a pivot for *B*, is also the fulcrum for the lever *D*, which carries at *E* a roller similar to *B*. The roller *E* is adjustable toward and from *C* to permit of the use of rollers *B* of varying size. At *F* is a clamp for the tube *G*, and at *H* a stop for the end of the tube. At *I* is an adjustable stop, which must be placed at such a point as will assure that the right angle of bend

SMALL PIPE BENDER

will be provided after the work springs back on the stress being removed. If a circle of a different diameter is desired, the roller *B* must be changed accordingly.

The grooves in the rulers *B* and *E* should be turned about 0.01 in. deeper than the radius of the exterior of the pipe. As the wall of the pipe is only $\frac{1}{16}$ in. thick or thereabout, it is necessary to reinforce it against collapse. This is done by filling it with fine, dry sand held in place by tight plugs at the pipe ends. The part to be bent is heated. The sand not only helps to keep the pipe in shape, but it aids in retaining the heat, so that the bend can often be made in one operation.

Some Random Notes on Electrical Trouble

By Jack L. Ball
Amsterdam, Ohio.

A ventilating fan was driven by a 10-hp., 250-volt, direct-current motor. When the mine load on the generator was heavy, the motor would slow down; in other words, the speed was governed by the load on the generator. The theory was advanced that the motor was too small for the work intended. A test was made, and it was found that it required just $4\frac{1}{2}$ hp. to drive the fan at its normal speed.

The greenhorn (?) would give no reason why, but when he substituted copper fuse wires of the proper size in place of the lead fuses that had been used, the trouble was cured.

A great deal of trouble was experienced with the brushes of a direct-current generator. Although they were well fitted to the commutator, they would burn and break around the edges. Upon examining these brushes, it was found that the mine electrician in fitting them was not removing the copper sheathing. This is an important point to watch, for this reason: Copper has a much lower resistance than carbon, and when the brush is worn sufficiently so that the copper comes in contact with the commutator surface, the current will localize at this point and will not be evenly distributed throughout the brush. This causes a burning and chipping away at the edges. The remedy is to strip back enough of the sheathing and see that at all times it does not touch the commutator.

Upon starting a 150-kw., direct-current generator one morning, it refused to generate. Someone had gotten the idea that before putting on new brushes it was necessary to boil them in machine oil in order to soften them. After the brushes and commutator were carefully cleaned with gasoline, the trouble was not repeated. In this case, when the commutator was warm the brushes had contact; but as soon as the machine cooled off a film of oil froze around the commutator, keeping the brushes from making actual contact.

Oil should never be used on brushes or commutator unless trouble is invited. If the brushes being used are too hard for the machine, get a softer brush. A safe guide is to write to the makers of the machine, stating what difficulties are being experienced. They will gladly make helpful suggestions.

A 250- to 275-volt generator was brought up to speed, and the voltmeter registered 300—its extreme range. It was found that about half of the resistance of the shunt field rheostat was burned out, and as it was but a few minutes until starting time, something had to be done quickly. An extra resistance column of a mine locomotive was connected in series with the rheostat, it being necessary to cut out about half of the resistance of the column to give the proper range. The column is still in use after several months' service.

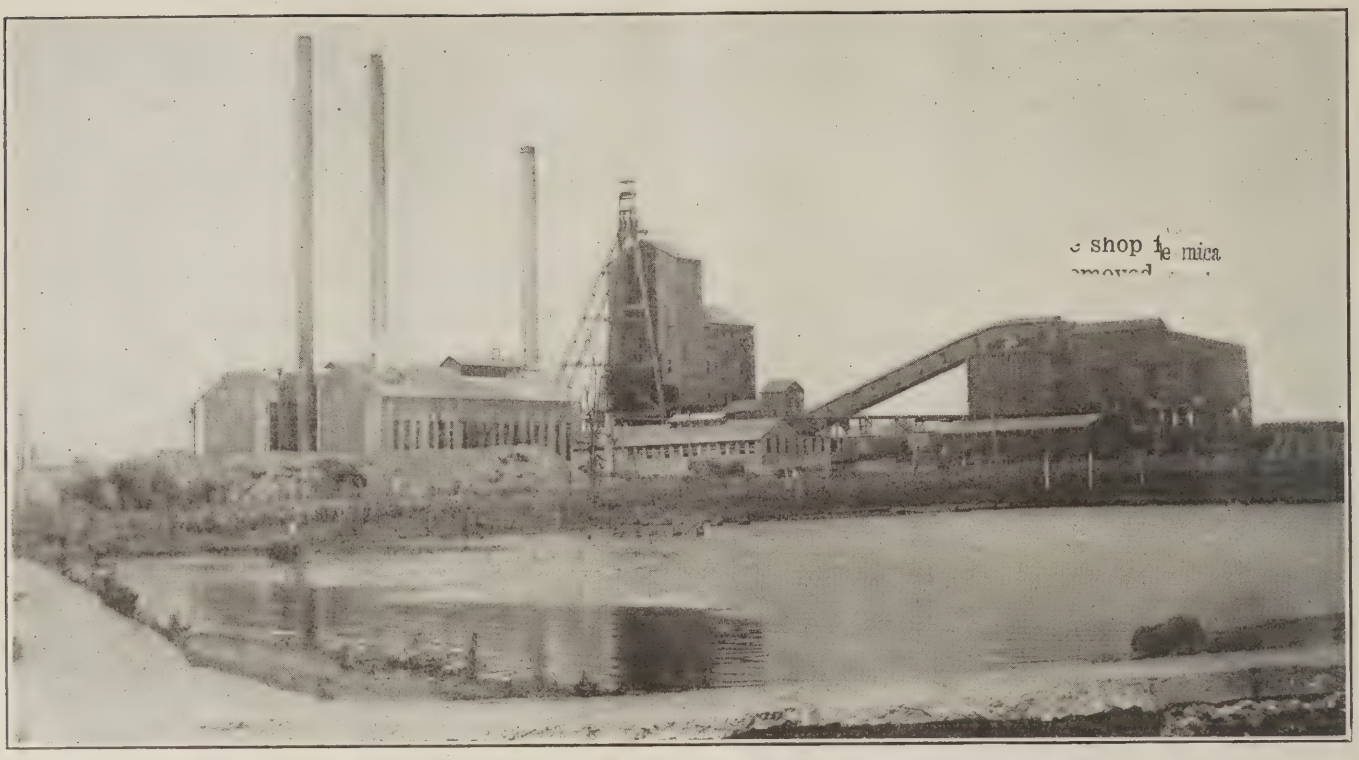


FIG. 1. GENERAL VIEW OF ZEIGLER MINE OF BELL & ZOLLER MINING CO.

New Plant of Pioneer Operation in Franklin County, Illinois

By GEORGE W. HARRIS
Editorial Staff "Coal Age"

PROBABLY few (if any) coal mines in the United States in the last quarter of a century have been more prominently advertised than the old Zeigler mine of the former Zeigler Coal Co. The real development of the Illinois Franklin County field dates from the time Joseph Leiter prospected and took over approximately 8000 acres of coal land upon which he located the town of Zeigler and developed the mines of the Zeigler Coal Co., now being operated by Bell & Zoller Mining Co., of Chicago, Ill. The subsequent history of this noted plant is too well known to require comment beyond reference to the stormy days when the mine was having such serious labor difficulties.

Coal history in Franklin County dates back about a third of a century, when a prospect hole was drilled for the purpose of finding coal in the vicinity of Benton, the county seat of Franklin County. It is stated that after drilling to a depth of 584 ft. the promoters of the enterprise became discouraged and stopped the drill. At the time prospecting operations were stopped the drill was within about 50 ft. of the No. 6 seam, and the failure to continue drilling probably greatly delayed development in southern Illinois.

A number of years afterward the late W. P. Halliday, of Cairo, Ill., prospected extensively in Franklin County, putting down drill holes and covering this territory systematically. Parallel rows of holes one mile apart each way thoroughly investigated conditions, but unfortunately the results of this investigation were not disclosed. After Mr. Halliday's death it was announced that his policy was eventually to take over a large area of the Franklin County coal which he had prospected and found of such high quality. The next prospecting, and the first one by which the general public was made aware of the rich seam of coal underlying this county, was made by some citizens of West Frankfort in 1896.

It is always interesting to note the successive steps in the development of such a famous field as the Franklin County coal region. In this development the Zeigler mine has always taken a prominent part. Probably the latest investigation of a practice which bids fair to assume importance in big production is along the lines of rotary dumps and skip hoisting. The Bell & Zoller Mining Co. has such equipment for large tonnage (Fig. 1) which has been modified as certain features of the original installation proved unacceptable to its requirements. In this connection the old bottom-dump mine cars have been replaced by solid-end cars; the rotary underground dump and skip have been retained, have been operating for a year and a half, and are a success. In the bottom dump car (Fig. 2) the dog would work loose while trips were en route to the shaft bottom, and the car would empty along the entry. This old car bottom included two doors, each 2 x 3 ft. in dimension, and there was a cross-bar in the center of the bottom. As the trip moved continuously over the dump the bottom was easily knocked open—that part was all right. But sometimes there was difficulty from large lumps of coal lodging in the bottom, and these had to be broken up or barred loose. This special Zeigler

installation and the whole matter of rotary dumps and skip hoisting has been fully covered by a most interesting article entitled "Hoisting Coal in Skips," by John A. Garcia, which appeared in the June 22, 1918, issue of *Coal Age*.

Comments on the practice of the Bell & Zoller Co. at its No. 1 mine are especially interesting when taken in connection with the new plant this company is developing two miles southwest of this operation. The Zeigler mine is close to the top of the leading producers of Franklin County. There are 21 mines in this county, which produced 11,317,657 tons of coal for the year ended June 30, 1917, out of a state tonnage of 77,412,-054 for the same period. At this time the Zeigler mine produced 1,065,359 tons of coal.

Substantial progress has been made at the No. 2 mine of Bell & Zoller. The main and air shafts are well down to coal, and a permanent steel headframe is in place at the latter shaft, together with a Litchfield hoisting engine which is being used to sink the shaft; also some of the permanent buildings about the plant have been constructed. Before the shafts were started diamond drill holes were put down to coal at the site of each shaft. This plan might seem to be an unnecessary precaution in the Franklin County field to some, but instances are on record in other coal fields where this policy would have saved a large amount of money, considerable time, and permitted a much better layout of plant. In one special case in mind, a number of drill holes were put down systematically covering a large tract of coal. The engineers advised the management to locate shafts, tipple and other surface plant on the strength of general information as to depth and condition of the seam to be worked. But no hole had been drilled at the proposed shaft location. It took an expensive main hoist shaft, considerable rock tunnel and valuable time to prove a serious disturbance to the coal at this point. Meanwhile a steel tipple and other modern buildings were practically completed on a layout fitting in with this hoist shaft and could not well be changed to suit other and better development. The shafts at this new No. 2 mine will not have steel buntons, as the management considers the injury done to such construction by falling coal to be a serious objection to the use of steel for that purpose. Wood buntons will be used here and made fireproof with concrete, strengthened and secured to the wood by metal lath and staples. The air shaft will have three compartments; an airway, stairway and a compartment for a cage hoist. The main hoist shaft will have two compartments. The cover over the No. 6 seam at these shafts is about 317 ft., or 100 ft. less than at the hoist shaft at No. 1 mine at Zeigler.

FIG. 3. STORAGE PLANT AT ZEIGLER MINE

FIG. 2. OLD BOTTOM DUMP MINE CAR AT FACE OF ROOM

The new mine will be laid out on the four-entry system, and the main entries will be north, south, east and west to fit the boundaries. The panel system is used in the old mine and a modified panel will be adopted for No. 2.

The middle entry pillar of the four entries will be left solid; there will be no breakthroughs, and the pillar will only be broken where entries cross it. This plan makes it much easier and safer to block off one side of the mine from the other. Also each panel is to have no connection with any other panel, but is to be

a proposition by itself. The new mine is to have a capacity of 5000 tons in eight hours, or about the same as mine No. 1. The mine car will hold 5¼ tons; the Zeigler car is a 4¼-ton car, and that would have been considered a novelty a few years ago. But in the Franklin County big-seam mines, where tonnage is sought and headroom is available, one way to achieve this end is to send trips of big units to the shaft bottom. Also, when coal is hoisted, quantity cargoes count; in fact big cars and double-deck cages or skips are practically essential when a mine aspires to large production.

At the new place a self-dumping cage of the Olsen type, manufactured by the Eagle Iron Works, of Des

FIG. 4. DRILLING A HOLE AT ZEIGLER MINE

Moines, Iowa, will be used. The Olsen cage is popular in Illinois, and it is significant that it is used at two other plants which are close to the top, not only on record daily production (5508 and 5502 tons in eight hours respectively) but also on yearly tonnage—substantially over a million tons a year, according to the last Illinois coal report. In connection with a change in policy from skip hoisting at mine No. 1 to self-dumping cage at the new operation, Robert Zoller, the general manager of the company, stated that breakage of coal in the use of the skip was not the reason for giving up that method of hoisting—that the breakage was not a serious matter. A self-dumping cage was preferred, as it gave a better opportunity to dock cars for dirt. When one car was dumped into a weigh hopper it was an individual lot of coal; if it was dirty, the man who loaded it was docked. When cars are dumped into a bin, or even when two cars are dumped into a skip direct, then individuality is lost. There is no opportunity in skip hoisting to send a condemned car of coal to the outside, shovel it out on the ground and show the loader the exact state of affairs.

In commenting on opportunity to dock dirty coal in skip hoisting, John A. Garcia, of Allen & Garcia, engineers, Chicago, Ill., states that ideal docking schemes are offered in skip hoisting—that there are two good chances with the skip to one with the cage to detect impurities in coal. First, Mr. Garcia states, cars may be tested at unexpected times so that the men may never know when a test will be made; or secondly, one car of coal at a time can be placed in the skip when the cleanness of the coal is questioned. Then the skip can be dumped at the top and the coal spread out on a wide feeder, where there is a better chance for inspection than in the case of the cage and weigh hopper. This can be done 20 times during the day, and the time consumed will be negligible—there is a world of leeway to do this in a day's run. A further comment was made that in a mine of 5000-tons capacity it would be a physical impossibility to comply with the miner's contract. That the only way in a big-tonnage mine is to watch a car as it dumps, pick off all impurities possible and then go and see the man who loaded the car and discipline him. The writer would suggest that with any system of docking, a foreman could readily go through the working places and notice where rooms or entries failed to have such impurities in the gob. If seam impurities are not in the gob, it would be well to examine cars from such places, for the chances are that the impurities are being sent out with the coal. Rotary dumps and skip hoisting are attracting considerable attention, are being installed in some of the big new plants not only in Illinois but in other sections as well, and the progress of this combination will be watched with considerable interest.

The No. 2 mine will be electrically equipped throughout. At the old mine 26 motors are in use of some of the leading makes—Jeffrey, Westinghouse, Goodman and General Electric; cable and reel gathering locomotives are used here. One lonely mule is kept to haul powder. Each panel includes 28 rooms; units of 14 rooms were decided upon to fit in with machine mining employed at No. 1 mine, 14 loaders being apportioned to each machine. Goodman mining machines are used at this plant, made by the Goodman Manufacturing Co., of Chicago, Ill. Pick men are placed in sections where there is a shale top and long rooms are to be worked.

In Fig. 4 is shown a man drilling a hole for a shot at the face of a room. The mining coal drill used here is the Hardsocg made by the Hardsocg Manufacturing Co., Ottumwa, Iowa. The height of the coal is well brought out and emphasized by the fact of his standing on a bench to reach the drill. If the man standing in the corner of the room is 5⅔ ft. high, the height of the coal might easily be 10 ft. Where electrical apparatus is used in the new plant, it is easily possible that those types which have given satisfaction in the older operation will be favorably considered for the new mine. The management contemplates having

every convenience for facilitating operations. An inspection was made of other plants, and good ideas which have worked out satisfactorily for others will be utilized when they will be an improvement over old methods.

A rescreening plant will be installed at No. 2 which will be a little larger than the one at No. 1. Ordinary Illinois coal preparation will be adopted, and any coal washing will be done by the gravity process—either by the Luhrig or Stewart jigs. Plans for the plant were made by the Link Belt Co., which will put in necessary coal and ash conveyors. Among other mechanical devices for simplifying operations will be stokers for firing boilers. Draft for the boilers will be furnished by a 240-ft. brick stack. All men and material will be handled through the air shaft.

A large amount of grading for the No. 2 mine yard has been done by a Marion dragline steam shovel (Marion Steam Shovel Co., Marion, Ohio) borrowing on both sides of the track to form the fill. An additional machine has just been placed on this job—a Bucyrus dragline machine—made by the Bucyrus Co., of South Milwaukee, Wis. It is the intention to avoid disturbance to the handling of cars by placing the car sidings above the high-water line wherever possible. The ground at the tipple will be filled up to the high-water line. From the tipple the empty tracks will be graded so that cars will run to the tipple by gravity; this will mean a maximum fill of 31 ft. on the siding and 14 ft. at the tipple. This arrangement will leave the lower end of the loaded yard at the high-water line. The tipple foundations will be secured by starting the footings below the fill and concreting through it to a point above the ultimate surface.

The Leiter interests own the coal and most of the surface at the Zeigler plants, and Bell & Zoller operate under lease. The lessor is building a town between mines No. 1 and No. 2 for the accommodation of the employees who will work at the new mine. A feature of some of the big plants in the Franklin field is provision to stock coal at times of insufficient transportation.

There will be no new storage plant at No. 2 mine, as there is an 80,000- to 90,000-ton plant for this purpose at No. 1 mine which will be convenient for use by mine No. 2. Fig. 3 shows a locomotive crane loading coal from this stock pile into the railroad cars at mine No. 1; the top of the tipple can be seen in the background. Bell & Zoller hope to get the new plant in shape by early next winter, but feel doubtful about being able to do so; labor is scarce and it is hard to obtain electrical machinery and supplies.

The officials of this company are: H. E. Bell, president; Robert H. Zoller, general manager. At the mine Joseph Yerley is superintendent; G. C. Breckenridge, mining engineer; Andrew Leslie, top foreman, and Edward Prudent, mine manager.

Coal Age Index

The indexes to *Coal Age* are furnished free to all who ask for them. The index for the first half of 1918 is now ready for distribution, and a copy can be had by addressing a post card to the Subscription Department of *Coal Age*.

Storing Small Coal

By M. Meredith
Liverpool England

The market for small coal in Great Britain being insufficient to absorb the present supply, which is unusually plentiful on account of the necessity for maintaining the output of large coal for national requirements, collieries in Northumberland, South Wales and other mining centers are having to stock the surplus. Trouble having been experienced with spontaneous heating and firing of the small coal thus stored, a meeting of the North of England Institute of Mining and Mechanical Engineers was held a short time ago to discuss the matter.

John Morrison, who opened the meeting with a paper on the subject, recommended, in the light of his own experience the following preventive measures: (1) Do not make a spread heap more than 12 ft. deep nor a conical heap more than 15 ft. high at the center of the cone. (2) Keep iron temperature rods in the heap at intervals of about 8 yd. and draw them out and through the hand daily to detect heating. (3) Whenever heating is noticed, trench the top of the heap by irregular trenches to a depth of 4 or more ft., for it is usual to find that heating commences at a depth of about 5 ft., and if left alone will spread downward until the coal fires. (4) In addition to trenching, work a long tiff bar or poker into the heap so as to form funnel-shaped orifices at intervals. (5) Rake the whole surface of the heap periodically in order to break up the surface exposed to the weather. (6) Tread the heaps as little as possible. (7) Do not form coal heaps on marshy ground.

In the subsequent discussion several speakers advocated pipes down which a thermometer could be lowered, as preferable to rods, on the ground that the pipes give more certain measurements, and at the same time allow of the escape of heat.

Various additional suggestions were put forward. Professor Knox, of the South Wales School of Mines, recommended that wherever possible the coal should be sized before stocking and that each size should be put in a separate heap; that where it is necessary (on account of lack of space) to store "through" coal or mixed smalls to a greater height than 13 ft., the material should be laid down in succeeding layers of not more than 3 to 4 ft. each; that perforated ventilation pipes 3 to 4 in. in diameter should be inserted, one pipe to every 300 sq.ft. of surface, the lower ends of the pipes being at different heights from the ground throughout the stacks; and that coal should never be stacked behind wooden structures, or on ground covered by coarse vegetation like bracken, and that wet small coal should not be mixed with the dry coal, but dumped around the edges of the stack, where the air could get to it freely.

The treatment recommended by Professor Knox for heaps which have begun to smoke is to sink a series of small "shafts" about 10 ft. deep on the top of the heap, and allow a plentiful supply of water to pass into these and find its way through the heated zone. The shafts should be kept flooded with water until the height of the heap can be reduced to such an extent as to render further heating improbable.

An Innovation in the Coke Industry

By JOHN L. GANS
Connellsville, Penn.

THE entrance of the W. J. Rainey interests into the realm of byproduct-coke manufacture, through becoming joint owner with the Alan Wood Iron and Steel Co. in the construction and operation of a 330-oven plant of the Koppers type at Swedeland, Penn., marks a distinct departure for the beehive-coke producers of the Connellsville region. By the same token it bears record of the fact that the owners of Connellsville coking coal have recognized an opportunity and, after long and mature deliberation, have decided to take advantage of it. No less significant is it as a new trend in the expanding development of the byproduct-coking industry.

With the exception of a few merchant byproduct installations more or less distant from the Connellsville region, the construction and operation of ovens of this type has been limited to iron and steel manufacturing interests which are normally their own consumers. Connellsville operators have been without interest in these enterprises other than as producers of coal which they sold in its raw state in lieu of beehive coke which they formerly sold, and oftentimes to the same customer, as a manufactured product. The joint undertaking, in which the largest independent manufacturer of beehive coke and owner of Connellsville coking coal becomes the partner of a steel manufacturer in the production of byproduct coke, both for the use of the latter and for sale to other merchant furnaces in the Schuylkill and Lehigh valleys, is therefore the first step in a more intimate union of interests between the Connellsville region and the byproduct industry.

Connellsville Produced Byproduct Coal

Ever since the byproduct oven has attained importance as a factor in the manufacture of metallurgical fuel, the Connellsville region has supplied a constantly increasing quantity of raw coal for conversion into coke by the retort process. Until the organization of the Rainey-Wood Coke Co. the relation existing between the operators of the Connellsville region and the operators of byproduct ovens was merely that of seller and buyer. The latter needed a commodity the former was able to produce, but not always in the quantity desired. In the new enterprise the relation has been broadened to include, on behalf of the erstwhile seller of Connellsville coal, the interest of part ownership in the business of making that coal into byproduct coke, thereby constituting an innovation in the industry.

Some years ago, and not many at that, a suggestion that a Connellsville operator enter the byproduct-coking field would have been adjudged as little short of disloyalty by many members of the beehive craft. The reasons therefor were the decidedly unsatisfactory showing made by the pioneer byproduct plants and the generally unfavorable impression made by the results of their operation upon both the makers and users of coke in the United States. The original plants labored under all the difficulties and handicaps incident to the formative stages of all new industrial processes. The quality of their product, which has always been compared with Connellsville beehive coke as the standard, was inferior in size, color, cell structure, burden-bearing and other qualities by which discriminating consumers appraise the value of a coke.

After a thorough investigation into the operation of the early byproduct plants and the existing state of the art, the Connellsville operators became convinced that they had little to fear from competition in the markets hitherto exclusively supplied by them. At the same time they were not able to wholly dispossess themselves of the feeling that the newcomer was an unbidden guest at the metallurgical-fuel banquet table, and might develop a very vigorous appetite. Likewise did they agree that no advantage, and certainly no profit, would arise from the construction of byproduct plants in the Connellsville region, and the abandonment of the beehive oven, even though the latter would soon become antiquated and always had been inefficient and wasteful. They realized that without a consumer of oven gas immediately at hand, which the Connellsville region did not have, byproduct ovens built at the mines would in reality be even more wasteful than beehive ovens, and infinitely more expensive to build. Hence they saw, in the early stages of the byproduct oven's development, little more than a means of augmenting, with a low-grade coke, the fuel supply of a furnace here and there, little dreaming of the possibilities of the newborn industry when stimulated to expansion by a world war.

The Chief Byproduct Was Gas

In the period of its infancy, through which the byproduct oven passed rather slowly, comparatively little effort was made to utilize the byproducts other than gas. In fact, the market for byproducts had not been created. As American engineering genius and skill later brought the byproduct and recovery processes to perfection, and the market for byproducts became wider and more diversified, the beehive operators did not fail to note that the industry began to assume proportions and to take on new phases. When, in 1915 and later, the number of byproduct ovens began to increase so rapidly, and the Connellsville region was brought face to face with the fact that beehive coke was being replaced in many quarters and in large quantities, no little concern began to be manifested as to the ultimate effect upon the manufacture of beehive coke, particularly in the Connellsville region.

Meantime it had been observed, however, that coincident with the increase in the number of byproduct ovens there had been an increased demand for Connellsville coal as the raw material for making byproduct coke. But in that situation, which was beginning to be recognized as presaging a change in the character of the Connellsville region from a producer of coke to a producer of coal, the operators were confronted with freight differentials which placed them at a decided disadvantage with immediately adjacent and competitive coal-producing districts. These differentials were an

inheritance from the fathers of the Connellsville region's principal industry. In their day and generation Connellsville coal was esteemed altogether too valuable to be applied to any other use than the manufacture of beehive coke, and they had persuaded the railroads to penalize the shipment of coal outside the region. Joining for defense in a common cause the independent producers early in 1916 formed the Connellsville Coal Tariff Association, with the removal of the rate discriminations as its immediate purpose and object. After the presentation of what is conceded to be one of the best prepared and most skilfully conducted cases before the rate-regulatory bodies, practically every contention of the association was supported and the whole region was placed upon an equal footing with its neighbors in the matter of freight rates on coal to the byproduct-coke manufacturing centers.

Operators Do Not Oppose Byproduct Coking

Their position being thus strengthened, the Connellsville operators were able to view with more equanimity than before the actual and prospective inroads into their coke trade by their passive and sometimes active byproducts competitors; more so because of the dependence of the latter upon the Connellsville region for a large part of their raw material. While the progress of the war has demanded an output of beehive coke to the limit of the Connellsville region's capacity to produce, as well also of the byproduct plants, the interests of the former have been centering their energies upon the things of the present, but not without some thought and probably some speculation as to the things of the future. The desirability of making an alliance with steel-producing interests in the manufacture of byproduct coke at the point of consumption, to which coal would be shipped from the Connellsville region has, no doubt, been given more or less consideration in the councils of the larger merchant operating companies. Whether or no this has happened, it has been reserved to the W. J. Rainey interests to take the initial step in that direction.

Considered from an economic viewpoint this step is merely an adaptation to the conditions which are developing in consequence of the expansion and growth of the byproduct industry and the transformation that is gradually taking place in the Connellsville region. While there is certain to long remain a demand for beehive coke, and the Connellsville region will retain its preëminence as the producer of it, the region will continue from year to year to undergo a change from a coke-manufacturing to a coal-producing center. The transition will be easily accomplished, the process involving little more than suspending the operation of the beehive ovens and centering plant activities on the mining and shipping of coal to the byproduct plants. This evolution, or revolution as some may term it, has been in progress for some time and cannot be said to have detracted from the importance of the Connellsville region as a fuel-producing center. In fact, without the extensive mine development of the Connellsville region the rapid growth in the byproduct industry would not have been possible, such development having provided an immediately available source and ample supply of coal for the new byproduct plants as they were made ready for operation.

The pig-iron and steel producers who have also become byproduct-coke producers early realized that Connellsville coal sustains the same important relation to the manufacture of a high-grade byproduct coke, rich in byproducts, that it does to the manufacture of a high-grade beehive coke. Through becoming a producer of byproduct coal the region has only changed in character, not in importance, in its relation to the iron and steel industry. This fact insures the continued activity of the Connellsville region as a fuel-producing center and provides opportunity for the beehive-coke producers and owners of coking coal to become interested, as the Rainey estate has done, in the enlarging activities of byproduct-coke production.

Automatic Caging Saves Labor

By W. A. Brown
Bowerston, Ohio

There never was a time in the history of the country when it was so necessary to conserve labor as now. Not only is this necessary at this time, but it will doubtless remain so for many years after the war is over. Our own people have been taken away from our industries, and the source of supply upon which we have always relied—immigration—has been cut short. After the war is over the foreigner, upon whom we have heretofore depended, will doubtless find work in the reconstruction of his own country, while many of our boys who in the natural course of events would enter the industries will never return.

This condition of labor shortage has been anticipated by the producers of the country, who are putting forth every effort to bring about a maximum production with a minimum amount of labor. Every sort of labor-saving device is sought after and brought into use.

In no field are these labor-saving devices more imperative than in mining. Only a few years ago—well within the memory of middle-aged men—undercutting machines were practically unheard of. Today most of the bituminous coal mined is cut by machinery. Mechanical devices are employed in every step in the handling of coal. Today coal is gathered from the rooms and hauled by motive power to the tipple or shaft bottom, as the case may be, where it is caged or fed automatically onto the dump or cage.

The automatic feeding of cars onto a cage or dump is being done with so much promptness, simplicity and with such a saving of labor that one who sees it for the first time is astonished, comparing it, as he must, with the old method where two men, or as was sometimes the case as many as could get around a car, pushed it onto the cage. These men who pushed the cars onto the cage or dump are released for other work where automatic cagers are employed. The transfer of these men is not the only gain, as the cars are fed with a promptness and rapidity not possible with hand feeding.

Knowing that success must follow specialization, the Mining Safety Device Co. centered its efforts for eight years on the automatic handling of cars at the shaft bottom and on tipples. This singleness of purpose has made possible the general satisfaction that its machines are giving.

COAL SHOT DOWN READY TO BE LOADED OUT

Coal, Explosives, War—III

By H. J. BROUGHTON
Wilmington, Del.

SYNOPSIS—*In shooting coal it is important to have as many free faces as possible; consequently, undercutting or side shearing not only aids the explosive but relieves the roof. Shooting from the solid requires more explosive per ton of coal dislodged than does shooting after undercutting, and also shatters the coal more. It is liable to weaken the roof and render it dangerous. The method of priming a charge has much to do with both its safety and effectiveness.*

BLASTING powder is the most economical and satisfactory explosive for most coal blasting unless mine gas or coal dust is present in dangerous quantities. It is strong enough to blast even the hardest coal from "the solid," provided the boreholes are given the correct location, direction and charge; and its velocity of explosion is so comparatively slow that it does not crumble or shatter the coal. To reduce shattering and increase the quantity blasted per pound of powder, soft coal should be undercut. Where this is not practicable, side cutting or "shearing" may be done before the "breaking-in" shot is made.

When shooting from the solid there is only one free side, and as the blasting powder must break the coal on all other sides a larger and therefore more expensive charge is required for the amount of coal blasted. Furthermore, the coal is shattered more than if it had another open face from undercutting. In "slab shooting," and all other shots after the breaking-in shot, the undercut gives three free faces and accordingly reduces shattering and increases the quantity of coal blasted per pound of powder.

Shattering can also be reduced by using course-grain blasting powder, as the large granulations explode more slowly than the small ones. Shattering may also be reduced by means of "air shots." These not only reduce the shattering effect on the coal, but often cause the force of the explosion to spread farther laterally and bring down a larger quantity of coal.

To blast coal successfully and economically the charge must be located in just the proper place, and must consist of exactly the right quantity and granulation of blasting powder. These are governed entirely by the conditions of coal to be blasted by the shot—the number, size and position of bands of slate, "bone," sulphur or clay, the quality and condition of top and bottom, the presence and position of clips and seams, whether the coal is solid, undercut or sheared, whether the work is on the faces or on the butts, whether the coal is hard, medium or soft, the height and width of the face to be shot, etc.

The borehole must be so placed and pointed that it will be no easier for the charge of explosives to break to one free face than to another. This does not necessarily mean that the charge should be the same distance from each free face, because coal may break much more easily in one direction than in another.

When better work will be done by putting the charge all in the back of the hole, drills or augers of large diameter should be used. Under other conditions it is preferable to have the charge spread along more of the boreholes. In such a case a hole of small diameter is necessary, but never so small that the charge comes too close to the mouth of the hole to be properly tamped.

The amount of the charge should be just great enough to crack and break to a maximum distance laterally,

and to each free face simultaneously. When the charge is so located that less force is necessary to break to the mouth of the borehole than to any other free face, the result is a "blow-out" shot. If it is in such a position that there is much less resistance to the undercut or some other free face, the result may be a "windy" shot. Holes are generally from 1 to 2 in. in diameter, and from 3 to 6 ft. deep.

In anthracite mines the hole for the cut or breaking-in shot may be drilled in any part of the breast face. This makes a second free face, and all subsequent shots should leave an irregular breast face, so that each shot may have the benefit of two free faces. In the gangways the depth, position and direction of the boreholes are governed by the quality of the coal and the thickness and pitch of the bed.

When blasting in bituminous mines, and in rooms that are undercut, the hole for the breaking-in shot is generally started a few feet to the right or left of the vertical center, and pointed upward and toward the far side, so that the point of the hole will be about halfway between the two sides or ribs and 2 ft. below the top or some heavy band of slate or sulphur. The holes for the following shots are located so that the points will be somewhat higher than the point of the breaking-in hole, and as far away from it laterally as the force of the powder will carry. Sometimes a hole on each side, fired simultaneously by electricity, will give best results. In many bituminous coal mines two or three shots will bring down the entire chamber face.

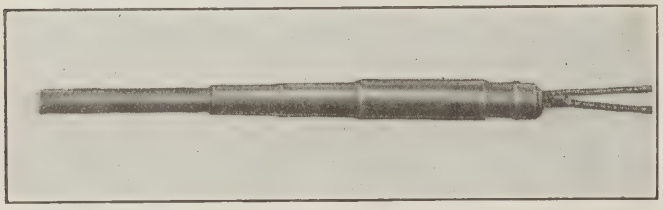
Entry blasting in bituminous coal mines must be adapted to the coal conditions, whether the entry is on the face or on the butts. The charge of blasting powder required in coal may fill from 1 to 3 ft. of the borehole.

Blasting powder is the principal explosive used for blasting where the rock and earth covering of coal is being removed. In some places, where solid earth with large boulders has to be removed, blasting is done in small horizontal tunnels, known as "gopher holes," driven into the bottom of the face for 20 or 30 ft. These holes are sometimes made 2 ft. in diameter, so that the man digging them can drag himself to the rear and dig a small crosscut for the blasting powder. Others are dug with long-handle shovels and bars, and are but 8 or 10 in. in diameter. Tamping is tightly packed from the charge to the mouth. Charges are exploded electrically with a 40 per cent. dynamite primer.

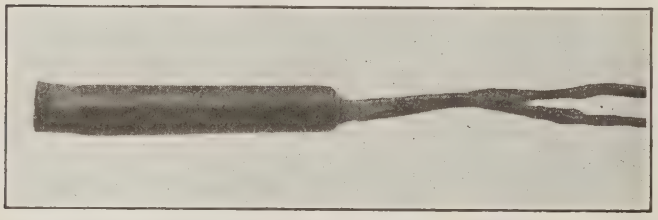
Ever since blasting powder first came into use, the advantage of igniting the charge in the center has been evident to all, particularly when this charge is distributed for a foot or more along a borehole of comparatively small diameter.

When a charge of blasting powder in a borehole is ignited at one end, it is always possible for some of the coal to fall before the entire charge is exploded, and thus cut off for an instant the remainder of the charge. This is most likely to happen when large charges are ignited at the end nearest the mouth of the borehole. In such a case more or less of the powder at the back of the hole, where the burden is usually the heaviest, does little execution, and a large flame and a great volume of smoke are projected into the working place.

Attempts to ignite the charge at the center are sometimes made by extending the fuse to that point; but this is seldom successful, owing to the fact that most fuses will spit fire from the sides and ignite the charge where the fuse enters it. Even the very best triple tape and gutta-percha fuse will do this occasionally. The expense attached to the use of the highest quality of fuse has caused this method of igniting charges of blasting powder in boreholes to be practically abandoned.



"Miner's squibs," often used for igniting blasting-powder charges in boreholes, are sometimes uncertain in their rate of burning, and may give but little time for the blaster to reach a place of safety after lighting them. This makes it necessary, when a number of shots are ready to be fired, for the blaster to return to



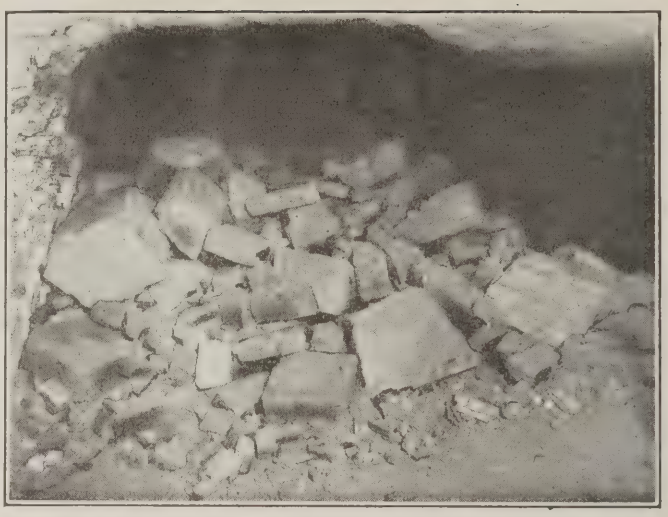
LIGHTING THE FUSE FOR A SHOT IN A FACE THAT HAS HAS BEEN UNDERCUT BY MACHINE

the face several times, causing the loss of valuable time. All of these disadvantages are overcome by the use of the electric squib. These squibs are similar in general appearance to electric blasting caps, but have a heavy paper cap instead of a copper one. The charge in this cap does not detonate like that in electric blasting caps, but merely shoots out a small flame. When electric squibs are used, the charge of blasting powder can be ignited in the center, giving a little quicker and stronger action, and insuring the explosion of the entire charge before any of the surrounding material can fall and cut off a portion of it. The borehole, too, can be tamped solid, leaving no vent for a partial loss of the strength of the powder. When the entire charge is exploded at once, less smoke is given off by the explosive. This, with the elimination of smoke from burning safety fuse, results in purer air, making it possible for both miners and draft animals to do more work.

Other advantages in the use of electric squibs are that when more than one shot is to be fired all the boreholes can be connected in series and fired at the same instant, resulting in a considerable saving in both

DELAY ELECTRIC IGNITER

ELECTRIC SQUIB



powder and time. Shotfirers can thus cover a great deal more ground than when using fuse or miner's squibs.

It is much safer to blast with electric squibs than with fuse or miner's squibs, because shots are not fired until every one, including the blaster, is a safe distance away, and because danger of hangfires is entirely obviated.

In short, the advantages gained by the use of electric squibs may be summed up as follows: More work from a given amount of blasting powder; everybody out of danger before the shots are fired; no waiting—the firing is instantaneous; any number of shots can be fired simultaneously; no fumes from burning safety fuse; a minimum amount of smoke from the blasting powder.

In connecting up electric squibs for firing, the wires, where joined, should be clean and bright. Connections should be made in series in the same manner as those of electric blasting caps.

Electric squibs require the same storage conditions as electric blasting caps, and although they cannot be exploded by shock or concussion like electric blasting caps, they must be handled just as carefully, for their

RESULT OF SHOT IN WEST VIRGINIA COAL

construction is necessarily delicate, and they can be easily broken by rough handling.

Delay electric igniters consist of a copper tube about 3 in. long, into one end of which is inserted and fastened the igniting material, bridge wire and the two wires connected to the bridge wire. Into the other end is crimped a piece of fuse that may vary in length from 2 to 12 in. When it is desired to have a period of delay between the firing of different charges of explosives, this can be accomplished by using an igniter of the shortest length fuse in the charge desired to fire first, the next length fuse in the next hole and so on.

The fuse in the igniters is ignited from the material surrounding the bridge wire, the delay period being brought about from the different lengths of fuse. These igniters can all be connected in the same series and fired by means of one application of the electric current.

When used with blasting powder, it will be necessary to have only the end of the fuse in the charge; for if the entire length of fuse is placed in the blasting powder the latter is apt to be ignited from the side spit of the fuse, and consequently the purpose for which the igniters were used will be defeated.

Delay electric igniters are made with copper wires of any length, but when iron wires are used they are only made either 4 or 8 ft. long. They are dipped all

RESULT OF SHOT IN ALABAMA COAL

over in a waterproof paint. This covers the ends of the fuse as well as the rest of the igniter, and prevents the powder in the fuse from absorbing moisture from the air. The fuse is made ½ in. longer than necessary, so that ½ in. of the end must be cut off before inserting into the blasting cap or the charge of blasting powder.

The importance of using reliable blasting supplies cannot be overestimated. The failure of explosives to perform their functions most effectively is, in many cases, due to defective or weak detonating agencies. In the selection of blasting supplies for firing the explosives, the greatest care should be exercised. The lives of employees should not be imperiled nor property endangered by attempting to fire charges with weak, improperly made detonating apparatus. To be sure of results, reliable blasting supplies should be employed.

Every explosion prevented in a mine through the paying of more attention to technique of operations in blasting probably saves the services of a certain number of men, who instead of being laid up in hospitals, can be more profitably employing their time in trying to improve their methods.

For this work of shotfiring at the mines there must be employed men who have enough patriotism to use every ounce of available energy to produce a maximum

A RIB SHOT

of coal with the least expenditure of time, labor and material. Operators must be made to realize that unpatriotic foreigners will not meet this requirement. Efficiency and competency are the qualities that must be possessed by the worker who is to be counted on to improve the technique of his blasting operations.

With the constant improvement that is going on in the manufacture of explosives there is being brought to the attention of investigators, employed by the manufacturers, easier, simpler and more efficient ways of using explosives in the mining of coal. They make exhaustive tests of the manner of priming, tamping and loading. All this knowledge is compiled in concise form and published by the different manufacturers, who at all times are willing to supply the operators and miners with booklets setting forth the facts.

There are no methods employed by the mine worker which cannot be improved upon if study is given to the subject. The various booklets referred to above contain the meat of the subject with which they deal, so that unnecessary time does not have to be spent in searching through lengthy volumes to gain this knowledge.

Mine operators should see that booklets containing all available information on up-to-date methods of blasting coal are placed in the hands of every man handling explosives. A little thought and study of methods, together with their proper application, will do much to aid in the increased production of the coal so necessary to keep the wheels of industry moving, the homes of our nation warm, as well as to supply almost every needed article for the successful prosecution of the great world war.

Waterproof Plunger Grease

By L. W. Brooks
Jersey City, N. J.

Coal mining, like other industries, is seriously hampered by inability to obtain enough men to get out the great amount of tonnage now in demand. This difficulty will increase with the still larger need for coal next winter. It is a serious problem, and it will not be solved unless drastic action is taken by the authorities.

In times like these every man and every piece of machinery must operate at highest efficiency, and there must be no breakdowns. Machinery is doing its part, but can continue to do so only by careful handling and constant attention. Shutdowns cannot be tolerated.

In the old days machinery did not always receive as good attention as common sense would dictate, especially in such matters as lubrication. Poor lubrication was responsible for most of the repairs and faulty operation. By this is not meant that cheap lubricants were used, but the opinion is held that the proper care was not used in selecting suitable lubricants for each class of service. Cheap oil or grease may be deemed satisfactory in some cases, such as for the machinery in the breakers, but the power house, hoists, cables, mine pumps, etc., require lubricants selected with special reference to the service. Even high-priced lubricants may be a failure if they are not designed to meet the conditions under which they are used.

To illustrate this point, consider reciprocating mine pumps handling dirty water. Grit works into the packings and acts as an abrasive on the plungers, scoring them badly. It also cuts out the packings, so that they are an endless source of trouble. Packings cost money, and it takes time to replace them. Neither common black oil nor high-grade cylinder oil will stop the excessive wear, because neither has the necessary characteristics. The problem is not solved merely by buying more expensive lubricant.

The first consideration, therefore, is the fitness of the lubricant for the purpose; the price is secondary. Study each machine separately. In the case of mine-pump plungers the lubricant should be waterproofed so it will not wash off. It must be adhesive so the packing will not wipe it off and a man be kept busy applying it. Such a necessity wastes grease and time too. It must be of heavy body in order to maintain a film that protects the plunger from the cutting action of grit. It should contain flake graphite to counteract the effect of grit and add weeks to the life of the packing. Such a lubricant is cheap at any price.

In a similar way the kind of lubricant most suitable for wire cables, for car wheels, for haulage locomotives, for pneumatic tools, etc., may be determined.

Mine Accidents

By F. G. JARRETT
Anchorage, Alaska

SYNOPSIS—*Much has been done to increase the safety of mining on paper, but possibly decidedly less underground. This is believed to be due to the faulty, or at least in some respects objectionable, manner in which the tenure of office of mine inspector is determined. Is there not a better method of selecting and retaining mine inspectors than by election?*

THE readers of *Coal Age* and mining men in general have for many years discussed and written articles pertaining to firebosses, safety and mining inspections. Some of these articles have been along intelligent lines, opening a vital subject, which I am sorry to say was closed before being properly cleansed, as it were, leaving us in practically the same position as heretofore.

In addition to all our well-directed efforts, we are being deluged with "safety-first" signs, which are plastered in and around the mines in every conspicuous place. We point with pride to the wonderful strides made with the first-aid and mine-rescue teams, to the advancement made through education, together with dozens of new laws and inventions. But, can we point with pride to the death and accident statistics?

Men are still being killed and maimed, by falls of rock or coal, due, in many instances, to negligence on the part of the miner, to unsystematic timbering, or to the inspection department. With all our knowledge of mine gases, and our boasts of mine ventilation, blue-scarred faces, shrivelled ears and hands are still in evidence. Explosions still claim their toll.

We are confronted with that pertinent question, What's the matter? Are we in a rut? In other words, does all our mining experience, which has been indeed dearly acquired, stand for naught?

Present System Has Many Shortcomings

The old adage of prevention versus cure is surely applicable here. Owing to the fact that the fireboss, foreman and inspectors are always involved in accident cases, the logical solution to my mind hinges on and around the inspection end of the business. But can we justly blame anyone? The fireboss has to be a jack-of-all-trades. If a success, he is called a "hustler." The foreman gets and holds his job through his practical knowledge of mining and his ability to "make good" at getting the coal out. In large mines it is impossible for him to visit each working place every day. The inspector comes about once each month. He has to be firm and fearless and pray hard every election.

The question arises, Is this system conducive to mine safety? Should an inspector, after many years of practical experience, if he be a capable and fearless man, be ousted with a change in politics? Why not hold strict competitive examinations, pick out the best men, grading them down to the fireboss, and allow them to fill these positions as long as they do their duty?

The fireboss, being essentially a mine inspector, should be classed as such, coming strictly under the jurisdiction of the state mine inspector. He should deal strictly with mine safety, be in a position to enforce the laws in his mine or section of the mine, leaving questions of output to the foreman and his assistants. The fireboss, or rather we will call him a "safety inspector," should be placed under the supervision of the state inspector, to whom he should report and be responsible. With these safety inspectors recognized as a unit of the inspector of mines department, they should be able to show a decrease in the accident rate, at the same time preparing themselves for higher positions. When an opening occurred these safety inspectors should, if qualified, step up and keep going to the top, irrespective of politics and favoritism, which have been pernicious in the past in our inspection departments.

Progress Means the Saving of Life

Progress along these lines should bring its reward by saving lives. It should be a help rather than an impediment to the management, by helping to take a load of worry off the foreman's shoulders.

Due to the large territory assigned to the different state mine inspectors, they are unable to play a very important part in the detail work of mine safety. This, in addition to the fact that the fireboss is often otherwise engaged, places the workmen in the position of being at liberty to exercise their own ideas. We have thousands of miners in our midst who cannot read a safety sign, or a word of English, and consequently know absolutely nothing about gases, safety signs, or why a safety lamp is safe. Miners become so accustomed to danger that unnecessary risks are taken daily for the sake of a few cents or a few minutes. I have taken them myself and have seen hundreds of others do the same. Every miner can cite cases of leaving his timbering until the last moment, or of taking other chances just as foolish.

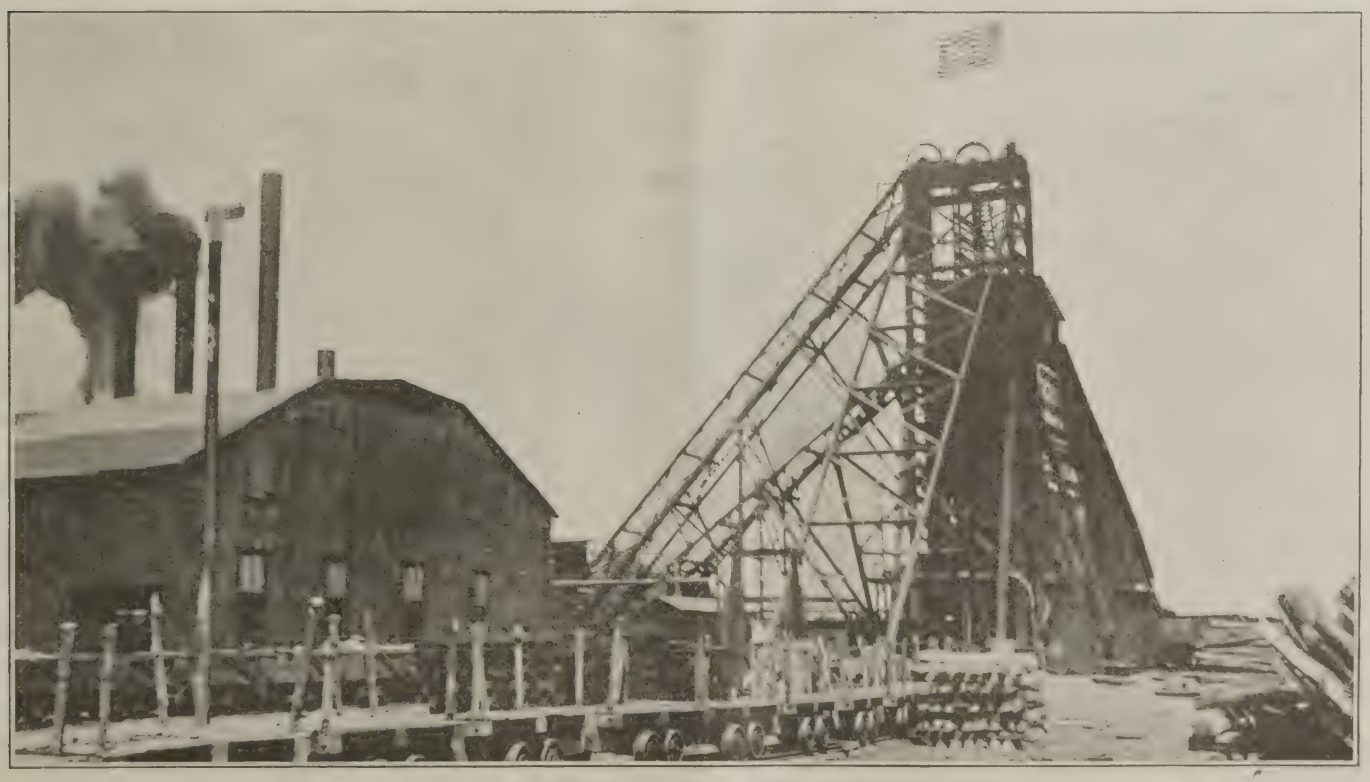
Higher wages attract unskilled men, who are, on account of shortage of trained miners, often put to work in mines, taking a chance on their own lives as well as becoming a constant menace to every other man in that mine.

I will cite one case, which I handled personally, and although many years have passed the incident is still fresh in my memory. Upon going my rounds in one of the most dusty and gaseous mines in this, or any other country, I entered the last room on a split, which was being worked by two foreigners. My senses warned me as soon as I stepped through the door in the crosscut and into their room that something was wrong. Glancing toward the face a distance of 40 to 50 ft. I could see the shapes of these two miners in the dust working like frenzied fiends, shoveling coal into a car. But what made my heart stop, or rather jump into my mouth, was their safety lamps. In addition to their lamps being on the floor, instead of hanging to a post, the flames of both lamps were nearly to the top.

As will be evident, those lamps were nearly red hot, and little time elapsed before I had them out into the fresh air, leaving these would-be suicides, or rather murderers, to grope their way out in the dark. Sitting down on the side I suddenly felt tired, and years older. Presently the miners came along jabbering apologies. This nearly made me see red, but keeping a strangle hold on my nerves I asked them—Why, etc.? They answered, We load 'ums' car, Mr. Boss, and then 'loka' see."

This, and other cases which have come under my observation, such as firing shots in bodies of gas, shooting on the solid, working in gas until rendered unconscious, smoking in gaseous mines, mining (undercutting) without sprags, working under bad roof, etc., have convinced me that our safety system is open to a lot of criticism. These weak spots can easily be repaired by a get-together spirit among the mining fraternity which will culminate in not only the saving of dollars, but in reducing the number of cripples, widows and orphans. Negligence and ignorance are our two worst enemies. One man through either of these openings can endanger his own life, and at the same time jeopardize the lives of every other man in the mine.

In conclusion, I will state that one suggestion is worth a dozen find-faults. I have thought the matter over and followed the dictates of duty by giving the idea for publication to be taken at its worth. Whether the subject is open and worthy of discussion, or not, must be decided by others.



Plant Operates by Storage

The plant of the Security Coal and Mining Co. is about three miles south of Duquoin, Ill., on the Illinois Central R. R. This is one of the mines operated by Rutledge & Taylor, a firm having offices in Chicago and St. Louis. About eight years ago this company bought a wooden tipple in Indiana, moved it to Illinois and installed it at the mine in question, as shown in the accompanying illustration.

While not one of the largest mines in the state, it made a good showing for the year ended June 30, 1917, when it produced 550,261 tons of coal. Of this amount, 20,932 tons were used at the mine, or about 4 per cent. of the total production of the plant. This seems like quite a modest demand on the resources of the company compared with the requirements of most Pennsylvania anthracite mines, which often use 10 to 11 per cent. of production for power purposes at the plant.

The Security mine worked 179 days during the year 1916-17. The coal here is entirely machine mined, 12 mining machines doing the undercutting. The coal is hauled to the shaft by 17 motors, while 35 mules assist in gathering from face to main partings. During last fall transportation reached such a state of inefficiency that the men at this mine were only working from two to three days a week. Finally, the company purchased the necessary equipment and arranged to dump coal in a field adjoining the plant.

A storage bank was started last fall close to the Security mine. This was added to until about Feb. 1. When the railroad did not furnish cars, run-of-mine coal was run through the tipple and loaded into side-dump cars of 20-ton capacity, by means of which the coal was dumped out on the ground for storage. On Feb. 1 there were some 90,000 tons of coal in the bank. About the middle of April the Illinois Central R. R., having acquired the stocked coal, began to load it into railroad cars. A siding was laid along the bank and coal was loaded into railroad cars with a steam shovel. On one special occasion, 35 flats were loaded in this way in one day. This plan not only enabled the company to hoist more regularly, but after the storage bank was instituted the men worked three to four days a week.

TIPPLE AND POWER PLANT AT THE SECURITY MINE

Handling Mine Water

By HENRY E. COLE
Pittsburgh, Penn.

SYNOPSIS—*The work that a pump must perform, the character of the water to be handled, the ultimate position in which the machine will be placed, its efficiency and service—all must be considered before a pump is purchased. Frequently, in times of emergency, various makeshifts may be resorted to to keep the mines in operation.*

AMONG the big problems of the coal-mine operator in securing maximum production is the successful handling of the mine water. The quantity of water to be moved varies according to the general locality; the depth of the coal; the character of the overlying and underlying strata; the area of the water shed; the season of the year and the amount of rainfall. In some mines little water is encountered, while in others 20 or more tons of water must be taken out for every ton of coal.

In this article I will not try to deal more or less exhaustively with this subject, but mention chiefly some things which result from study and experience, and hope that the matter presented can be used with good results.

Since the water problem is of such importance, the proper selection of pumping equipment is imperative and the following points should be taken into consideration: Work to be done; character of water; ultimate position of pump; efficiency; service.

By work to be done is meant the use to which the pump will be put. This will be either unwatering the mine, gathering from the face of the coal or from local dips, or main pumping—that is, taking water from a central basin or sump and discharging it outside of the mine. The number of gallons per minute and total head are also considered under this heading.

The character of the water must be considered in order to secure a pump which will last a reasonable length of time. If highly acidulous water must be handled, an effective acid-resisting metal or iron properly protected should be considered. If water contains sand or gravel in suspension, rapid wear on the parts exposed to high velocities will result. Often pumps are installed which are made of anti-acid metal to protect against acid waters, but this metal is so quickly worn away by the solids in suspension as to make the extra cost unwise.

A possible change of location should be carefully considered in the purchase of any pump. That is, will the pump be moved so that the length of the suction or discharge pipe will be changed or the total head be increased or diminished? How will the power available be affected? Will the same electric or water lines be used for other apparatus, and with what result?

Efficiency should always be taken into consideration, but should not be the deciding factor. This point should be carefully considered in large units and also with pumps that are to operate continuously. As some pumps are efficient when first installed, but rapidly lose their efficiency with increased wear, this point should be taken into account. Few pumps are efficient on heads of less than 10 ft. Piston pumps will show good results up to 100 or 125 ft. Centrifugal pumps vary according to design, size and service. Low head centrifugal pumps and those of small capacity will seldom show more than 40 per cent. efficiency, while many larger machines

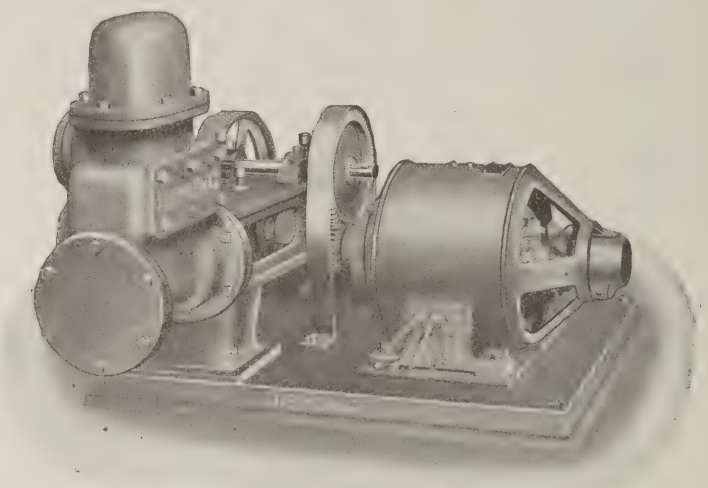


FIG. 1. A TYPICAL GATHERING PUMP

working on heads from 75 ft. and higher will show efficiencies of from 65 to 80 per cent. Plunger pumps for high heads and large capacities often show efficiencies of 85 to 90 per cent., although an assumption of 70 to 75 per cent. is safer in calculating the power required.

Service should also be given careful consideration. Will the pump selected operate satisfactorily with a minimum of attention? Are all parts easily accessible for adjustment or renewal? Can the company furnishing the pump make quick shipment of repair parts from stock, or will they have to be made up? What are the transportation facilities for new parts with least possible delay?

By gathering pumps are meant machines that take the water from the face of entries or rooms or from local dips and deliver to a central sump or basin. Pumps for this service are often used to discharge water entirely clear of the mine. As a rule piston pumps are best adapted for this work because they are light in weight, moderate in price, seldom require priming and will handle a certain percentage of air or small particles of solids. The Deming Ajax pump shown in Fig. 1 is a typical electric motor-driven gathering pump.

Small plunger pumps will often render good service where the water is bad and where the discharge pressure is high. Pumps with only a small amount of clearance will do better work where much air is taken in with the water. Centrifugal pumps are often used for this work but must be primed before starting and usually quit pumping when any air gets into the casing. They

will easily pass small solids, however, because of absence of valves of any kind.

Fig. 2 shows a typical plunger pump for gathering or use as a main pump. It is shipped with frames slotted for wheels and axles to make it portable.

To the main mine pumps much attention should be given. If the operation is extensive, requiring a number of large units, a reputable engineer should be consulted and all points mentioned above carefully considered. In general it may be said that for heads of 100 ft. or less, piston pumps usually show good results. For high heads outside packed plunger pumps should be given careful consideration. When the water is highly acidulous and the quantity small, pumps with anti-acid bronze water ends usually meet the conditions; but if the capacity is great and the pressure high, wood-lined plunger pumps will usually give best results in the long run.

On moderate heads where large capacities must be handled the centrifugal pump properly fitted and adapted to conditions will usually give splendid results. This type of pump is also usually cheapest per hundred-gallon capacity of any type of electrically driven machine.

Compressed air is frequently used for mine pumping. In some cases it is employed in a displacement pump designed for steam. This, however, is highly inefficient and not recommended. Air is often used in an air lift. In this case a pocket is drilled about 120 per cent. below the water level to give the air lift the necessary submergence. In such cases large capacities are obtained with efficiencies varying from 15 to 40 per cent.

The term "head" is often much misunderstood, but is nevertheless important, for it represents the equivalent in vertical elevation of several existing factors. For example, 100 gal. of water is to be elevated each minute 100 ft. through a given size of pipe. The static or still-water head is 100 ft. If the water has to pass through a 2-in. pipe it offers resistance equivalent to a column of water about 25 ft. high; therefore, the friction head would be 25 ft. Since the water must flow at the rate of about 10 ft. per second, and as this water must be accelerated from a state of rest to this high speed, we have an additional velocity head of nearly 2 ft., making a total head above the pump of 127 ft. To this must also be added the suction lift and the friction head in the suction line. Except in the case of large low-lift centrifugal pumps, the velocity head is usually so small as to be neglected, leaving only the static or actual difference in elevation and friction in pipe. It should be remembered that 1 lb. pressure represents an equivalent head of 2.31 ft., or 1 ft. elevation of still water exerts a pressure of 0.434 pound.

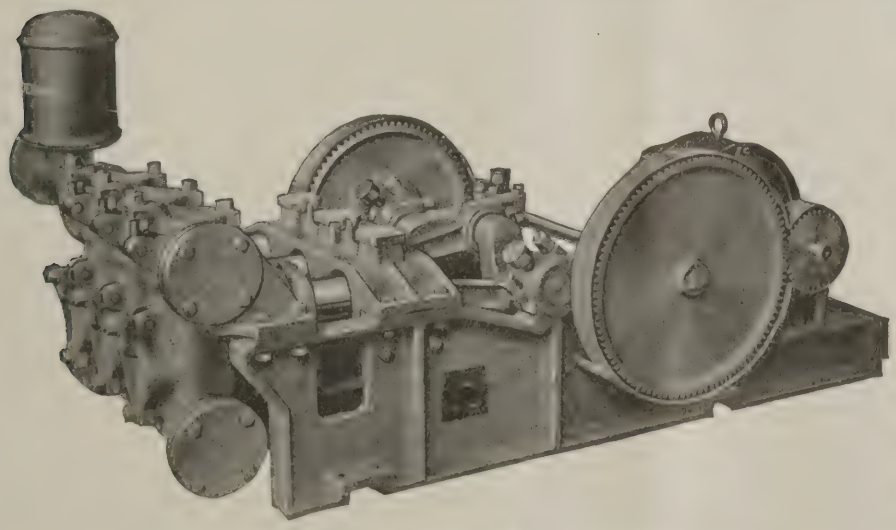

FIG. 2. TRIPLEX GATHERING OR MAIN STATION PUMP

Great care should be exercised in the selection of suction and discharge pipe for pumping units. It is a great error to install the same size of discharge pipe as the pump is fitted for. All suction and discharge pipe should be figured in each case for the service to be performed. One of the greatest errors in thought is to consider that as a larger pipe carries more weight of water, more power will be required to move it. Such reasoning neglects the fact that the velocity is correspondingly reduced, thus decreasing the friction.

In general it should be remembered that doubling the cross-sectional area of the discharge pipe decreases by one-half the velocity for the same quantity of water and lessens the friction head to one-quarter its former value. Also, doubling the amount of water means four times the friction head. The cross-sectional areas and consequent carrying capacities of pipe vary as the squares of their diameters. Thus a 3-in. pipe will carry 2¼ times as much water as a 2-in. pipe, while a 4-in. will carry 16 times as much as a 2-in. pipe. It will therefore be seen that it is usually economical to select relatively large pipe. It should also be noted that acid waters attack iron and steel much more readily at high velocities than at low ones. This also favors the larger pipe. Where an operator has an overstock of a given size of pipe, but requirements show that a larger pipe should be used, a double line can be laid so that each line will carry one-half of the total amount.

There seems to be a general feeling among pumpers that no air should be allowed to accumulate in an air chamber on a pump discharge. This is a grave error. Few types of pumps will deliver a uniform flow at the pump, and wherever the flow is not steady there will be a wide variation in pressure on the line, a consequent stress on all parts of the pump and a loss in power in operation. These may be small in some cases or result in great damage in others. Stripping of gears and breaking of connecting-rods and shafts often arise from this cause. A small petcock placed in the suction line of a piston or plunger pump and opened as often as necessary will generally supply the needed air which gradually gets away from the air chamber. If the discharge line is long an extra air chamber made up of large pipe fittings and placed about halfway to the discharge outlet will be a decided help. Air in an air chamber is to a water line what springs are to a car, or what pneumatic tires are to an automobile.

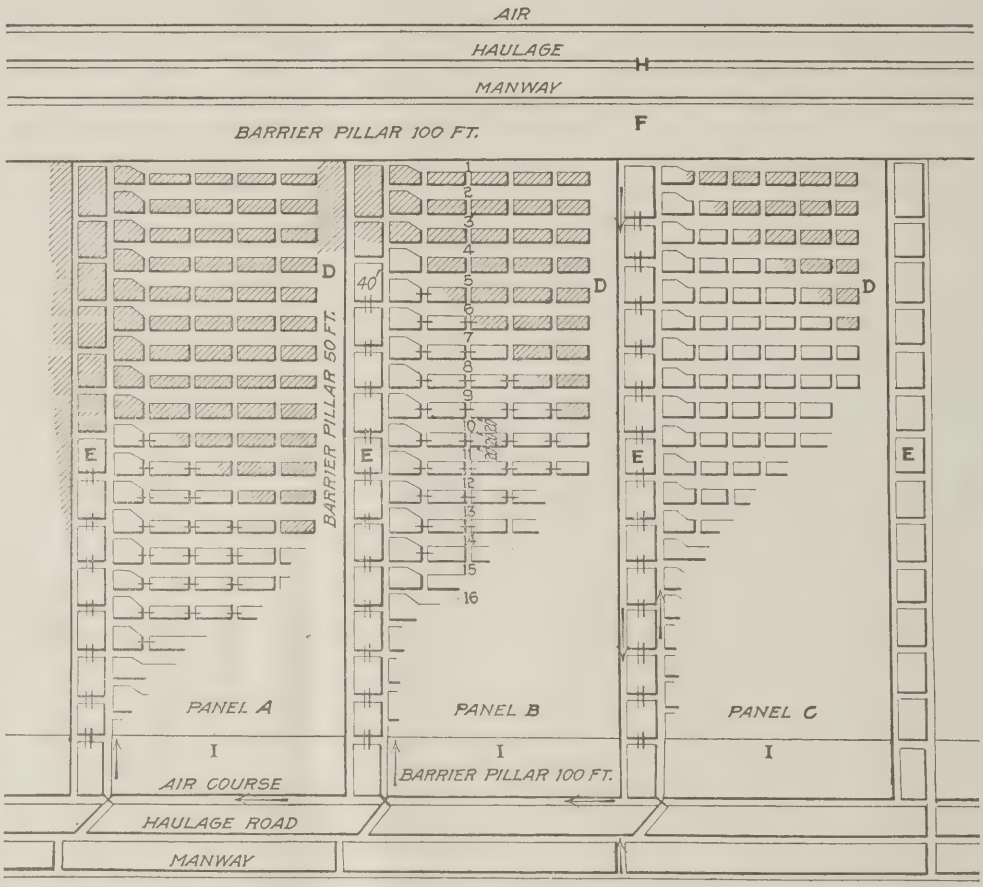
An operator is frequently called upon to do what seems to be the impossible in order to prevent loss of the mine. It is of course impossible to foresee and advise in an article of this kind for every case, and I therefore suggest only a few emergency makeshifts.

Suppose that the discharge line is so small that the friction head entails a pressure too high for the pump. If the pump is a centrifugal machine, no harm will result. If it is of the piston or plunger type, run a parallel line if possible so as to divide the discharge. If this is impossible, connect a bypass from the discharge back to the suction or waste to the ground and control with a valve. This will reduce the pressure by reducing the amount of friction head.

Suppose that the main pumps break down and only low head pumps are at hand. If centrifugal machines are available, they may be connected in series; that is, the discharge of No. 1 may be connected into the suction of No. 2, so that if each pump is good for only 50 ft. both will be good for 100 ft. If one pump is built to stand a low pressure it should preferably be placed about one-half way from the sump or other source of water supply to the point of discharge. Centrifugal pumps may also be placed in the lines of other types of pumps to help out, as they easily adapt themselves to conditions. Suppose that the discharge head becomes too great for the centrifugal pumps. This may be remedied in a manner similar to that last suggested, but if compressed air is available several small air connections may be made into the discharge line of the centrifugal pump and the inflow of air regulated by a valve in the air line. The result will be to change the density of water in the line, reducing the pressure on the pump nearly one-half; consequently, the pump will discharge against an elevation nearly double that for which it was intended.

The following general suggestions may also be appropriate: Prepare as far as possible for emergencies. Have faith in the traveling representative of the pump house with which you deal. See that pumps purchased are adapted to conditions both present and ultimate. See that total head stated includes all friction head, suction and discharge heads. Don't overstate conditions in buying centrifugal pumps, but name conditions as they exist. As centrifugal pumps must have correct speed, make sure your electric lines are large enough and that the voltage is right. Remember that coal, slate, or other solids may clog up the impeller of a high lift pump so that it may shut off the capacity almost entirely. Use your common sense liberally.

A war-saver is a life-saver.



He also serves who stays and saves.

After all, saving is not sacrificing.

Many are giving their lives; you are asked to loan your money. Buy War Savings Stamps.

Standardized System of Mining

The North Western Mining and Exchange Co., at its mines situated near Dubois, Penn., has standardized its system of mining by the adoption of the panel plan of working shown in the accompanying illustration. These panels are 1200 ft. long. The rooms are driven 300 ft. off one entry only. The 50-ft. pillar *D* is left between the ends of the room and the next butt entry *E*. The 100-ft. pillar *F* is left between the ends of the butt entry *E* and the next set of cross-entries *H*.

PANEL SYSTEM OF OPERATION ADOPTED

The 100-ft. pillar *I* is left between the cross-entry and the first room on the butt entry.

The butt entries are driven to their proper length before the rooms are turned off, after which the rooms are driven on the retreating principle. When the second room has been driven up robbing is started on the pillar between rooms Nos. 1 and 2; then, as the next room is driven up, the pillar between rooms Nos. 2 and 3 is drawn, and so on, six pillars being robbed at the same time and six rooms being driven on a butt entry at one time.

Bituminous coal will probably continue to be used under steam boilers but to a lesser extent. In the future its principal use will be in the byproduct plants because of the higher commercial value of the products that can be made from it. The higher the percentage of volatile combustible the higher will be the commercial value of the coal. The time may come when we shall consider anthracite as of minor importance as compared with the high-volatile bituminous.

The Credit of the Coal Man

By J. C. TAYLOR
Louisville, Ky.

SYNOPSIS—*Just at present the coal business, especially the portion of it in charge of distribution, can operate upon a strictly cash basis. Such operation, however, may be unwise, as a refusal of credit may seriously inconvenience a customer and cause him to seek his fuel elsewhere when present abnormal conditions have changed to those more nearly normal.*

ONE of the interesting features of the coal situation today is that of credit. At first glance there may not seem to be any question of moment involved, because the average coal man has no need to extend credit. If one man is not willing to buy coal and pay cash for it another is. Thus for the first time on record the entire coal trade, including mine owners, jobbers and retailers, is in a position to arbitrarily eliminate credit.

It is here that the danger lies. It is this that makes it a feature of the situation. The future standing of the coal trade in the public eye hinges considerably upon how this matter is handled, whether the constituent members of the trade handle it in a manner to acquit themselves creditably, or whether they regard the whole affair as a cold business proposition and proceed to collect the cash regardless of the feeling of customers and the practices that have prevailed heretofore and still prevail in most lines of business.

There are two sides to this question on which endless argument may be produced and many phases and wrangles can be developed and enlarged upon. It all boils down, however, in the final analysis to the point where the coal trade is being put on trial. Will it or will it not so conduct itself as to justify the abuse, the hard feeling and the harsh words that have already been forthcoming to the coal man from the general public?

The Present Opportunity

One way of looking at the matter is this: The coal man has now his opportunity to retaliate for past unkindnesses on the part of the public in classifying him and to allow the public to sweat and pay its bills promptly.

There is another way to look at it, however, a way that presents more appeal and promise, for the future welfare of the relations between the coal man and the public. To point out this way and make a plea for a proper extension of credit on the part of the coal trade is the purpose of this article.

The coal man, collectively speaking, needs to improve his standing in the public eye. It may be no fault of his that he has been the subject of abuse and has been wrongly classified in the public estimation. It is easily apparent, moreover, to one who is familiar with the situation that the fault in this case is more with the public than with the coal man. At the same time, while it may not be the fault of the coal man that he does not command more of the confidence and good will of the public, it is plainly the duty of the coal man to strive for a better understanding and relationship.

There is a question of sentiment involved here, and while some will argue persistently that sentiment is not business, and that business is a cold-blooded proposition, the fact remains that sentiment is and will always be the most dominant factor in business and business relations.

And now for a consideration of the question of credit upon its merits as a purely business proposition. The coal trade, like many other lines of business, has long been afflicted with the evil of too much credit, in which much of the credit was bad. There have been losses of profit in the carrying of long time accounts, and there have been losses of money through extending credits to get trade where credit should never have been extended.

Now, there has come a time and a condition in which the whole slate can be swept clean at one stroke. The credit business for the time being can be entirely eliminated and the trade can swing to the other extreme for a brief period of prosperity.

The important question is, Will this latter procedure pay in the long run?

It is not sufficient answer to this to pass it off by saying it will pay for the time being, and we can let the long run take care of itself.

The Future Is Important

A proper conception of business involves a vision of the future as well as a casting-up for the day. And in the future of the coal business, unless this question of credit is thoughtfully handled and treated in a broad-gaged way, and more liberally than the trade at present seems inclined to treat it, there will be found an invitation to competition which will sooner or later bring disaster to the trade which now seems so well intrenched that it can demand cash or refuse to do business.

It may be good advice, so far as the consumer is concerned, which is handed to the public about borrowing money to buy coal during the summer so as to be provided against the winter's needs, but there is a question if this will be good for the trade in the long run.

The extending of credit is a form of service. This and the carrying of a stock of coal on hand sufficient to supply current needs promptly, constitute an important part of the service which justifies the existence and maintenance in the community of the institution known as a retail coal yard.

It takes some capital to do this. The larger the stock carried and the heavier the credits extended the more capital is involved. This may seem like a hardship, but if it didn't take capital to engage in such a business, if a man could go into the coal trade on a shoestring, financially speaking, it would mean an

open field and so much competition that the business would be neither profitable nor inviting.

So, in a way, the necessity for capital investment is of itself a safeguard against the open field and wider competition. The logical course for the coal man, therefore, is to figure the value of the service he is rendering, including the interest on the capital invested and the credits extended and include in the price of the coal enough to insure a fair return.

It is presumed in all this, however, that the extension of credit is properly made. There is no occasion to argue for the careless extending of credit, nor in this day is there much excuse for it. Practically all the larger towns and cities have credit-rating organizations, and any diligent business man can check up and classify his customers and readily understand in the main who are deserving of credit and who are not. There is always a percentage of the trade put in the C.O.D. class, but these bad risks are entirely aside from the credit proposition in its broad sense.

Now is a good time for the average coal man to do a little thinking along the line of putting himself in the customer's place. And this applies where the coal man is a producer selling to a retailer as well as where he is a jobber or retailer selling to the individual consumer. The jobber or the retailer who is refused credit service by the producer is likely to look back to those days when the producers extended credits from early spring to late fall, and then turn and look forward to the future with a feeling of resentment in which he will conceive the idea of buying his coal from some one else.

It is pretty much the same thing with the domestic consumer to whom the retail dealer has rendered the service of carrying accounts in the past. He will resent the withdrawal of this service and the refusing of credit more bitterly than he will protest against the higher cost of coal. He recognizes the higher price as one of the inevitable results of war conditions, but he will be offended as well as inconvenienced in many instances by the curtailment of service in the refusal of credit.

The coal trade is now going through a boom period to a critical condition in the future, and much of the future welfare of the industry as a whole as well as of the individuals engaged therein will depend upon the conduct of the coal man at the present time in his handling of the question of credits.

The Money Lost Up a Chimney

The accompanying chart has been developed by the Uehling Instrument Co., 71 Broadway, New York. It is of interest and value at the present time when the coal problem is so important, for it enables anyone to quickly and closely estimate the money now being lost up almost any chimney due to low CO_2 content in the products of combustion.

To use the chart simply connect the percentage of CO_2 (shown in column C) with the money now being spent per year for coal (shown in column A), and the intersection of the connecting line with column B immediately gives the dollars passing out of the chimney in the form of heated gases.

Example: If $20,000 is spent per year for coal burned in a furnace whose average CO_2 shows 9.3 per cent., what is the approximate money lost up the chimney per year?

Solution: Connect the $20,000 (column A) with the 9.3 per cent., (column C), as indicated by the dotted line drawn across the chart, and the intersection with column B shows the approximate yearly loss to be $5000.

The object of this chart is to show that a high percentage of CO_2 is highly desirable. To be sure, even

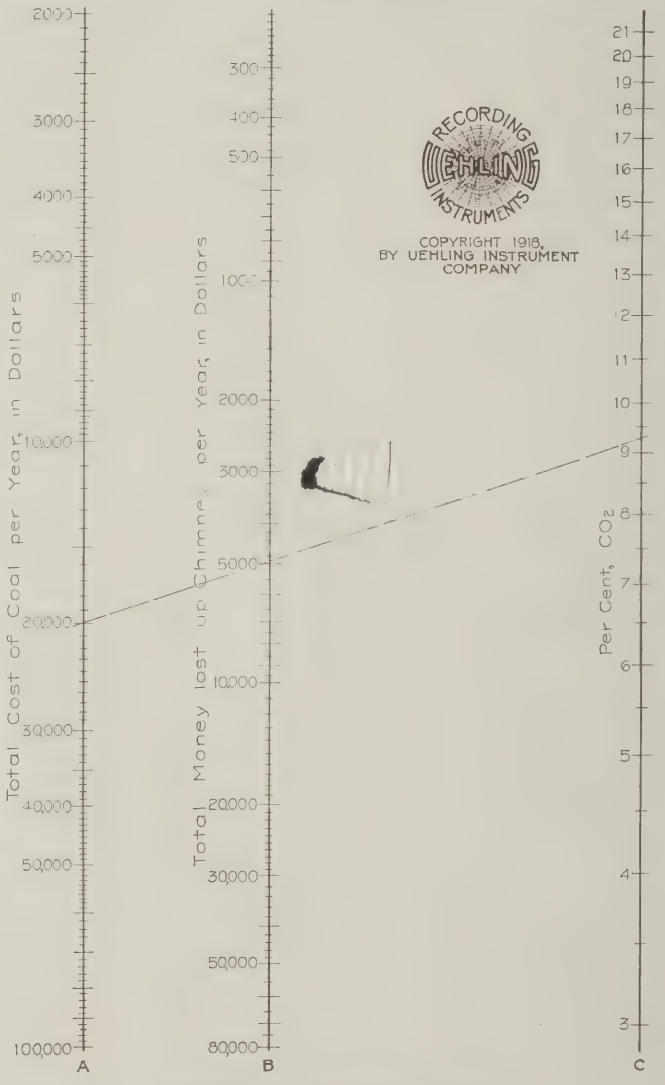


CHART OF CHIMNEY LOSSES

where the CO_2 is as high as 21 per cent., the theoretical maximum there is a loss in the average power plant because the flue gases leaving the boiler have a temperature as high as 500 or 600 deg. F. Loss, therefore, is inevitable unless a blower is used for exhausting the gases and some sort of apparatus installed for either heating the feed water or preheating the air before leading it under the grate.

This chart is based on a flue gas temperature of 600 deg. F. and an outside air temperature of 60 deg. F. Where the flue gas temperature is higher, or the outside air temperature lower, the money loss will be correspondingly increased. On the other hand, with a higher outside air temperature and a lower flue gas temperature, the money loss is proportionately decreased. Further, in the construction of this chart it has been

assumed that the coal has a calorific value of 14,500 B.t.u. per pound of combustible.

It may also be interesting to point out that where there is only 3 per cent. of CO_2 in the flue gases, 76 per cent. of the heat value of the coal passes up the chimney as waste under the conditions outlined above. It is impossible, however, for these gases to contain as low as 2 per cent. of CO_2 because this would show conditions requiring more heat than the original quantity of heat in the coal to heat the enormous surplus of air to a temperature of 600 deg. F.

Minecdotes

"Them Were the Happy Days"

Some fifteen years ago, the writer, then at a rather tender age, became "foresightman" for a surveying corps working chiefly underground in various mines near Wilkes-Barre, Penn. The transitman was an intensely energetic and rather eccentric individual named Gallagher, and known to most of his associates as "Spiker." The latter, although at that time not yet thirty, was almost as bald as the proverbial billiard ball. The years have been kind to Spiker, and in the successful mine superintendent that he has become there is little trace of the raving maniac who made life miserable for yours truly when difficulties arose in the old days.

He certainly was the limit at such times. I can hear him yet, standing with his transit set up on the gangway road, screaming and raging in a voice that used to break into a falsetto screech that was amusing to everyone but myself. "—— —— Harrigan, what *are* you doing? *Are* you doing anything, or must I come up and put that station in myself? How in —— do they expect me to get anything done with such —— —— help?" And so on continuously, for whatever length of time after his backsight was taken it might require for me to get a station point in the high roof of some pitching chamber.

Those were strenuous days, but as I look back at them nowadays lots of amusing incidents come to mind, not a few of which center around the counterattacks of firebosses who were always sent with us as guides and for our protection against possible danger. The firebosses were not directly under authority of the transitman—although expected to help out as much as possible—and without exception they disliked Gallagher for his hard driving, hard swearing ways. As a consequence they seldom failed to take advantage of any opportunity for putting something over on him, and one of the most amusing of these incidents happened in the old Black Diamond mine, on a day when we were being chaperoned, so to speak, by "Andy" Mack.

Andy was a shrewd old scout, and was always ready to take my part when Gallagher lost his temper, or demanded more than was reasonable. "For the love iv God, Gallagher," he'd say, "have ye no heart at all? Shure when ye were foresightin', ye wur so dumb we all had to take turrns doin' yer worrk, and now ye expect more of this lad than tin men could do. Yerr a wurse tyrant than old Naro iver was, a cursing and a swearing like a heathen; and you wit' nothin' but a tin cint cap between yerr bald head and the wrat' of God."

Gallagher had a way of alluding to himself in a more or less jocular manner as the "old man," offering his bald dome as evidence if anyone questioned his right to the title. On such occasions Andy would retort: "Yis, yer bald enough, all right, but it's not wit' age; its wit' rrascality."

On the particular occasion I have in mind, Andy had refused point-blank to attempt the climbing and examining of some pitching places from which the coal had been drawn out, and which stood smooth and bare, on a 35-deg. pitch, 300 ft. from the gangway road to their faces. "They're too steep, Gallagher," he said, "and they're drawn out clean, props an' all. Shure no man cud go up thim without cuttin' hitches. I'll not try it for you nor anywan else."

Gallagher became very sarcastic. "All right, Andy," he said. "All right. Give me the safety lamp then. I'll soon show you whether anyone can climb them or not. The trouble with you is that you're too old for this game and won't admit it," thereby stabbing Andy to the heart, as he well knew.

Andy handed over the safety lamp, and Gallagher, who, to give the devil his due, was game to the core, started climbing up along the rough projections of the rib. For as long as we could watch him he made very fair headway; and I took advantage of the welcome delay to go out along the gangway a few hundred yards to where our dinner buckets had been left. After refreshing myself considerably, I returned to the scene of action to find Andy sitting on the loading platform at the foot of the place Gallagher had started up, rocking and chuckling with glee.

"What's the joke, Andy?" I asked. "Listen," he replied. And I did. From far in the heights above us, a weak and evidently frightened voice was calling "Andy, Andy, Andy." It was Gallagher.

"He's shtuck," chuckled Andy. "He's shtuck, and can get nayther up nor down, and he's calling for Andy to come and get him out of his trouble. We'll lave him there a little while to think it over."

And "lave him there" we did for about fifteen minutes, which must have seemed to Gallagher like fifteen hours. Finally, with an air of great surprise, we answered his calls; secured picks and planks, and got him down safely. His hands were bleeding, and his nerve was completely gone. But he was soon back at his old tricks.

DURING A PERIOD of ten years in England, of a total number of 8683 accidents underground 5014 were due to falls of roof. The longwall system of mining is characterized by less accidents from falls of roof for the following reasons: (1) There is no second working—that is, removal of pillars of coal which hold up the roof. (2) The face is continually advancing and new unbroken roof area being exposed. (3) A gradual settling of the squeeze in rear of the advancing face. (4) Timber does not stand so long as in room and pillar, therefore less liable to decay. (5) The headings are fewer than in room-and-pillar mining.

This Record Would Put Blame Where Due

SYNOPSIS — *The operators in the Clearfield region are asked to keep an all-around record of the efficiency of their operations as producers. A miner, a foreman and a clerk are to form an efficiency committee at each of the larger mines and they will investigate the reasons for idleness and low tonnage.*

WITH the following preamble the Bulletin of the Central Pennsylvania Coal Producers' Association presents the blanks for recording efficiency that are presented below:

"In order to properly install this system it will be necessary to assign at the large collieries three men, a miner, a foreman and a clerk, and at the small units one man, who shall devote his entire time to determine the actual causes for lost tonnage including the causes of absence of employees, and to encourage the men to work full time. These men shall be known as the Efficiency Committee and shall report to the superintendent."

The first 5 columns of the first form which is known as Form M-4 is to be filled in daily by the time clerk. One set of these Forms M-4 are to be used for miners and another set for day men. All miners are to be shown on the daily list while other employees should only be listed if absent. At the close of the day's business the Form M-4 should be turned over to the Efficiency Committee which should, by personal investigation, determine the causes contributing to lost time or tonnage, and these should be entered in columns 6 and 7 of this report.

The second form is a summation of the daily Forms M-4. It is known as Form M-5. All miners are listed and all other employees who have been absent. The third form (M-6) is to be compiled from the payroll and from Form M-5. Sundays, July 4 and Christmas are not to be included as working days. For example line 2 should show 12 days for the semi-monthly period ending July 15, 1918. The following instructions are given:

The total days lost on Form M-5, Column 4, shall be extended on Form M-6, column A, line 4. The total days lost on Form M-5, column 5, shall be entered on Form M-6, column A, line 5. The total days lost on Form M-5, columns 6, 7, 8, shall be entered on Form M-6, column

DEPARTMENT OF HUMAN INTEREST

"Safety First" As Usual

Operators have somewhat divided opinions about first-aid meets. On the one hand, there is a disposition to oppose them as holiday affairs at this time, when every ton of coal is demanded by the nation at war. On the other hand, many operators feel that it is just as necessary to save life now as at any time, to the end that a large industrial death rate may not be added to the death rate on the field of battle. Saving and economy of material embrace the saving and economy of life, limb and working time, as well as of goods and chattels.

Moreover, companies which had good first-aid teams protecting the lives and limbs of their men have seen these teams dismembered by the war. The young men of whom such teams are composed have been the first to volunteer and the first to be drafted. The work has largely to be done all over again, and the enthusiasm which started the corps in the first place has to be recreated—and will have to be more than recreated; for the men who are to be drawn into the first-aid service now must perforce be those men who failed to answer to the safety-first call when it was first made.

Many also are the operators who look upon service in the first-aid team as a valuable lesson in altruism. The man who trains himself to help his fellow workman is the same man who examines himself and his daily life to find out how he can help his nation in the war. Patriotism and first-aid service go hand in hand. One stimulates the other.

The views of these operators—who will deny that they are right?—will prevail in Somerset County, and a meeting will be held at Sipe's Race Track, near Jenners, on Saturday, Sept. 7. The chairman of the executive committee is Fletcher W. Cunningham, state mine inspector, and the other members of the committee are Samuel Steinbach, of the Consolidation Coal Co.; C. F. Roy, of the MacGregor Coal Co.; M. M. Truax, of the Victor Coal Mining Co., and S. C. Halverson, of the Quemahoning Creek Coal Company.

Teams have already been entered by the companies just mentioned, and by the Brothers Valley Coal Co., of MacDonaldton; the Knickerbocker Smokeless Coal Co., of Hooversville; the Baker-Whiteley Coal Co., of the same place; the Davis Coal and Coke Co., of Boswell; the United Coal Corporation, of Jerome, and the Gibson Coal Co., near the same town. Last year 22 teams entered the field. It seems likely that this year there will be more. If possible, all the judges will be physicians; but as they are difficult to secure, expert first-aid men may have to act in that capacity. The Industrial Department of the Y. M. C. A. is still the backer of this splendid work, and if a team desires to enter application may be made, as in former years, to George B. Landis, the industrial secretary of the Y. M. C. A. at Harrisburg, Pennsylvania.

Work Will Win the War

A meeting held by the Pittsburgh Terminal Railroad and Coal Co.'s mine workers and officials illustrates the meetings being held everywhere to emphasize the truth that "Work Will Win the War." Unless we are ready to back the fighters with our services, the war cannot be won. The meeting in question was held at Bruceton, Penn.

Safety Inspector J. W. Bowles and W. E. Houston arranged a most appetizing out-of-door banquet on the lawn adjoining the Bruceton Hotel. To this dinner all the employees who had completed the first-aid training course in 1918 were invited.

After the repast talks were made on "Safety First" and "Win the War" topics by General Manager F. B. Lincoln; W. G. Duncan, senior inspector of the Associated Companies; Edward Stauffer, Pittsburgh Terminal Railroad & Coal Co., and C. D. Mason, mine safety engineer, and Leader Morey, of Pittsburgh's Four-Minute Men. The speeches were heartily applauded and the men returned confirmed in their determination to mine more and "cleaner" coal than in the past, so as to bring the successful termination of the war a little nearer.

Safety Congress To Precede Bond Issue

At the request of the United States Treasury officials expressed through Dr. Royal Meeker, of the Department of Labor, a director of the National Safety Council, the latter organization has been requested to hold its meeting no later than Sept. 20, so as to leave the safety engineers and others at liberty to boost the Fourth Liberty Loan, the sale of the bonds commencing Sept. 28 and ending on Oct. 19.

Something of this kind has long been anticipated and the date of the safety congress has consequently been in doubt, for the boosters for safety are as keen for the safety of the nation as for the safety of the individual and they desire to be on hand to sell bonds from the time the whistle ushers in the drive till the whistle blows for its close.

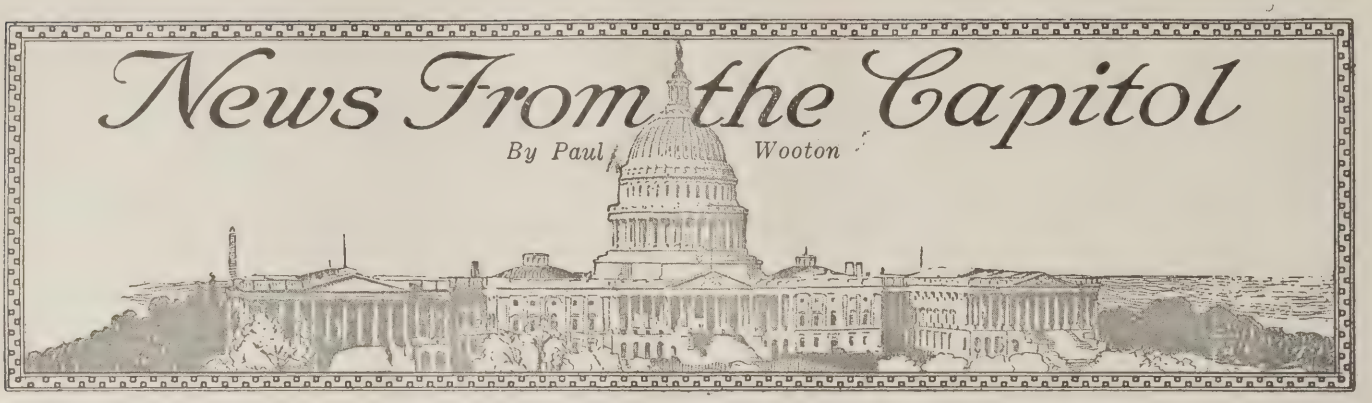
The Y. M. C. A. drive, so long postponed and so badly needed to reëstablish the funds of that organization, will follow the Liberty Loan campaign in the end of October. Consequently there is every reason why the business of the safety congress should be advanced to the dates chosen—Sept. 16 to Sept. 20, both dates inclusive. The mining sectional meetings will probably be held on Sept. 18 (Wednesday) and in the morning of Sept. 19 (Thursday). St. Louis is the place chosen for the meeting and a large attendance is expected.

The meeting will furnish an excellent opportunity for comparing notes regarding the plans to float the new Liberty Loan, which is now placed at five billions of dollars, equivalent to $125 per wage earner.

Significant Electric Locomotive Accident

John Reider, a night pumper at the Sykesville shaft of the Cascade Coal and Coke Co., Jefferson County, Pennsylvania, had an accident which illustrates the probable cause of many electric-locomotive accidents. He was engaged in running the locomotive from pump to pump, that being his mode of traveling in performing his duties as pumpman. The motor blew out a fuse, scaring him so that he attempted to jump to safety. Unfortunately his clothing caught in the motor, and he was dragged for some distance before being released. His right leg was broken in three places.

The causes of the accident are possibly two: Loose clothing and inexperience. However, it is a fact that such blowing out of fuses and short circuitings of current do sometimes and perhaps quite frequently scare or stun the locomotive engineer, causing him to leap or be thrown from his seat and fall beneath locomotive or cars. If the accident is not observed and is fatal, no one can explain its occurrence. Every provision possible against such accidents should be provided.



Dangerous To Carry Tools up Ladder

The illustration below, for which we are indebted to "The Anode," published by the Anaconda Copper Mining Co., shows the right and the wrong way of taking tools to one's working place in a heavily pitching seam. If carried up a ladder, the tools foul all the way. The man who tries vainly to hold both the tools and himself finds them slipping from his grasp without his being able to get a new purchase.

This makes him take risks which should never be taken, and, as a result, he loses his hold and falls to the level below, accompanied, or perhaps even followed, by his tools. The result is apt to be fatal. How much better to haul the tools up a boarded chute. In this way not only is the workman protected, but also the persons who may be traveling on the level. The Anaconda Copper Mining Co. provides these chutes at all stopes. The genius of a pick or saw for finding projections in a rise cannot well be exceeded. One makes a long and trying trip if one attempts to carry tools up a ladderway. For this reason chutes should be provided.

ILLUSTRATING BOTH AN UNSAFE AND A WELL-ORDERED WAY OF DELIVERING TOOLS TO THE WORKING FACE

Coal Mining Is War Work

Coal mining is classified by the Department of Labor as "wholly war work." In announcing the policy which would prevail in the control of the recruiting and distribution of unskilled labor for war production, the department defined war work as follows:

1. The manufacture of products or erection of structures directly or indirectly supplied to some department of the Government for use in connection with the war. "Indirectly supplied" includes goods delivered under subcontracts to Government contractors.
2. Coal mining is wholly war work.
3. Railroads and farms are engaged in war work to the extent that under this program they are protected from all recruiting by other industries.

Apportioning Available Coal Supply

A budgeting plan for the apportionment of the available supply of coal which has been under consideration for some time was brought a step nearer realization last week when Dr. Garfield discussed the matter at length with representatives of the Railroad Administration, the War Industries Board and the Shipping Board. It was revealed at the conference that no less than 110,000,000 tons of coal will be required to make and transport the steel necessary to meet the Government's requirements.

No More New Industries for New England

The order prohibiting the establishment of new industries in the East and in New England came too late, in the belief of several officials at the Fuel Administration. Not only must additional industries be kept out of that territory, but it is believed that a portion of those now located there must be shifted to other sections of the country. As it is there are many areas into which it is physically impossible to transport the requirements of coal in addition to handling the finished products and taking care of other essential transportation needs. Outside of these congested districts, the steam-coal situation is not bad. From the Ohio line west there are more screenings than operators know what to do with. The situation in steam sizes is particularly easy. It is believed that many industries could be transferred to the Middle West and to the South where they could be near an adequate coal supply. If this were done, the problem of distributing coal would be simplified considerably and industrial efficiency increased, it is believed.

A Shortage of West Virginia Coal

Demand for high-grade West Virginia coal is outstripping production so decidedly that the situation was the subject of a conference last week between West Virginia operators and J. D. A. Morrow, who is in charge of distribution for the Fuel Administration. Additional coal is needed urgently for Lake shipment, for byproduct use and at tidewater. Various means for stimulating production in West Virginia are under consideration.

Storage Conditions Unequal

Great inequality exists throughout the country as to the amount of coal held in storage by consumers. This is shown by the returns to the Fuel Administration from the recent questionnaires sent to consumers. The storage is to be equalized as much as is possible. There is no idea of taking away any of the coal accumulated by a consumer, provided, of course, it does not amount to hoarding. When a reasonable reserve has been secured, a greater accumulation will not be allowed so that others may be given an opportunity to get their share of coal for storage.

Returns are coming in from the consumers' questionnaire at the average rate. Three-fourths of the consumers in New England already have made returns. A considerable number of large consumers, however, have not responded. It is believed that this is due to the fact that the matter did not come to the attention of the proper official. A little prodding may be necessary, but as a rule, the large concerns are not the ones which delay statistical compilations based on replies to questionnaires. A number of men are on the road examining the veracity of the returns. Every effort will be made to make examples of those making erroneous reports. The complete program which it is hoped will result in the stimulation of coal production is now before the President. Pending his approval, the details of the plan are not available.

Better Prices at Pittsburgh Wagon Mines

The local fuel administration at Pittsburgh, Penn., on July 30 prescribed new prices for the wagon and truck coal mines of that district and certain rules governing the operation of such mines.

First—For coal not moving by rail, a manufacturer or large consumer who makes a blanket contract with a wagon mine for the entire daily output of any one or more of these mines, delivery to take place each day of

the week as the coal is produced, the maximum price shall be $2.45 per net ton, f.o.b. mine platform.

Second—For all coal so purchased in large quantities for public institutions, hospitals, office buildings, large apartments, small manufacturing operations, mercantile establishments, and like institutions, including a supply to retail coal dealers, the maximum price (where not taking the full and complete output of the mine and providing for its continuous operations without interruption) shall be $2.75 per net ton, f.o.b. mine platform.

Third—For those consumers of coal, ordinarily covered by the term "domestic users" and taking only small quantities, and especially any consumers not in the first and second classes above mentioned, the maximum price shall be $3 per net ton, f.o.b. mine platform.

Hauling rates based on the delivery of coal to stock piles, or to the street, or curb, and not including the handling of it in any way, have been fixed as follows:

First mile or part thereof	$0.70
Over 1, up to and including 2	.80
Over 2, up to and including 3	.95
Over 3, up to and including 4	1.15
Over 4, up to and including 5	1.30
Over 5, up to and including 6	1.50
Over 6, up to and including 7	1.85
Over 7, up to and including 8	2.15

The rates arrived at by the administration were determined after many conferences with representative bodies, such as the executive committee of the Pittsburgh Truck Mine Coal Producers' Association, a committee representing those purchasing coal from wagon mines, and a committee representing the manufacturers of trucks.

The prices are to be in effect from Aug. 1 to Nov. 1, and the prices apply to screened coal. The hauling rate is based on the loaded mile. For example, a six-mile round trip from the mine will be charged at the three-mile loaded rate. The prices apply only to clean coal, and should dirty coal be delivered 50 cents less per ton should be charged.

Restrictions on Anthracite from Lake Docks

Anthracite coal may be shipped from Lake docks to the following sections only:

1. The states of North Dakota, South Dakota, Minnesota and Wisconsin.
2. The upper peninsula of the State of Michigan.
3. That portion of the State of Iowa located on the north of a line coincident with the Illinois Central R.R. from Dubuque to Sioux City, Iowa.
4. The following-named counties within the State of Illinois: Cook, Stephenson, Winnebago, Boone, McHenry, Lake, Ogle, Dekalb, Kane, Dupage, Lee, Kendall and Will.

An order to this effect has been issued by the Fuel Administration, which carries into effect the plan formed several months ago to restrict the use of anthracite in distant regions. It also is impossible from a transportation standpoint to provide the East with any other fuel for domestic purposes.

In order to provide a fuel adapted for use in base burner stoves, in the districts from which anthracite has been cut off, regulations and prices have been issued for sized screening.

For all special sizes passing over a mesh over ½ in. in size the mine price for prepared coal is allowed. For special sizes passing over ¼ in. and under ½ in. in size, the mine price for run of mine coal is allowed.

For all fine sizes passing through a mesh ½ in. or smaller, the price fixed is 30c. per net ton less than the prevailing price for standard screenings. If fine screenings or "carbon" passing through ½ in. or smaller mesh as the result of producing special sized screenings are mixed with other coal, the selling price shall not exceed the applicable government price less 30 cents per net ton.

Tests on an Odor Warning

A series of tests with stenches as a warning for miners is being made by the Bureau of Mines. A liquid chemical is injected into the compressed-air line at the engine room. The vapor thus is carried quickly to the farthest opening of the line. About five minutes are required for the warning to be received at a punching machine which is approximately 1800 ft. from the compressor. The odor soon diffuses to all near-by parts of the mine, and is carried along by the ventilating current. The laboratory work in this connection is being done in the gas section under the direction of Lieutenant Katz. The most disagreeable nontoxic odors obtainable are being tried.

Brief Washington Notes

Coke prices in Pike County, Kentucky, have been announced as follows: Blast furnace, $6.50; 72-hour selected foundry, $7.50. The prices do not apply to coke made at the plant of the Marrowbone Mining Co.

A price for modified mine-run has been established in Barton and Vernon Counties, Mo., and in Cherokee and Crawford Counties, Kansas. The price is: Nut-run, or stoker coal, $3.05 per ton; mill coal, $2.95 per ton.

Contracts now may cover a longer period than one year. A ruling to this effect was issued last week by the Fuel Administrator. Any extension beyond one year, however, must be approved specifically by the Fuel Administration. If such approval is granted, contracts may be entered into without a limitation or with a limit in excess of one year.

Bituminous coal production during the week ended July 27 totalled 12,802,000 tons. This is a decrease of 121,000 tons over the week preceding, but is an increase of 13 per cent. over production during the corresponding week of last year. Anthracite shipments increased slightly. Forwardings during the week under review were 40,942 cars.

G. C. Foedisch, of Philadelphia, Allen C. Dodson, of Bethlehem, and Julian B. Huff, of Greensburg, Penn., have been selected by James B. Neale as members of a committee to assist him in the effort he is making to increase coal production.

F. W. Guthrie, president of the United States Coal Corporation of Pittsburgh, set 200,000 tons as the goal of production he wished his men to attain in July. He urged them to "go over the top" for that unprecedented production in the company's mines. Mr. Guthrie has advised James B. Neale, the director of production, that the month's production apparently was 210,000 tons.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The disheartening reduction in bituminous coal output still continues, though the fall in tonnage is less than last year. In the week ending July 20 the output of bituminous coal was 363,000 short tons less than in the week before, and in the week ended July 27 it was 121,000 tons less than in the week ended July 20. The tonnage has declined therefore to a point 484,000 tons a week or 80,000 tons a day below the record week ended July 13.

The car shortage has much to do with this condition, but it must be remembered that if in any section the coal industry is itself to blame and in that same section the railroad industry is blameless it will not serve any good purpose to show the railroad industry to blame elsewhere. It is the hope of our industry to show that the railroad industry is always, everywhere and in all cases, to blame except perhaps in the anthracite region.

As stated, however, the railroads were principally at fault. The car-shortage percentage was 3.9 in the week ended June 20; and it was 5.1 in the week ended June 27. On the other hand the labor shortage including strikes rose only from 4.2 to 4.4 per cent., but with a declining car supply surely it should not have increased at all.

The car shortage increased in Illinois, Indiana, markedly in southern Ohio, in Westmoreland County, Pennsylvania, in central Pennsylvania and in Somerset County of that same state; it increased lamentably in the Fairmont region of West Virginia (from 8.8 to 19.3 per cent.) and in the Cumberland and Piedmont district only less lamentably. The Hazard field in Kentucky received less cars, so did the northeastern and western Kentucky fields. The southern Appalachian area saw its car shortage increase from 7.6 to 16.3 per cent. Southwest Virginia suffered somewhat more than before; so did Kansas and Missouri; Oklahoma and Arkansas and so also did Iowa. Even the Rocky Mountain area had less cars.

Some sections showed a trifling improvement as might be expected. In all, there were four of them. Northern and central Pennsylvania which is grouped as one, western Pennsylvania, the New River and Winding Gulf region, also grouped as one, and the high volatile region of southern West Virginia. The railroads are doing less well than before. It will now pay to store coal, especially slack.

The attitude of Provost Marshal General Enoch H. Crowder is rapidly getting more and more favorable to the giving of miners deferred classification. Perhaps we shall ultimately arrive at the point that we shall not summon men at all to service whom we do not want to serve. We shall not ask them to come to the draft boards to make their excuses. We shall not demand that they give reasons why they should not do what they so much want to do and what we do not want to them to do at all. But Crowder is not making the laws. If he will only continue to advise mine workers to make pleas for exemption and will continue to favor the placing of mine workers on the deferred list no one can file objection to the fact that he does not subvert the civil authority by setting up laws of his own writing and devising.

Though James B. Neale, director of production of the Fuel Administration, is not succeeding wholly to the liking of the insistent public he is doing much to maintain and increase tonnage. He has chosen as a production committee: G. C. Foedisch of Philadelphia, Alan C. Dodson, of Bethlehem, Penn., and Julian B. Huff of Greensburg. He is endeavoring to induce the mine workers to give up their holidays, fairs, picnics and other festivities. It is pleasing to note how successful has been his work in this direction.

Barnesboro, Penn., is a near neighbor to Spangler whose renunciation *Coal Age* recorded the week before last on page 180 when Spangler gave up the Firemen's Convention. At this town of Barnesboro an annual picnic was to be given by the Northern Cambria Scottish Club. A protest from James B. Neale brought about a cancellation of the event. The Scots remained loyal to the spirit for which America went to war, and there are other like abstentions from merriment, all on behalf of that great cause in the support of which our mine workers are engaged almost more importantly than any other civil workers.

In the Somerset county region the mine workers have greatly figured on the Meyersdale meet of the Western Pennsylvania Firemen's Association, Aug. 12-18. The people at Meyersdale and the vicinity want the event held as scheduled and to this end S. A. Kendall left for Washington to assure the Washington authorities that the mine workers had been working overtime that they might earn the right to attend, that they would put out 100 per cent. production while the fair was in progress and would try to induce all the miners of the region to sign formal pledges binding them to do their utmost to produce a maximum tonnage. But what sort of maximum tonnage is it that is produced by men who go fairing when the mines should be working?

In Alabama, where formerly slackness ruled, the mine workers are doing admirably. In Walker and Winston counties in the Warrior River Basin, they are beginning to give 49 hours to their work, working 9 hours for the first 5 days and 4 hours on Saturday. What is more the quality of the coal is much improved.

The temperance question, as always, is one of the most important of all questions and one of the most dangerous to approach. Seward E. Button, chief of the Department of Mines has succeeded in drawing the fire of the union by his remarks on the intemperance of miners. He does not appear to have said anything amiss. Doubtless someone in authority needed to say what he has said. "It must needs be that offenses come, but woe unto him by whom the offense cometh," and the name of that man is Button. His statement will do a great deal of good—but not to him.

Frank J. Hayes has attacked him somewhat childishly. Some miners certainly do drink to excess. No one can deny it, and if there were only one miner who so drank

Men of draft age employed in the coal mines will best serve their country by remaining where their experience and skill will assist in maintaining and increasing the production of the fuel with which the munitions and supplies are manufactured, and by which the locomotives and ships are propelled. It is not only the right of such men to continue in their present employment, but it is their patriotic duty to remain at their posts, and local and district boards have been instructed by the provost marshal general to impress this fact upon the men employed in the mines who come before them for registration. It is just as much the duty of such a man to remain at his post in acceptance of the action of his local or district board in placing him in a deferred class as it is for a man in uniform to obey the orders of his commanding officer.—Provost Marshal General Crowder.

the tonnage would be reduced. President Hayes is reported to have said that he could prove by figures provided by prohibition statisticians that less beer is consumed at present in the coal-region towns than at any time within the past quarter century. If that is true, then it only shows a reduction in intemperance, not its abolition.

President Hayes also declared that the statement of Chief Button that anthracite production had been reduced through intemperate habits of miners was the basest and most deliberate insult he had ever heard as coming from a state official. He pointed to the fact that with 35,000 men less in the anthracite field than during the same period 16 months ago, production had been increased.

All this is extremely interesting, but if the tonnage is to be maintained and increased the intemperate men must all be made to mend their way. It is of no use to try to clear the reputation of the industry as a whole; it is of no use to try to show that the ship workers are more intemperate. The question is, are there or are there not men in the industry who lose time owing to drunkenness?

Few or Many, Those There Are Reduce Tonnage

If some of the Lehigh Valley Coal Co.'s men had been alleged not to have done their duty in the purchase of Liberty Bonds would it have been an answer to show how much the generality had done? The mine workers of the Lehigh Valley Coal Co. evidently thought not, for they made every man take out his bond. If they would only duck the men who booze so much that they cannot, or do not care to, work and do it just as thoroughly and industriously as they ducked those who would not buy bonds the mines would be full and the saloons deserted. We commend this thought to them.

The way to honor is not by making protests and threats against the useful gossip but by reformation. Let the miners compel the booze slackers to be temperate, and there will be an end of criticism. Then if Seward E. Button and his inspectors permit bad air and unsafe conditions, as Messrs. Hayes, Matthews and the board of District No. 9 assert, there will be a good opportunity to push the case against them.

On Aug. 2 the director of production announced his plan for a production manager in each producing district and at each mine a committee of six—three representing the mine workers and three the operators. These committees will be selected for the purpose of stimulating patriotism and arranging for local meetings at which the need for increased production will be brought home to the men.

Draft Board Assaulted for Active Exemption

The Schuylkill County miners in the anthracite region are angry with the district draft board at Shenandoah for trying to force exemption on them. A number appeared on July 22 ready to go to Camp Lee. These men refused to accept exemption and one of them knocked down Chairman Ditchey when he insisted, while another upset a policeman who tried to prevent him boarding the train. Others climbed through the car windows while still others left in automobiles for Mahanoy Plane, where they caught and boarded the train.

It has been decided, it is said, that the "coal and iron" police who guard the mines against fire, theft and pro-German violence come under the rule "Work or Fight." Many of the patrolmen are ex-regular army men and almost all are within the draft age. The coal operators of the Lehigh field are instituting an inquiry to see if these highly-essential men are, by a mere technicality, to be compelled to enter other employment.

It is said that at one of the Lehigh Valley Coal Co.'s operations the men have refused to work with any man accepting exemption. Coal company officials at Shamokin, Penn., went before the board and made an appeal to the patriotism of the board members, declaring that their failure to hold back the mine employees would seriously impair coal production at the local collieries. At a meeting of the selective-service men the board put the issue squarely up to the men themselves, declaring a willingness to exempt all those who chose to stay at their employment in the mines or who felt that they were actually needed. Not one of the 15 coal mine workers who were drafted elected to continue at their mining work and the board accordingly certified them into the service.

The breaker boys of the Pond Creek colliery of the East Point Coal Co. struck Aug. 1 for more pay, and the carpenters and outside laborers took their places at the pickers and chutes and kept up the production.

The mine workers of the Ninth District, which includes Shamokin, Lykens, Pottsville and the Panther Valley, have been threatening to demand a 100 per cent. increase in wage and the check-off, with the wage increase to date from Apr. 7 of this year. They also say that this advance can be given without an increase in the price of coal. This would involve paying back wages to the extent of $3,000,000 up to Aug. 1. It is a most preposterous demand, of course, and could not be made by men with any knowledge of conditions or any good judgment.

Secretary of War Newton D. Baker has shown his appreciation of the 150 mine workers in Mercer County who have returned to work in their declining years after having retired from the mines. Mr. Baker in his letter to H. A. Garfield says: "This is the spirit which free and liberal government always engenders and which insures the triumphs of our arms and aims. I should like, through you, to send a personal greeting to these heroes of the pick."

English Little Spoken in Central Pennsylvania

In the central Pennsylvania field it has been ascertained for the Fuel Administration that 29,000 men speak English, 10,200 Italian, 10,000 Slavish, 7500 Polish, 4000 Magyar, 2100 Russian and 7000 various other languages.

In Illinois Frank Farrington, the president of the union in that state, has strongly condemned the bonus system. He says that "trouble is brewing in the mine fields, and selfish mine owners and operators, and not the miners, are stirring it up." Some operators are trying to induce the men to change their working places in return for premium payments of various kinds.

In Ohio, 30 hoisting engineers employed by the Ohio Collieries Co. in Athens County struck on July 25. Governor Cox opened negotiations with them and on July 26 they went back to work, the wage question to be submitted to the Labor Board of the Fuel Administration at Washington. Thus 1000 mine workers producing about 4000 tons per day were enabled to go to work.

Strike Against Paying Uncle Sam a Penny a Day

In the Saginaw (Mich.) field nine mines were idle on July 23, despite orders directing them to return, one from the Federal Fuel Administrator and one from the mine district board. Some men appeared at the railway stations ready to go to work; some merely appeared as spectators; others came to keep the men from going to work. The upshot was that the "miners' train" was emptied and no work was done. The miners want 10c. a ton increase. They have never been satisfied with the so-called Washington agreement. The 10 per cent. increase in the commutation fare has made the miners still more insistent, though it is an insignificant trifle per day and it is still less as figured per ton mined. The five largest mines in Bay County were idle on July 23. Here the rise in the commutation fare deprives them of 1c. per day. These hard-fisted slackers cannot stand to pay this cent per day to the United States Government, but they are ready to vote millions and billions per annum from the pockets of their employers.

James Lord, president of the mining department of the American Federation of Labor, has been appointed head of a special section of the Federal Employment Service in charge of recruiting and supplying labor for mines. He will coöperate with the Fuel Administration, the National Coal Association and the United Mine Workers of America.

The domestic coal mines of the North Alberta district, Canada, have been running slow for some time and on Wednesday, July 24, the Bush mine near Edmonton was shut down and again on July 26. The Humberstone mine which has been producing 550 to 600 tons a day out of a total capacity of 1000 tons shut down for a week owing to shortage of orders.

Selective Service Act Not To Blame

The statistics gathered by Provost Marshal General Crowder are regarded as proving that the scarcity of mine workers in the coal-producing districts is not attributable to the selective-service law. Slightly more than 2 per cent. of the total number of coal miners in the United States have been inducted into military service.

General Crowder's figures show that there are 706,012 coal-mine operatives in the United States. Of this number only 177,502 are subject in any way to the selective-service law. This is approximately 25 per cent. of the entire number of coal-mine workers. Of this latter number, however, 130,749 or 73 per cent. already are in a deferred class. Only 6.5 per cent. of the coal workers of the country are in Class 1. The total number of coal miners in Class 1 is 46,253, or 26 per cent. of the men subject to the draft. From investigations which have been conducted by the provost marshal general and by the coal-mine operators themselves, it is said to be evident that it is the higher wage obtainable in other industries which has caused the exodus from the mines.

The draft machinery is said to be functioning perfectly. The local boards in the coal-mining regions have been liberal in the granting of deferred classification to miners. A condition, however, which cannot be met by the provost marshal general is the refusal of many miners to accept deferred classification. When put in a deferred class, many of the coal miners quit their jobs.

"Have Got to Get Where I Can Kill a German"

It was evident in many coal-mining districts, according to reports reaching General Crowder's office, that the men have not been convinced that they are striking more powerfully at Germany by staying in the mines than by getting on the firing line. "I have got to get where I can kill a German," or something to that effect, is a remark frequently heard when coal miners are urged to accept deferred classification.

General Crowder and his staff cannot well be expected to make a law of their own. All they can do is to administer the law as provided. General Crowder cannot undertake to educate the mine workers of the country to the point where they will realize that it is their duty to the country to continue in their regular line of work. This, it is believed, should be undertaken by the coal-mine operators and by the leaders among the men.

Miners Always Have Been First in the Fight

General Crowder himself called the attention of the correspondent of *Coal Age* to the military record of the coal-producing districts in the Civil and the Spanish-American wars. The spirit of the populace in these districts, he said, is such as to make it extremely difficult to interest the men in duties away from the front-line trenches. The task of persuading these men to continue their peace-time pursuits with the Huns shedding American blood is one which General Crowder feels must devolve upon someone else. He is anxious that Class 1 be cleared of the few bona fide coal miners, who are thus classified, but he thinks someone else should undertake to persuade the miners to accept the deferred classification which he is ready to give them.

The effect of the draft on the coal mining industry was discussed last week at a conference between James B. Neale, the director of production, and representatives of a number of producing districts.

The conference was addressed by Col. Roscoe Conklin of the provost marshal general's staff, who explained the attitude of the United States Government in regard to the drafting of coal-mine workers.

It was stated by those familiar with labor conditions in the mining districts that there was a disposition on the part of some mine workers to regard those of their comrades who obtained deferred classifications as slackers. Director of Production Neale declared that it should be most thoroughly understood that the Government and th United States Fuel Administration regards the man who remains at the mine doing his work, increasing the production of coal, as serving his country quite as truly and bravely as if he were on the firing line in France.

Reports from the most prominent coal-mining districts in the country were to the effect that everywhere the coal operators are exhibiting and the mine workers are displaying the most patriotic earnestness in trying to increase the production of coal. Voluntarily they are giving up many of their cherished recreations and are sacrificing their holidays. It was reported from the Connellsville district, for instance, that the men who voluntarily worked on July 4, turned out enough coke on that day to build 20 steel ships.

Production Director Neale explained fully the details of the proposed production campaign, with its appointment of production committees in every mine and the steps that are to be taken to insure full hours of labor each day and six full days a week.

Bonus Nuisance To Be Ended

Not only in central Pennsylvania is the bonus nuisance found to be undesirable. The Pittsburgh district has long ago taken action against it. Only on July 15 the Jackson district in Ohio, through the Jackson District Coal Association, decided by unanimous vote that bonuses must end. The resolution, however, did not use the word "bonus" except in the title, where it is termed the "Resolution Abolishing Bonuses." The resolution describes the offenses merely as "violations by operators. . . . of the Washington agreement entered into between operators and miners of the Central Competitive Field, Oct. 6, 1917, at Washington, D. C." The resolution requests that the Fuel Administration "order such mines, as are violating said agreement, closed down as being too expensive to operate longer under the wage rates and conditions contained in such Washington agreement."

Although the payment of bonuses to miners to hold them or to get them away from other mines is believed to be less general than formerly in the Illinois fields, charges were made at a meeting of the Southern Illinois Mine Superintendents' Association at Duquoin, Ill., a few weeks ago that certain operators are paying their men a cash premium to keep them from going to other mines. Evan D. John, of Springfield, Director of the State Department of Mines and Minerals, and State Inspector Henry Bannister, of Herrin, were among the speakers. Mr. John urged a more vigorous enforcement of laws pertaining to labor.

H. A. Garfield in an interdict on bonuses issued Aug. 5 said: "I hereby announce that if any operator hereafter undertakes to pay a bonus in any form in violation of the terms or spirit of the agreements . . . I shall assume that the mine price of coal allowed the operator is too high and I shall accordingly order reduction thereof."

Will Not Wait on Law To Act

"Loyalists" among Illinois coal miners continue to take the law into their own hands. William Knauel, a miner of Staunton, Ill., was tarred and feathered a few days ago by an "Americanization" mob after his wife complained that he had torn down and destroyed a service flag she had placed in their home in honor of her son, Knauel's stepson. After the man had been given a coat of tar and feathers, he was run out of town and ordered not to return. Staunton was one of the first Illinois communities to adopt tar and feathers as Americanization arguments.

Germany is still asking questions about the lynching of Robert Paul Prager, German enemy alien, at Collinsville, Ill. Circuit Clerk Mellon of Madison County has received a communication from Henry Nussle, Swiss Consul at Chicago, in charge of German interests in Illinois, asking for a statement of the exact facts in the case. Prager was lynched after a controversy with coal miners of Maryville, Ill., who refused his application for membership in the union and accused him of being a German spy.

Foreign Coal Trade After the War

NEW ELEMENTS will enter into the coal trade after the war and are quite likely to make it possible for us to ship our coal to Europe. The principal element will be the lessened wheat export. Great Britain is learning to feed herself. Before the war she furnished food for 11 weeks in the year, now she supplies enough for 40 weeks. It is easy to see therefore that we shall be likely to ship her less food than we have hitherto, and, that being so, the bottoms that formerly took wheat will probably go to Europe with coal.

We used to be somewhat heavily in Great Britain's debt; we now are Europe's creditor. The interest on that debt will make it necessary for her to ship us of her substance. Consequently there should be outbound empty bottoms crossing the Atlantic and these we may, presumably, fill with coal. Of course, we shall not ship this fuel to Great Britain, but we shall probably supply many of her former customers.

However, it is never safe to prophesy. Many changes have been brought by the war and as many may result from peace. Probably an attempt will be made to keep in wheat all the British acres that have been tilled during the war. Yet there will be many who will not wish to keep ancestral parks under the plough. Besides where will the men be found if Great Britain is to keep her many new factories working as well as her acres of farm land? She will not long approve of the use of female workers for strenuous, uncleanly labor; of this we may be sure. Certainly she will be opposed to long hours of work. The little amenities of civilization—flunkyism and personal service—will work their way back despite the growth of democracy and even despite the growing distaste for such occupations.

The workers also will once again advocate their doctrine that the less work everyone does the more work there is for all. Their old restrictive trade practices will resume their unhealthy growth. The spirit of the past will rise again. The plants will be more modern and progressive, but the men in them will seek as ever to reduce efficiency, arguing that the efficiency of the worker has ever been his undoing.

England may be merry England once again; that is, it will tend to seek merriment first and business afterward, a procedure which does not make for much real merriment for the workingman. He is merriest and happiest when he works a busy eight-hour day and seeks to attain a maximum product in that time. Unfortunately the war has not convinced him that his theories are wrong. The genius of his race is against him. John Bull will go back to his easy-going, benevolent way of doing business and some forms of industry will suffer for lack of sufficient labor to keep all the industries going.

Will Great Britain then have the power to be a manufacturing and a wheat-growing nation in face of competition from a regenerated Turkey-in-Asia, Russia and Mesopotamia? Probably not. It seems more likely that manufacturing and agriculture cannot both survive and that manufacturing will again win out. Should conditions allow agriculture to retain its present place among British industries, then the coal trade of America will be able to fill the ship bottoms that the farmers of America no longer use.

Coke Region Precedents Broken; Some Still To Be Broken

THE Connellsville coke region is making some new precedents these days with a fine disregard of time-honored customs. It also indulges the hope that it may be able to make still other changes in the established order. It is not to be inferred from these statements that the producers of beehive coke have been set hard and fast against innovations, improvements and other evidences of progress, for quite the contrary has been the rule, faith and practice. Few industries have been quicker to adopt new devices of proven utility or more constant in its search for better methods. It is merely to be noted that the region, always safely conservative, has been doing things which aforetime were accounted as apparently impossible. Similarly, events that were seemingly improbable of happening have been coming to pass. On the other hand, others appear almost as remote in their realization as ever.

Thus, as is noted elsewhere in these columns, when the W. J. Rainey interests, one of the leading independent merchant producers of beehive coke, formed a business alliance with a maker of steel to jointly build and operate a byproduct coke plant, one of those things happened which but a few years ago would have been considered most unlikely. That this union of interest is now regarded as a prudent and forward-looking venture shows the changes time and new conditions have wrought in an industry one time hedged about by perhaps more than the usual number of conventionalities, and certainly by some of unusual character.

Interesting as this incident is in its significance and relation to the future development of the whole coking industry, there occurred during the week of July 4 another history-breaking episode. For the present, this is important as an illustration of one of the many transformations war can bring about in the sentiment and attitude of men who are several degrees removed from the man behind the gun but who are, like him, susceptible to influences that stir to patriotism though the sentiment is expressed in a different form.

During the 37 years the Connellsville region has been identified with the production of beehive coke, the Fourth of July has been regularly, but never exactly religiously, observed as a holiday. True, there have

been years when a greater or less number of plants, under the stimulus of high prices and an active market, have worked a "short day," but not until this year of the Great War has the general order been given and obeyed to make a "full run" on Independence Day. Thus has a new precedent been established that is somewhat more than a precedent. It is concrete evidence of the fact that the workers of the region can change the old order when they will; it is tangible proof of the value of a campaign of education when stimulated by patriotism and directed by a variety of forces working with one end in view.

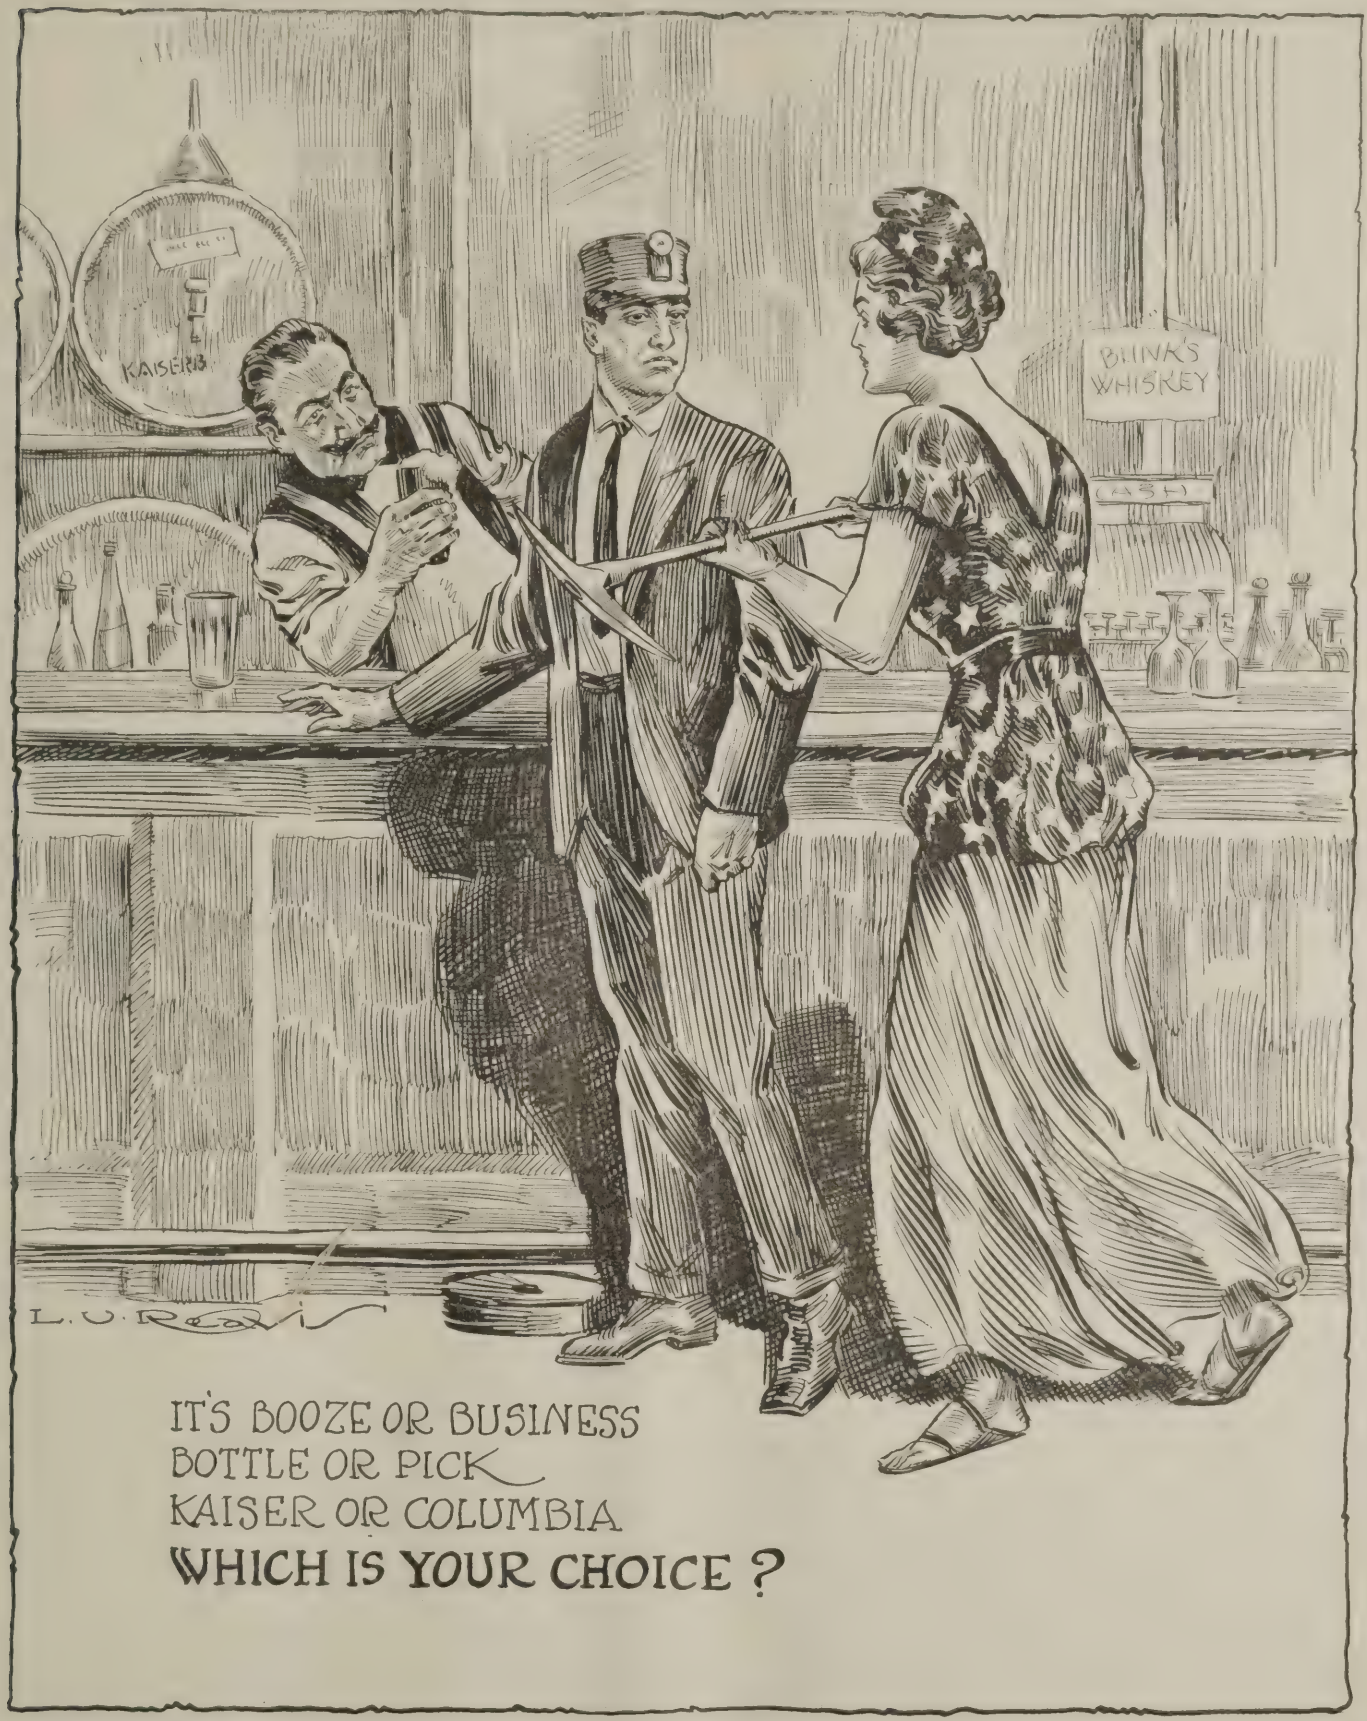
A year ago, when the suggestion was made to run on the Fourth of July, it met with so chilling a reception that its impracticability immediately became evident. The temper and spirit of the men was such that they would have very determinedly resisted any attempt to change their habits of work on our Natal Day. They were receiving the highest wages ever paid in the history of the industry, and their earnings were limited only by their efforts and their application. They were making "big money" and spending it freely, and were totally indifferent to any appeal savoring of a hint to restrain their propensity for laying-off work upon the slightest pretext. "Me plenty money; plenty beer; me no work!" was the expressive, sometimes insolent, but always conclusive rejoinder to the urgent request to be on the job next day.

During the intervening months there has been a noticeable change in mental attitude, even though the change has not embraced the habits of work in an all-inclusive and permanent reformation. Wages have meantime been twice advanced and earnings have swelled pay envelopes to the bursting point. Measured by personal necessities, there is less incentive for men to put forth unusual or long-continued effort to maintain output to the individual standard, if not increase it. Hence, to break precedent by working on a day which long-established custom has set aside as a day for the suspension of activity, indicates that some strong impelling force has moved the workmen to this action. Persistent, patient and long-continued efforts and the employment of every known persuasive means have failed, and are still failing, to induce the practice of greater industry and more regular habits of work on ordinary days. The conclusion seems to be that, having acquired a better appreciation of the situation and the significance of Independence Day than has generally been credited them, the appeal of patriotism was potent in moving the coke workers to respond to the call to pull and fork coke on the Glorious Fourth.

The Liberty Loan, Red Cross, Y. M. C. A., K. of C. and War Savings Stamp drives, the departure of draftees, the dedication of service flags and activities immediately associated with the coke region's part in the war, have given the men a better comprehension of the war situation, but they still lacked the understanding contact to impel them to industry. The money-raising campaigns excited a spirit of friendly rivalry between plants or teams and quickened the sporting blood more than they deeply stirred patriotism. The patriotic meetings, addresses by war veterans, Four-Minute Men and others were informing to the superintendents, foremen and other English-speaking men, but the influences were slow to reach the foreign-born. When, therefore, preparation for making the Fourth a workday were made, every man on the job was seen and, no matter what language he spoke, he was fully informed of the object and purpose. He not only learned what his fellow workers were going to do, and why, but he was enabled to definitely make up his own mind as to the obligation resting upon him. The response came with a unanimity that was surprising.

The success of the Fourth of July work program proves that the coke workers, just like other citizens, are not wanting in patriotism nor backward in showing it once they are given to understand that it can be expressed in more than one form. Gratified over the splendid showing of the Fourth, the operators are now mildly hopeful that other precedents can be broken that will institute a Fourth of July order of work six days every week by every man on the job. To accomplish this will be breaking all precedent-breaking records.

What Makes the Tonnage Drop?



WITH ALL OF US the impulse is to look for steady accretions in coal tonnage. Records once made are regarded as merely footholds for another advance. There was consequently great disappointment when the big bituminous tonnage of the week ending July 13 was followed by a drop despite all the propaganda and effort.

It is possible, however, that the great production of the second week in July was the outcome of the holiday in the first week of that month. This put the railroads in better shape to supply cars, and it made the miners more willing to work in the week that followed. Such miners as were idle for several days over the Fourth began to feel the necessity for bringing up their tonnage to its customary biweekly level. The half month, over which a pay period extends, was ending, and the first half having been partly wasted, it was necessary to end up the period with a more generous output or the pay would be less large than usual. This probably accounts for the large tonnage of the second week of July. But how account for the lower production of the third week?

Perhaps the harvest had something to do with that decline. Miners in some cases, men who have left the farm for the mine, especially when living at or near the old home, help in the harvest and assist in threshing. The unpleasantness of the work in the broiling sun is compensated by the pleasure of working with one's kith and kin and neighbors, the joy and excitement of harvest home, and the profit that a few days work will bring, for they are almost the only profit-bringing days of the farmer's year. No one has kept a tab of the number of mine workers who help in the harvest.

In fact few of the operators have attempted to realize the effect that the mobilization for the farm yearly has on the production of their working forces. That mobilization comes unexpectedly, and as the men depend on one another's work the dislocation of the working force adds to the difficulty. Not only the time of the absent men is lost. Other men are laid idle by the idleness of those who are absent.

You Can't Combine Patriotism With Booze

Soldiers and sailors are not allowed to drink in their leisure time—because booze interferes with their business. Mineworkers are cutting out liquor because it prevents them from doing their best at their work, which is mining coal to fight the Kaiser.

DISCUSSION BY READERS

The Wagon Mine a Menace

Letter No. 1—The discussion of the relation of the wagon mine to the present mining situation, which was started some time since in *Coal Age,* seems to have fallen short of its purpose. The intention evidently was to show that that class of so-called mines is a menace to legitimate business.

With the inflation of the selling price of coal, due to the increasing demand imposed by war conditions, wagon mines, or what may be better termed "country banks," have multiplied by leaps and bounds. Such has been the effect on the coal industry, which is now regulated by Government and made to conform to established methods of mining, that the enormous growth of these smaller mines can only be likened to that of a gigantic cancer that is slowly but surely sapping the vitality of the industry.

The fact is hardly appreciated that these mines have, within the past year, dumped upon the coal market hundreds of tons of material resembling coal, but which upon closer inspection is found to be a mixture of bony coal, bands, slate and the refuse of gob piles and rock dumps, mixed with a limited quantity of inferior coal. Had the mines been subject to the same Government regulations that control the output of larger mines, they would have been abandoned long ago as being unprofitable. It is a fact that the product of these mines could not be properly cleaned and the output made to conform to the restrictions imposed by the Government, without subjecting the operations to a prohibitive expense that would have shut down the large majority of them.

THE MINES UNSANITARY AND UNSAFE

Aside from the impurity of their output, these mines are, as a rule, unsanitary and unsafe. The workings are poorly drained and ventilated, and the miner must often work in peril of his life, owing to insufficient and poor timbering. Little or no provision is made for ventilation and drainage. In most cases, these conditions only exist through the fact that the mines do not employ a sufficient number of men to bring them within the regulation of the mining laws of the state.

Only those familiar with mining practice can appreciate to what extent a properly regulated mine where discipline is maintained, is injured by reason of being located in close proximty to smaller openings where the miners are allowed to come and go as they please and are subject to no discipline and where they are not required to clean their coal when loading, but throw bone, coal and slate into the car together. It is not strange that mines where the men are compelled to properly clean their coal have difficulty to hold their men when the opportunity is presented of finding work where they are subject to no such restrictions.

As is well known, the oldest coal-producing companies are standing loyally and faithfully by the Government and striving to satisfy every demand made upon them. The injustice of the situation is apparent to all, and it goes without saying that relief measures should be adopted in the way of Government interference that would place these mines on the same working basis in respect to their product or compel them to close down.

What I have written is the result of personal observation. It is not based on hearsay or the report or experience of others. The keen competition between all mines to secure the needed workmen has never been greater than at the present time, and this fact alone makes it important to urge every measure that will assist legitimate mining and improve the coal situation.

Confluence, Penn. H. E. GRAY.

Loading Coal at the Face

Letter No. 1—How many tons of coal can a man load in a day of 8 hr., when driving a 15-ft. place in a 3½-ft. seam of bituminous coal? I am led to ask this question after reading the announcement of the Poster page of *Coal Age,* July 6, p. 29.

The Poster states that Ed. Blagg, 27 years old, a loader in No. 1 mine of the Buckeye Coal & Railway Co., San Toy, Ohio, loaded 508 tons of coal in 22 working days of 8 hr. each, in the month of May. This would mean an average of 23 tons a day; or, practically, a ton every 20 min. But assuming the cars, in this thin seam, have a capacity of about 1½ tons, we will say that the man must load 16 cars in 8 hr., or a car every 30 min. if he loaded continuously.

Now, for the sake of argument, let us assume that a 6-ft. cut has been made with the machine, in the man's place, during the night. When this coal is blasted down, there will be between 11 and 12 tons of coal ready to be loaded. We will say then that this man loads eight cars from his first machine cut, which is the work he must perform in the first half of the 8-hr. shift.

Arriving at his place in the morning and finding his coal cut, the miner proceeds to drill two or three holes, which he charges and fires. This work, together with the time required for the air current to sweep away the smoke of the blast, will consume, say, one hour and a half, under fairly favorable conditions for performing the task.

The miner must then arrange his track and bring a car to the face for loading, and we will say that, making a fair allowance for rest and some little delay, there remains two hours for loading the eight cars. As each car is loaded, it must be moved back and an empty brought forward in its place. Also, it will be necessary to shift the track from side to side as the work proceeds, or much of the coal will have to be moved some distance in loading. Again, it cannot be assumed that the rib shots will always square the place ready for the next machine cut, and there will be some pickwork that must be done to get the place in readiness for the machine.

The work described as being done in the first half-shift will need to be duplicated in the second half-shift. However, there is nothing to prevent the supposition that, in this case, the miner may have alternated his work between two places, devoting the first half-shift to one place and the second half-shift to the adjoining place. But, to say the least, that the man kept up this daily tonnage for 22 working days, in a single month, is a remarkable achievement, and it must be assumed that things were working uncommonly smooth during the entire time. Most practical mining men will agree that the record is worthy of more than passing notice.

THOMAS HOGARTH.

Coal Run Mine, McIntyre, Penn.

First Aid to the Uninjured

Letter No. 8—I have read with much interest the numerous letters on this subject, especially that of W. H. Noone, *Coal Age*, June 29, p. 1210. I was forcibly impressed with his remark suggesting that, "More than anything else in coal mining is the necessity of aiding men to recognize the dangers with which they are surrounded and take precautions to avoid possible accidents," adding, "This aid must be given to the man before he is injured."

In speaking of the responsibility resting on a mine foreman, however, Mr. Noone says, "He will find it necessary to enforce a rigid discipline in respect to the timbering of working places;" and in another place he states, "It may be necessary to punish a man for carelessness, in order to bring him to appreciate means taken for his safety."

It appears to me that our friend approaches this question of discipline from the wrong side. Let me suggest that a mine foreman's first duty is to establish a system, in the working of the mine, regarding every detail of the work, particularly that of timbering. Without such a system there can be no true discipline. The distances apart of post timbers and timber frames should be specified to conform to the working conditions, so that men would know exactly when and where timber is needed. Miners should then be held responsible for standing the timbers in their places.

What Mine Discipline Means and Involves

Mine discipline does not mean the punishing of men by using harsh or cruel measures. It is my belief that these are not necessary to make men appreciate what is done for their safety. As I regard it, mine discipline simply means operating according to a fixed system and rule that everyone will understand and follow.

Discipline among workers involves three principles: (1) Willingness to obey orders. (2) Perfect understanding of orders. (3) The training necessary to enable the man to do the proper thing at the proper time, even though no one is present to see that this is done. It should be the motto of every man working in a coal mine to perform his work in the same manner whether the boss is present or absent.

The statement that "accidents from blasting are not so many" may be true; but, in the large majority of cases, it is more by good luck than good management, as few mines take sufficient steps to eliminate this class of accidents. Many are following the usages and practice of 100 years ago, using black powder instead of permissible, and allowing miners to fire their own shots instead of employing competent shotlighters for this work. On every hand we find men using short fuse, crimping a cap with their teeth, smoking and using open lights in places known to generate gas. Miners will make up their charges with their lights on their heads and ride motor trips with explosives on their person.

Attention was drawn to the need of greater care and caution in the handling and use of explosives, in the Foreword, Feb. 23; but how many of the suggestions made in that Foreword have received the thoughtful consideration of mine operators and managers. Instead, mine officials are too prone to blame the men for carelessness when proper system and discipline are not used in their mines.

Illinois Mining Law Regarding Explosives

Allow me to refer here to the explicit manner in which the Illinois Coal Mining Law treats the question of explosives. Sec. 19 of the law requires that the delivery of powder in the coal mines be made by the company after the shotfirers have come out of the mines and before the dayshift enters for work, in the morning, and when all electric current is turned off.

No explosives can be carried in the same car with tools and other materials. The miner must keep his powder in a locked wooden box, which must be placed as far as practicable from the track and from other boxes, and no high explosives shall be kept in the same box with black powder; also, detonating caps must be kept by themselves. The law further specifies that not more than five standard charges of powder shall be used in a single shot, in 5½-ft. coal; and not more than four standard charges in seams where the coal is thinner. In closing, let me say that no aid is given to the man before he is injured, unless the management lays down a system of performing the work and maintains a proper discipline.

Mine Rescue Work

Letter No. 2—The subject of mine rescue work opened for discussion by J. S. Gelston, *Coal Age*, July 6, p. 32, is one of the utmost importance to all persons connected with the coal-mining industry. Notwithstanding the fact that we have improved mining laws and mine regulations that afford a greater measure of protection than was possible before their enactment, disastrous explosions and mine fires still occur with great frequency.

When these calamities come and rescue work is needed, there is no necessity to issue a call for volunteers. The trouble, then, is to prevent men from rushing headlong into the mine, regardless of their own safety and heedless of the dangers that will confront them in the wrecked passageways, now filled with poisonous gases, the afterdamp of the explosion. But, being overcome in the afterdamp is not the only danger rescuers must face. In many cases, fires have started and there is every possibility of a second explosion occurring, owing to the presence of gas and dust clouds that have escaped ignition in the first explosion.

Mr. Gelston has asked the question, "When is a man brave and when is he foolhardy in the face of danger, and what is the dividing line; or is that a matter of individual judgment?" In my opinion, the part taken by men, at a time of danger, is the result of their individual judgment. In every walk of life, some men will do things at such times that others of calmer judgment would regard as foolhardy; or, to say the least, fraught with unwarranted risk.

We will all agree that, to accomplish any dangerous work, certain risks must be incurred or no good will result. The willingness to assume risk will vary with the individual's judgment. The old saying is "Nothing risked, nothing gained." However, the more intelligent the judgment, the greater will be the good accomplished, and this thought brings me to consider the value of breathing apparatus.

The Hope That Animates Rescuers

In the letter to which I have referred, Mr. Gelston remarks, "While breathing apparatus can often be employed with advantage when exploring a mine ahead of the air, or in fighting mine fires, it is generally the case that where the mine air is sufficiently foul to require the use of breathing apparatus it is too foul to support life, and there is little hope of rescuing men by this means."

Admitting the fact that the hope of finding men alive, in a mine where they are entrapped inside of a fouled atmosphere, is generally slim indeed, it must be remembered that *hope dies hard in the heart of the miner,* at such a time. Instances are on record where men have been rescued under just such circumstances, by men wearing breathing apparatus, without which they could not have been reached by their comrades. Also, men have been brought out by their rescuers, through the use of "salvators," or half-hour apparatus, applied to the men to bring them safely through the fouled atmosphere, filling the entries.

Again, there are instances where men have been lost, because aid could not reach them for the lack of the needed breathing apparatus. Later, they have been found to have lived hours and even days, in hope of rescue, but finally succumbing to exhaustion. Another instance when men were lost because no breathing apparatus was available at that time was the explosion at the Edge Green colliery, Lancashire, England, in 1902, which I recall vividly because my own father was numbered among the victims.

The "Cherry" and "Bellevue" Disasters

A notable instance is that of the rescue of 21 men, after they had walled themselves in, in a section of the Cherry (Ill.) mine, and were rescued eight days later when all hope had been abandoned. A full account of the Cherry mine-fire disaster, which cost the loss of 259 lives, Nov. 13, 1909, will be found in the Illinois Coal Report for 1910, pages 459-509, inclusive.

Let me cite, in closing, the two Bellevue mine explosions, which occurred Oct. 31 and Dec. 9, 1910. A full report of the disaster is found in the Annual Report of the Department of Public Works, for the Province of Alberta, Canada, for 1911, pages 119-136. In the second explosion, in December, Robert Strachan, an inspector of mines of British Columbia, together with other rescuers wearing breathing apparatus of the Draeger type, succeeded in penetrating into the workings and rescuing several men who would otherwise have been lost.

It is my opinion, also, that artificial resuscitating apparatus, to which Mr. Gelston has referred, in his closing paragraph, has been the means of saving hundreds of lives. If the appliance is kept thoroughly clean and in a sanitary condition, as it ought to be, there is little danger of death from respiratory disease mentioned by Mr. Gelston. James Touhey.

Vancouver, B. C., Canada.

Travel of Electric Current

Letter No. 4—In connection with the discussion of the question as to whether an electric current travels over the surface or through a conductor, which I am not competent to say, it may be of interest to cite the following incident in my own experience.

In our mine, we had used a 00-wire on our trolley road, until the extension of the system and a 3 per cent. grade against the loaded trip made it advisable to use a 0000-wire on the extension.

Everything went well for a time. But, it was noticed that the 00-wire became quite warm whenever the trip reached the 3 per cent. grade. One day when the locomotive was hauling an extra heavy trip up that grade, the 00-wire became red hot. Under the heat, this wire stretched and sagged in the entry. I am inclined to think that this fact would tend to show that the current flowed through the entire body of the wire. If the flow was only on the surface of the wire, it would hardly seem possible for the entire wire to become heated to that extent.

This subject is of importance in connection with the requirements of the bituminous mine law of this state. The law requires that all electric conductors shall be of sufficient size to transmit the required current without danger. In other words, the current capacity of the wire must be such as not to injure the insulation of a conductor or start a fire by the heating of the wire.

Leckrone, Penn. W. H. G.

Elevation of Outer Rail of Track

Letter No. 1—For many years past, my particular line of work has been the laying of mine tracks and switches. On this account I was much interested in reading the brief answer to the inquiry regarding the proper elevation to be given the outer rail of a track when rounding a curve in a mine. The simple rules given in reply to this inquiry struck me as very complete and easily applied.

In this connection, kindly allow me to cite an instance that occurred recently in my own practice when I was required to lay tracks for a cut-off which has given good satisfaction from the start. At the time, I was employed as trackman for the Saline County Coal Co. at Grayson, in this state. We were starting to extend the motor haul into a south entry off the main east. Mules had been employed to haul the coal from this entry, over a back switch onto the main east.

Starting a sufficient distance back on the main east, the plan now was to cut through the pillar so as to

give an easy curve for the motor to reach the south entry. This plan required the laying of a right-hand switch on the east entry and driving a cut-off to the south entry on a curve having a radius of 70 feet.

Coming out of the south entry, the conditions were such that there would be a natural grade of 1 per cent. in favor of the loaded cars, and to overcome this grade on the outer rail of the curve, I decided to raise that rail, starting about the center of the curve and making that the high point so that there would be practically a rise of 1 per cent. to that point and a fall of 3 per cent. from there to the switch on the main east.

Calculating Ordinates for Curving Rails

In order to expedite the work and make the change as quickly as possible, the foreman asked me if I could not curve the rails beforehand so that they would be ready to lay when the cut-off was completed. I agreed to do this and, for that purpose, calculated the middle ordinate for any desire chord, by dividing the square of the chord by eight times the radius, using the formula $o = c^2/8r$.

For example, assuming a chord of 20 ft., the middle ordinate would be $20^2 \div 8 \times 70 = 5/7$ ft., or say 8⅛ in. The quarter ordinates I then took as two-thirds of this, or say 5⅜ in. When all was ready, we laid the iron, surfaced and tamped the ties, bracing the track well against the rib to keep it from moving until the roadbed was set and solid.

Ten-Ton Morgan-Gardner Locomotive Hauling a 40-Ton Trip

The motor was a 10-ton Morgan-Gardner, and hauled twenty 2-ton cars in a single trip. The first day the switch was used I asked the motorman to run slowly and worked up all the low points. The result was that, in a short time, we had a uniformly smooth track all around the curve. Later, the motorman came out over that curve with his controller set on parallel.

Let me say, in closing, that the elevation of the outer rail of a curve depends not only on the radius of the curve and the speed of the trains; but, if the trip is pushing the motor, as it is coming down a grade, the outer rail must be raised more than when the motor is pulling the trip. However, to raise the outer rail too much is as bad as not to raise it enough. It is important to have the curve and the rise of the outer rail as uniform as possible, in order to prevent the swaying to and fro and knocking of the cars against each other when rounding the curve. G. D. York.

Harrisburg, Ill.

Sealing Off Fire on Intake

Letter No. 10—The inquiry of "Ancora," *Coal Age*, June 22, p. 1173, regarding the sealing off of a fire found burning on the intake side of a pair of headings driven in solid coal and generating so small an amount of gas as not to require the use of safety lamps, presents a subject that is always of interest in coal mining.

The fact that these headings are driven in solid coal greatly simplifies the problem of extinguishing the fire, since there are but two openings to consider. Where rooms have been turned, and especially where pillars are being worked, the sealing off of a fire will often require the building of several stoppings in as many different openings. The difficulty is increased greatly where the drawing of pillars and the settlement of the roof have opened crevices to the surface.

Collecting Material and Building the Stoppings

In the present instance, however, all needed material, consisting of the necessary posts, 2-in. planking, nails, loam for filling and cement or clay for sealing all cracks after the stoppings are built, should be sent into the place at once. While waiting for this material, work can generally be started by erecting a temporary brattice of canvas or boards and this should be done at the first opportunity.

An opening should be made in the first crosscut outby from the fire where it is possible to work. A temporary stopping is then first built on the return just inby of this crosscut. The placing of this stopping will greatly reduce the quantity of air passing over the fire and cause the major portion of the current to be short-circuited at the crosscut just opened outby from the fire. If it is necessary to further reduce the quantity of air reaching the fire, a canvas can also be hung in the intake airway just inby of the same crosscut.

When the material arrives on the scene, heavy 6 x 6-in. posts should be set close to either rib and 2-in. planks spiked to them to form the inside wall of a permanent stopping. In the same manner the outside wall of the stopping should be started so as to leave a space of 12 in. between the two walls. This space should be filled with loam and well tamped. When the stopping is completed to the roof, it should be thoroughly sealed with clay or cement. The second stopping should now be built, in like manner, on the intake airway.

Assumed Condition of Air Behind Stoppings

The inquirer also asks, What would be the nature of the air confined in the space behind the stoppings; (1) assuming the first stopping is built on the intake; and (2) when the first stopping is built on the return of the headings? In answer to these questions, let me say it is my opinion that the condition of the air behind the stoppings would be much the same in either case. The oxygen of the air would be consumed by the fire, and carbon dioxide together with a certain amount of carbon monoxide would be produced. If sulphur was present in the coal there would probably be some sulphurous fumes produced besides.

My reason for closing the return heading first is that the pressure of the air on the intake side would then be exerted to restrict the emission of gas from the coal and other strata. On the other hand, if the first stopping was to be built on the intake, it would appear to my mind that a suction would be formed by the air current passing through the crosscut outby from the fire. This suction would be exerted on the return side and tend to increase the emission of gas from the strata.

I confess that this reasoning is not wholly satisfactory to myself, and I have never been able to quite understand why textbooks advise the building of the first stopping on the return air-course, but have hoped that this discussion would make the reason clear.

Cassidy, B. C., Canada. J. W. Powell.

[Mr. Powell should read carefully the explanation given in the letter of William Dickinson, *Coal Age*,

July 25, p. 187, which gives clearly the logical reason for building the first stopping on the return entry, in this case. A like reason is also given in the letter of Thomas English, Aug. 1, p. 236. It may be stated, here, that the emission of gas from the coal and other strata would not be appreciably restrained by the slight change in pressure caused by building the first stopping on the return airway as Mr. Powell has suggested.—Editor.]

Americanizing the Foreigner

Letter No. 1—I was deeply interested in the reading of "Observer's" letter, bearing on the human side of our relation to foreign-born mine workers, which appeared in *Coal Age*, July 25, p. 189. In justice to the efforts put forth by all worthwhile coal companies I cannot agree with his suggestions, in the second paragraph, that we fail to properly assimilate this class of mine workers, and do not appreciate their traits and peculiarities.

As I have stated, practically all of our large coal companies are doing everything in their power to Americanize the foreign element employed about the coal mines of this country. They have insisted that good schools be built to house the pupils and competent teachers employed to educate them.

Work Among the Foreign Women and Children For Their Education and Training

At many of the larger mines, professional nurses and housekeepers have been employed by the larger companies and are at work in the various towns, trying to educate foreign women in the ways and customs of the American people. Playgrounds, equipped with adequate apparatus, swimming pools, community reading rooms and poolrooms have been established. Moving picture theaters and athletic fields, where sports may be conducted, are also a part of all progressive mining towns. In fact, everything that will tend to improve the condition of the foreign-born worker is at hand.

Mine superintendents and the inside and outside officials of all coal mines now do everything in their power to Americanize the foreign-born element in their midst. It is my honest belief that they *do* meet these people with the ready sympathy and the distinctly human attitude that their condition demands, and they *do* try to help them to carve their own destinies as true American citizens.

Results Show the Average Foreigner Will Not Be Americanized

That this work on the part of executives of coal companies and operating officials, at the various mines, has seemingly failed in its purpose is because the average foreign-born worker refuses to become Americanized. The most of these people come here for one purpose, which is to accumulate enough money to return to the old country to spend the remainder of their days on a little farm and live among their own people in comfort. Some, it is true, come here seeking a new home and a place to bring up their children in peace and comfort. They become Americanized and make good citizens, but their number is so small as to be almost negligible.

In spite of all work done by community workers, in various mining towns, the foreign women still run around in their bare feet and retire at night without washing them. In fact, they seldom wash them for several weeks, and this is also true of the children. Those familiar with mining conditions know that foreign children are still born as they were in the old country and American ideas have failed to change this custom. A doctor's services is rarely required. This is one of the things that ready sympathy and the distinctly human attitude have failed to change.

Use Made of Improvements in Houses

In regard to improved living conditions, where bathrooms are a part of the house occupied by the average foreign family, the tub is still used by a good many to hold the supply of coal necessary to heat the rooms. It will certainly take a lot of education on the part of our teachers to impress upon the minds of the average foreign family the fact that the bathtub is to be used to take a bath. They still prefer to do their bathing in the kitchen in front of all the assembled members of the family and boarders, using for the purpose a common washtub.

It has been almost impossible for the average mine superintendent to cure the foreign element of the practice of stabling their cows in the cellar instead of in stables built for this purpose, and in many instances the stable is still there, but the cow is kept in the cellar. There have been cases where chickens were housed in upstairs rooms and the fact only became known when the families removed to other towns.

Foreigners Resent Interference

It is hard for mine officials, at the various operations, to get very close to the foreign element for the simple reason that they resent interference of any kind. In this respect, they resemble the Chinese. It is true that they wear American clothes and, after a long time, do away with celluloid collars and ridiculous neckties; but the things they do not change are the things not apparent, except to the close observer.

In view of these conditions, I admit that, at many of the mines, the management has given up the idea of improving the condition of the foreign element, simply because they realize that the average of the foreign element will have nothing to do with anything that will tend to improve their condition and since they must have labor to carry on the production of coal, it is necessary that they do not go too far in this direction, else this labor will leave and go to a place where they will not be continually interfered with.

I could go on and cite incident after incident where much has been done to improve the social atmosphere surrounding the foreign-born miner, but such improvement has failed in its purpose. This is testified, too, by the fact that our jails are still crowded with such people, as are also our saloons and our streets. In conclusion, I must say that it will take more than motion pictures, hearty handshake or a slap on the back, or the work of missionaries, to inspire these foreign people in the direction of increased patriotic zeal and fervor.

Pittsburgh, Penn. EXPERIENCE.

INQUIRIES OF GENERAL INTEREST

Ventilation Problem

Kindly permit me to present a rough sketch of a section of our mine, lying about 6000 ft. from the main entrance, consisting of the 9- and 10-E and W entries, off the 9- and 10-N. We are not intending to push the north entries further ahead for a long time, as there is enough coal in sight on the east and west entries to last us ten years.

By way of explanation, let me say that the 9-N and the 9-E and W entries are the haulage roads and the

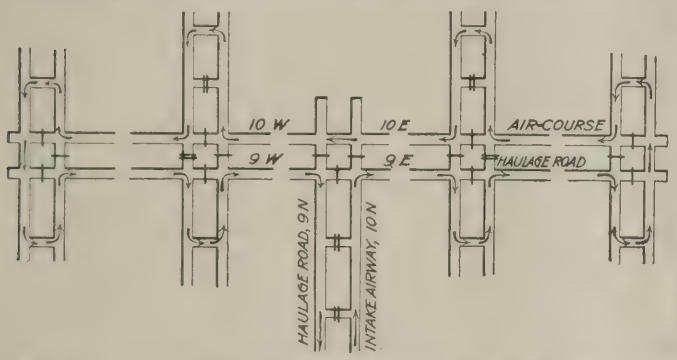

FIG. 1. SHOWING PRESENT COURSE OF AIR CURRENT

return airways, or will be when the present plan is put in operation, while the 10-N and 10-E and W entries will then be the main intake air-courses. At present, the air is coursed through this entire section of the mine in a single current, as shown in Fig. 1.

As indicated in Fig. 2, it is proposed to build an overcast at the point where the 9-E entry crosses the

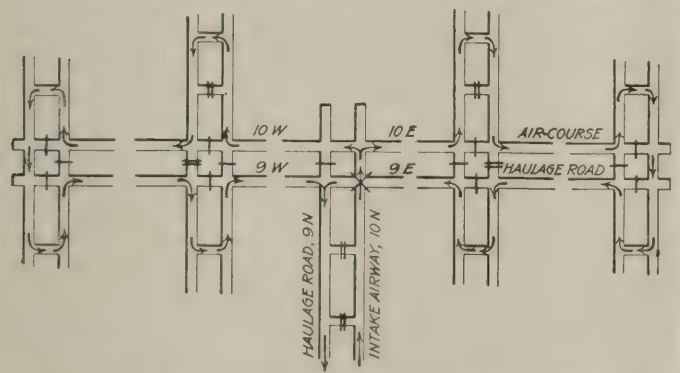

FIG. 2. SHOWING PROPOSED CIRCULATION

10-N. The main intake current will then pass over this air bridge and divide forming two air splits for the ventilation of the 10-E and 10-W entries, respectively. In the development of the mine, rooms will be turned to the right and left of each pair of the butt headings shown in the figure. Owing to the distance of these entries from the mouth of the mine, the air circulating in this section is deficient and will require, the installment of a booster fan to assist the circulation. There will be about 150 men working on the east and west entries, and the question is, Where should the booster fan be placed to produce the best results?

Allow me to ask, Will a "booster" work better when drawing the air or when forcing it through this section? I am inclinded to place the booster in the return current, either on the 10-E or 10-W entry. But, if the booster will work better forcing the air through the section, I would say it should be located on the intake airway near to the overcast. I hope this question will be taken up and discussed by those who have had experience with booster fans.

———, Ill. MINE SUPERINTENDENT.

The question of utilizing booster fans was widely discussed in the columns of *Coal Age*, some years ago, and aroused much interest. There were advocates for and against the installation of boosters in mines, the chief arguments against their use being the possible destruction of the fan, and its inaccessibility in case of accident when it would be most needed. It was shown, however, that there are conditions that exist at times in mines and which require the use of a booster; but emphasis was placed on the fact that such a fan should not be installed as an *essential factor* in the general ventilation of a mine. It will be generally conceded that all essential ventilating apparatus, in fan ventilation, should be located on the surface, where it will not only be better protected and cared for, but will be available and accessible in case of accident in the mine.

In the opinion of *Coal Age*, the province of a booster fan is, as the name suggests, to assist or strengthen the circulation of the air current at a point where it is practically stagnated. Owing to leakage through poorly built stoppings, doors and air bridges, it frequently happens that there is practically no circulation of air at the working face.

Under such circumstances, it will generally be the case that the future development of that particular section of the mine will not warrant a large outlay to overcome the difficulty and improve the circulation by repairing stoppings or rebuilding doors and air bridges. The installation of a booster on the return end of the air circulating in that section will frequently overcome the tendency of the air to leak through bad stoppings, and doors, by creating a depression in favor of the return airway, in the proper course of the current.

A booster fan should never be placed in a position to force the air through a leaky section, as this would only increase the leakage and fail to improve the circulation. The location of the booster must always be on the return side and the fan must be operated to exhaust the air from the intake, inby of the leak.

There is no doubt but that a large number of our practical readers will be glad to give their experiences and suggestions on the use of booster fans. It is a question that should be carefully studied from the standpoint of utility and economy.

EXAMINATION QUESTIONS

Mine Foremen's Examination, Shenandoah, Penn., Apr. 23, 1918

(Selected Questions)

Ques.—What are the factors determining the quantity of air passing in a mine at any given time?

Ans.—The reading of this question is slightly ambiguous. The factors producing the quantity of air passing in a mine, or that determine what quantity of air will be circulated, are the *power* applied to the air current through the action of the ventilator, and the *resisting power* of the mine, as determined by the extent of the rubbing surface and the sectional area of passage; or, more accurately, the *mine potential*, which will depend not only on the rubbing surface, the sectional area of the airways, and the number of splits, but where the splits are located in the mines. For the same potential, the quantity of air in circulation varies as the cube root of the power on the air.

On the other hand, taking the question to mean, What are the factors used in ascertaining the quantity of air passing in a mine, the answer is, The sectional area of the main intake airway and the velocity of the air current at that point. These two factors multiplied together give the quantity of air.

Ques.—A fan driven by a steam engine supplies air in a mine through several miles of air-course. A door is suddenly opened, allowing the air to go directly from the air shaft to the return. Will the opening of this door cause any change in the operation of the fan? Give the reason for your answer.

Ans.—The opening of the partition door at the shaft bottom, thereby allowing the air current to short-circuit at that point, cuts out the mine resistance against which the fan is operating, leaving only the resistance of the fan drift, shafts and the short underground connection between them. The cutting out of the mine resistance will cause the fan to run slower, assuming that the power applied to the fan shaft remains constant. The reason for this is that the volume of air passing through the fan is greatly increased, because of the decreased resistance to its passage when the mine is cut out of the circuit.

But, the work absorbed within the fan varies as the cube of the quantity of air in circulation, for a constant power applied to the fan shaft. This increased absorption of work within the fan itself throws a greater burden on the fan and, as a result, the fan wheel turns slower under the same power applied to the fan shaft. The same is true whether the fan is blowing or exhausting. As far as the action of the fan wheel is concerned, the direction of the flow in and through the mine makes no difference.

Ques.—What particular dangers are there in pillar drawing, and what, in your opinion, should be done to prevent accidents in the performance of this work?

Ans.—Drawing the pillars in a mine causes the roof to fall as the work progresses. It frequently happens that gas is located in the overlying strata of a coal seam, in which case, the breaking of the roof is followed by an outflow of gas, which is liable to accumulate over the falls and endanger the work, since any slight fall of slate may force the gas down on the workmen.

The breaking of the roof may also open a crevice to the surface and permit an inflow of water from surface streams. In any case, the workmen are always in danger of being caught under a fall of roof or coal, owing to the bending pressure that is exerted heavily on the loose end they are working.

In order to prevent accident in pillar drawing, only competent men familiar with the class of work should be employed for the purpose. A plentiful supply of timber should be kept on hand and used. Posts should always be kept standing behind the workmen and these should be carefully watched to observe the effect of the gradual subsidence of the roof.

Except it is known that there is a complete absence of gas, none but safety lamps of an approved type should be permitted to be used, and a good current of air should be made to pass around the pillar and sweep the fall, which should be tested for gas at regular intervals each day. The work of drawing back pillars should be continued regularly, as the dangers increase when the pillars are allowed to stand idle for a few days.

Ques.—Are you in favor of mixed lights in a mine where explosive gases are generated? Give full reasons.

Ans.—No. A mine generating gas should either be worked entirely with open lights, when this can be done with safety by maintaining a sufficient air current to dilute and sweep away the gas that would otherwise accumulate; or, the mine should be worked exclusively with safety lamps. The use of open lights in a mine where safety lamps are required in portions of the mine is always a menace to safety. This is true, not only because an open light will often be carried, unconsciously, into a working place where safeties are used, but a heavy fall of roof in a section generating gas may force the gas out onto the road where open lights are employed.

Ques.—In a mine ventilated by several splits of air, how would you ascertain if any split was passing more than its share of air?

Ans.—The quantity of air required in each split or district will depend on the conditions with respect to gas or dust in that district and the number of men employed therein, and the total quantity of air in circulation on the main intake airway must be divided between the several districts according to these conditions. The mine foreman knows the volume of air that should pass into each district, and it is his duty, when making his rounds, to measure the quantity of air at the mouth and at the inside breakthrough in each district.

COAL AND COKE NEWS

Harrisburg, Penn.

Seward E. Button, Chief of the Department of Mines, during the week held a conference with the bituminous mine inspectors regarding the coal situation, and states that he feels assured that although the number of workers has been reduced at least 15 per cent., the output will be increased at least 15 per cent., in which case the production for 1918 will be about 190,000,000 tons. Every effort is being made by the mine inspectors to see that properly prepared coal is sent to market.

The department is anxious, Chief Button says, to prevent a recurrence of the experience of last winter, when coal of most inferior quality was supplied to the consumers, and the inspectors have been instructed to give every possible aid to the Federal Fuel Administration in the efforts being made to protect the public.

Bituminous Production High

The soft coal production has been moving quite satisfactorily for the month of July. This is said to be due to the common-sense basis put into effect recently, of letting each mine have as many cars as it can load regardless of rating. The evil of the rating system, it is said, is that a mine which might have been a 50-car producer when the rating was made will get 50 cars even though it can load no more than 40, while a neighboring mine, rated at 25 will get only that number and will have them loaded perhaps around the noon hour. Operators say that distribution as per rating must be set aside again, or that mines be rerated, unless Pennsylvania production is to suffer.

Some Interesting Statistics

Figures given by the Central Pennsylvania Coal Producers' Association for two large companies in the central district show that among 3592 employees listed there has been a military registration to date of 846 men—indicating a possible labor loss of 23.5 per cent.

The actual miner, the cutter of coal, has increased his efficiency in spite of handicaps, according to other figures given out by the same association covering the records of 244 operators. Actual miners, loaders, cutters, and others were 8.3 per cent. less in number in May, 1918 than in March, 1917, but the tonnage produced per miner in May, 1918 was 99.6 against 99.5 in March, 1917. Other employees had increased 13.20 per cent. in the period mentioned, so that the tonnage per employee was but 66.5 tons for May, 1918, as compared with 70.9 in March, 1917.

Maximum Prices for Wagon Mines

Maximum prices that may be charged by wagon and truck coal mines in the Pittsburgh District for coal, and certain rules and regulations governing the operations of mines have been established by the local fuel administrator.

The following are the rules, issued July 30, controlling prices:

(1) For coal not moving by rail, a manufacturer or large consumer making a blanket contract with a wagon mine for the entire daily output of any one or more of these mines, delivery to take place each day of the week as the coal is produced, the maximum price shall be $2.45 per net ton, f.o.b. mine platform.

(2) For all coal so purchased in large quantities for public institutions, hospitals, office buildings, large apartment houses, small manufacturing operations, mercantile establishments, and like institutions, including a supply to retail coal dealers, the maximum price, (where not taking the full and complete output of the mine and providing for its continuous operation without interruption) shall be $2.75 per net ton f.o.b. mine platform.

(3) For those consumers of coal ordinarily covered by the term "domestic users" and taking only small quantities, and especially any consumers not in the first and second classes above mentioned, the maximum price shall be $3 per net ton, f.o.b. mine platform.

Charleston, W. Va.

A special appeal was made by both D. R. Lawson, district representative of the Fuel Administration and by C. F. Keeney, president and Fred Mooney, secretary of the Mine Workers of District 17, last Monday to the miners in the Fairmont region urging them to produce every pound of coal possible in order that the government order of 150,000 tons of coal to be shipped to Curtis Bay last week might be complied with without failure. As a result of such an appeal and with a better car supply than was available the week before, production jumped in the Fairmont district, both operators and miners bending every energy to fulfil government expectations. The Baltimore & Ohio R. R. was under special orders to have an ample supply of cars on hand.

Cars were more in evidence last week in the Fairmont field than during the week previous when there was a decided slump but numerous factors led observers to believe that the output would fall short of the quantity expected. At one mine for instance, most of the miners laid off to go to a funeral. That has been the case elsewhere and has resulted in an agitation for the adoption of the practice now in vogue in the hard coal fields of designating a small committee to represent the miners at funerals in the future. With the Fairmont region mines under order to supply Curtis Bay with 150,000 tons last week, manifestations of indifference on the part of some miners caused apprehension in some quarters lest the district fail to meet the requirements for these shipments.

While production has undoubtedly increased in this state as reflected in figures made public at Washington, the maximum output has not been reached by any means and labor shortage still gives operating companies much concern. The Kanawha district has shown as much of an improvement as any one region, but producers in that district feel that if every man will only exert himself to the utmost, production can be still further increased. Speakers—soldiers and civilians—in mining towns and in the moving picture theaters have been talking nothing but production for the last few weeks and this campaign has made itself felt, but the miners are not yet fully awake to the responsibility resting upon them and this, it is believed is due solely to the tactics practiced by a few local leaders. As soon as this trouble reaches a head, mine workers will begin to produce startling results.

Weekly Production Is High

While the weekly production of the Pocahontas and Tug River fields is averaging over 450,000 tons a week, there is still a production loss. An improvement has been noted there within the past week but there is still a labor shortage which precludes maximum production. In no coal district now is lack of cars interfering to any appreciable extent with production.

New River operators are confident of being able to exceed all records for production in August, unless unforeseen circumstances interfere with their plans. Producers had hoped to be able to do this in July but the Fourth of July holidays disorganized their plans and production fell off that week.

While the average output in the New River district is about 310,000 tons of coal a week it has been better than that in the recent past. There has been absolutely no complaint on the score of car supply and in the New River field labor is exerting itself to a greater extent, though there is said to be room for further improvement.

The Kanawha district went "over the top" during the last week in July with the biggest weekly production of the year—221,407 tons—and likewise July was the biggest month, the total loads delivered being 42,620. The increase of about 20,000 tons over the week previous was due to greater efforts on the part of the miners, the total hours, worked being 6265, only 532 hours being lost through shortage of labor. Car shortage was responsible for 393 hours loss. The Chesapeake & Ohio R. R. has announced that the coal movement for July was the biggest the road has ever had by 300,000 tons.

PENNSYLVANIA

Anthracite

Wilkes-Barre—The Lehigh Valley Coal Co. on Aug. 1 put into effect a redivision of its districts in the anthracite field so as to better meet the heavy demands for fuel. Through the change more intensive effort is aimed at and greater concentration of activity on the part of officials, whose territoral units have been decreased. The rearranged divisions are grouped as follows: Lackawanna division: Sheldon Jones, headquarters, Wilkes-Barre; Luzerne division: George P. Gallagher, division superintendent, headquarters, Wilkes-Barre. Wyoming Division: John H. Heartter, division superintendent, headquarters, Wilkes-Barre. Lehigh division, headquarters, Hazleton, D. S. Wolfe, division superintendent, George Wood, division engineer. Hazleton Division: headquarters, Hazleton, H. W. Montz, division superintendent, C. A. Garner, division engineer. Delano division, headquarters, Mahanoy City, John W. Price, division superintendent, M. I. Terwilliger, division engineer. Girard division: headquarters, Lost Creek; F. H. Wagner, division superintendent; E. O. Holderman, division engineer. Locust Mountain division: H. J. Heffner, division superintendent. Blackwood division: Headquarters, Blackwood; C. N. Mortimer, superintendent.

Jeddo—Although not completely housed, the new Jeddo No. 4 Washery of G. B. Markle Co. is preparing coal. The gift of two war savings stamps to each employee engaged in its erection was much appreciated by the men.

Freeland—During August "movie" goers throughout the country will see a moving picture of the G. B. Markel Co. employee's community garden, a New York moving picture house having taken a view of it on July 29.

Port Blanchard—On July 25, No. 14 colliery of the Pennsylvania Coal Co. had the biggest day in the history of its production, loading 150 railroad cars of coal in 24 hr., shipping 6500 tons. Company officials and men are alike elated over this Hun-crushing achievement, ranking with the launching of a ship in importance to the nation at war.

Harwood—Lightning forced the local station of the Harwood Electric Co. out of commission on July 30, and as a result several mines which receive electrical power from the plant had to suspend operations. Work was resumed the next day.

Powder used in the mines in the Lehigh region, which in the past has been shipped over railroads to the collieries, is now being hauled by motor trucks. This being done to relieve the railroads and insure the prompt delivery of the explosives so as not to interfere with mining operations.

Duryea—After battling with a serious fire that originated in the William A. Colliery on July 27 for many hours the employees of the Lehigh Valley Coal Co succeeded in getting it under control, thus saving the mine from being flooded. The fire was discovered by a fireboss making his rounds, who immediately gave the alarm. The fire in the mine started in what is known as Bates plane, on the east side of the Lackawanna River, and affects 18 places. Considerable timber is used in that section of the mine and how the flames originated no one seems to know. The men were worked in teams of five and could only work 15 minutes at a time.

Coal Township—Disregarding the state law by opening a safety lamp in a gaseous section of the Henry Clay Colliery that he might light a cigarette, John Conovage, a miner, set off a body of gas and both he and his laborer were probably fatally burned.

Beaver Meadow—High water affected production in the mines of the Lehigh Valley Coal Co. in this region on Aug. 1. Miners were driven out of No. 2 workings when Sulphur Creek overflowed its banks and broke into the mine. Suspension was imperative, despite the national demand for fuel, and the situation was made worse for the Valley output when the Beaver Meadow silt dam burst and the column pipes at the Jeansville breaker gave way.

Pittston—In compliance with the decision that all draft boards can exempt all mining men of vital importance to the coal industry, the Pennsylvania Coal and Hillside Coal and Iron Companies have established a central city office at room No. 11, post-office building, this city, and from this point all matters in connection with drafted employees will be handled. It is the intention to investigate each case and only seek exemption for those whose positions cannot be easily refilled. No claims will be filed for exemption of those men who are known to be habitual loafers and men who lose time weekly.

Browntown—The settling of the surface in Cork Lane, which started on July 27, still continues and the working had not ceased on July 31. A large force of men were at work dumping in ashes and raising the Delaware & Hudson and Central R. R. of New Jersey tracks. The Delaware & Hudson passenger station is badly affected as the whole business has settled.

The settling covers a big area and is said to be caused by workings in the Hillside Coal and Iron Co.'s mines.

Hazleton—Many miners in the employ of the Lehigh Valley Coal Co. have objected to the action of that corporation in exchanging First Liberty Loan Bonds for those of the later issue paying higher interest. The men took out the bonds on the installment plan, through which deductions were made semi-monthly from their wages. The bonds are to be distributed the first of the month and when it became known that they are of the second issue requests began to pour in that these were not acceptable. The men want the honor of having the bonds of the first allotment as evidence of their patriotic spirit.

A special grade of anthracite leaves the Hazleton field each week by express for use in the Government factories making gas bombs.

Bituminous

Connellsville—Operators in the Connellsville region engaged in salvaging screened coke from ash dumps are well pleased with the recent fuel administration order fixing a maximum price for screened coke of $1 less than the maximum government price for selected foundry coke f.o.b. cars. The order means that any cleanly screened coke from ash dumps which can be used as domestic fuel can be sold at a maximum of $6 whether it is shipped for domestic use or not.

Punxsutawney—The Anita Coal Mining Co. has re-opened the old Horatio No. 2 mine of the Berwind-White Coal Mining Co. at Horatio near here. This mine was abandoned by the Berwind company 22 years ago on account of the high cost of getting the coal. The mine was a "wet" one and when a fault was encountered at the face of the main slope it was stopped. The Anita company has installed large pumps and retimbered the main heading the entire length, cut through the fault and opened a fine field of coal. Shipments will be made over the Pennsylvania Railroad.

Indiana—The first move toward bringing the general offices of the Rochester & Pittsburgh Coal and Iron Co. to this city was announced last week when it was stated that the electrical and mechanical engineering departments would be moved from Punxsutawney. The offices will be located in the Savings and Trust Building with the other offices of the company until the new office building is erected on Church Street.

Iselin—The Lowther Coal Co. has begun shipments from its mine near Clarksburg. The opening is on the Marock farm in the Pittsburgh gas seam. A Galion steel hoist and tipple has been installed at the foot of the incline plane. Shipments will be made over the Buffalo, Rochester & Pittsburgh Railway.

WEST VIRGINIA

Charleston — A new power unit will shortly be added to the plant of the Gauley Coal Co., this to be a 150 kw. plant. New motors, mining machines, etc., will be installed.

Welch—Another opening has been made by the Flat Top Coal Co. on the Welch seam above the present opening at its English plant. The same tipple is being utilized in connection with both openings.

Fairmont—After two years of almost constant activity in repairing the damage wrought by an explosion in 1916, mine No. 7 of the Jamison Coal Co. will probably be reopened by Sept. 1, according to an announcement made by J. M. Wolfe, superintendent of the West Virginia division of the company.

Clarksburg—W. M. Hornor, L. W. Garrett and other business men of this city have purchased a large tract of coal land owned by the late George M. Whitescarver of Grafton and are making arrangements to open several mines on the property acquired in the near future. The coal is situated on Coal Run a few miles south of Grafton.

Elkins—By November 1 the West Virginia Coal & Coke Co. expects to have its No. 12 mine near Bower, on the Coal and Coke Ry., in operation, work having been started on this development. No. 12 is to be a drift mine located about a mile south of Bower. The tipple is to be so constructed that shaker screens may be installed later, if desired, but immediate plans provide for dumping run of mine coal only. No. 12 mine is to work an area of approximately 500 acres of Pittsburgh coal. The mine will be worked on a retreating room and pillar system and in order to hasten development, a number of headings will be started from the outcrop, with an outside tram-road to the tipple. This will be abandoned when the inside hallway is connected through.

ALABAMA

Birmingham—The Birmingham Coke and Byproducts Co. announces that it will construct a battery of byproduct coke ovens and plant for the recovery of the byproducts of the coal, on a site near Boyles, Jefferson County, the new enterprise to cost in the neighborhood of $3,000,000. Work on this plant will commence as soon as materials can be assembled, it being the intention to have it ready for operation in about ten months. The Federal Government will render financial assistance toward its construction and has contracted for the output of coke, to be used at the air nitrate plants at Sheffield, and will also take the production of toluol, sulphate of ammonia, etc., for use in munition plants. The coal for supplying these ovens will come from the mines of the Majestic and Imperial coal companies, which are located a short distance from the site of the by-product plant, and which are owned by the incorporators of the new company. The new firm is officered by Morris W. Bush, president; Horace Hammond, vice president and treasurer, and H. L. Morrow, secretary, all of Birmingham. A. P. Bush, of Mobile, is also a stockholder in the company.

KENTUCKY

Madisonville—It is reported that the small mines around Madisonville, which recently were cut off from the car supply by the Louisville & Nashville R. R. Co., are again securing cars.

Hazard—The Solar Coal Co., operating at the mouth of Willard Creek, has started loading out coal, shipping its first car a few days ago. The company has made improvements to the property which cost about $150,000. J. W. Estep is superintendent of operations for the company.

Sturgis—Fire breaking out in Mine No. 8, of the West Kentucky Coal Co., during the night of July 23, was not discovered until the morning of July 24, when it had obtained such headway that it became necessary to abandon the mine temporarily, and seal it up. It is stated that A. E. Anderson, who had charge of the pumps, was caught in the mine. Rescue parties were driven back by heat and gas. According to the most recent reports the fire was still burning, and the man's body had not been recovered. The blaze is thought to have started from a short circut.

OHIO

Mortonville—William B. McCracken of Lancaster, O., has leased from the Buckeye Coal & Ry. Co. a tract of 160 acres on the Toledo & Ohio Central RR. near Mortonville which will be developed at once by driving an entry. The seam is the usual No. 7. The product will be sold through the Buckeye Coal and Ry. Co.

INDIANA

Petersburg—The Globe Coal Company, operating a stripping mine at Sugar Ridge, four miles east of Petersburg, is building a sawmill plant and will saw lumber with which to build houses at a town site now being developed. A reservoir is being built and a railroad switch four miles long, with a bridge over Patoka River, is under construction. The company has appealed to the state for 50 more prisoners to work on the railroad grade. Already 52 men are on the job, in addition to scores of others employed in Petersburg and neighboring towns.

Carlinville—Work on the Standard Oil Co.'s No. 2 mine, northeast of here, has been stopped on account of the quicksand and water encountered at a depth of about 100 ft. It is expected that the abandonment will be only temporary. The plan is to resume work as soon as material to make the working conditions safe is received. In the meantime work is being pushed night and day at Mine No. 3, on the same tract. But for the difficulty encountered in Mine No. 2, work would not have been begun on No. 3 until No. 2 was completed. Mine No. 4 is expected to be ready for operation by Oct. 1.

Virden—Fossils of what are believed to have been prehistoric reptiles are being found in considerable numbers in the North Mine here. One specimen is 14 ft. long and 7 in. in diameter and has a wedge-shaped tail. Another is 6 ft. long and a third 3 ft. long, all of the same general characteristics. They are found between layers of rock and slate and the miners say that there are many visible in the formation.

Springfield—The first national convention of co-operative stores will be held here Sept. 25. Hundreds of delegates are expected. The sessions will be held at the hall of representatives. Governor Lowden will deliver the address of welcome. There are now more than 1000 co-operative stores in this country.

Duquoin, Ill.—Evan D. John, director of the Illinois Department of Mines and Minerals, announces the following itinerary for the Miners' Examining Board for August: Benton, Aug. 5; Harrisburg, Aug. 6; Herrin, Aug. 8; Duquoin, Aug. 10; Belleville, Aug. 12; Collinsville, Aug. 13; Litchfield, Aug. 14; Taylorville, Aug. 15; Danville, Aug. 16; Peoria, Aug. 17; Canton, Aug. 19; Springfield, Aug. 20.

Personals

Charles H. Eskridge, who for a number of years has been with the traffic department of the Chesapeake & Ohio R.R., has resigned to go to Ashland, Ky., to take up traffic work for the Ashland Iron and Mining Co. He made the change on Aug. 1.

Delwyn Wolfe, new superintendent of the Lehigh Valley Coal Co., will make his home at Jeanesville and have charge of a part of the present Hazleton Division, which has been divided with the present superintendent, Mr. Montz. Further changes in the operating personnel are expected.

J. H. Walker, president of the Illinois Federation of Labor, has announced his candidacy for international president of the United Mine Workers of America in the coming election on the second Tuesday in December. Mr. Walker lives in Danville, Ill., and is a member of Local No. 503, of Westville, Ill.

W. P. Burgess, engineer in charge of the Birmingham mine rescue station for several months past, has tendered his resignation to the government and will enter the service of the Bessemer Coal, Iron and Land Co. as superintendent of the Belle Ellen division. Mr. Burgess' successor has not been announced.

J. Fred Morlock, manager of the Morlock Collieries Co., has taken a controlling interest in the Victor mine at Strattonville, Penn., and will be made president of the company. He has also added several new business branches to his office operations at Buffalo, N. Y., among them the Tri-states Securities Co., for the handling of coal lands and other properties. Other coal mines are under negotiation.

Obituary

John R. Powell, pioneer squib manufacturer of this country, coalman and banker, died at his home, in Plymouth, Penn., on July 29, of uremia. Mr. Powell was born in Wales, May 6, 1847, and emigrated to this country in 1865. He erected a squib factory in 1878 and immediately began the manufacture of squibs used in mining throughout this country. The industry was a success from the start and has continued so during the intervening years. He secured his first patent in 1879. While Mr. Powell was interested in a number of coal properties and in numerous concerns which turn out mining supplies, it was in the squib business that he established a reputation, as the product of his factories is in use in every coal and other mines throughout the country. He is survived by his widow and one daughter.

Industrial News

Bluefield, W. Va.—The Pocahontas and Tug River districts produced during week ending July 27 the greatest tonnage ever mined, 473,896 tons.

Fairmont, W. Va.—Automatic scales are to be installed in all the mines of the Consolidation Coal Co. in this region in the near future.

Petersburg, Ind.—A Vincinnis coal company has leased 2500 acres of coal land, just west of Hesmer, six miles south of Petersburg and will open a railroad mine this fall.

McDowell, W. Va.—A number of new houses for miners are being built by the McDowell Coal & Coke Co., of which H. W. Rawson is superintendent, at its plant at this place.

Gillespie, Ill.—The Illinois Pyrite Co. has been incorporated with a capital of $25,000 to deal in pyrite coal and other minerals. The directors are William Watson, Fred E. Long and R. M. Depew.

Hyer, W. Va.—The Bens Run Coal Co. has been organized with a capital of $50,000 to mine for coal in the Hyer district. C. W. Karns, J. E. McDowell and J. P. Gates are the principal incorporators.

Louisville, Ky.—The Union County Mining Co. has been recently organized with a capital of $300,000 to develop coal properties in Union County. The incorporators are William Jarvis, Fred Reiss and R. F. Peters.

Armor, W. Va.—The Dempsey Coal Co., recently incorporated with a capital of $50,000, has perfected its organization and is planning for the immediate development of about 300 acres of coal properties in the Inez, Ky., district. Lewis Dempsey is president.

Hawesville, Ky.—The Central Kentucky Block Coal and Mineral Co. has been incorporated with a capital of $200,000 to operate coal properties in the Hawesville district. Harry Myers, Charles E. McDavitt, and Stanley Allen are the incorporators.

Louisville, Ky.—The Elkhorn-Jellico Coal Co., operating near Whitesburg, Ky., has secured 2,000 acres of land, and plans opening a large mine, and the construction of a considerable mining town, including schools, churches, moving picture theatres, etc. M. K. Marlowe and others are interested.

Columbus, Ohio—Numerous wrecks and derailments have occurred recently on the Kanawha & Michigan, arising from the use of heavy foreign equipment. As a consequence the production of the mines along the line has been greatly reduced. One day recently 10 derailments were reported.

Columbus, O.—Engineers employed in the mines of the Ohio Collieries Co., in Athens county, who quit in consequence of a dispute over wages, have returned to work, with the understanding that the difference will be adjusted by the Federal authorities. The strike caused the idleness of 1000 miners for one day.

Charleston, W. Va.—Out of 55 counties in West Virginia, coal is shipped into only 14, according to a statement recently made by State Fuel Administrator J. W. Barnes. Little, if any, coal is used in some West Virginia counties, such localities having an abundance of natural gas and where that is not the case, an ample supply of wood.

Buckingham, Ohio—A partnership known as Summers & Chilcote has been formed by J. H. Summers and C. M. Chilcote of Columbus and has purchased from Charles Schroeder of Buckingham a tract of 30 acres of coal and considerable worked over land. The purchasers will increase the output, which will be marketed through the Buckeye Coal and Ry. Co., of Columbus.

Charleston, W. Va.—Work will be started at once on extensive improvements to be made to the plant of the Dana Coal Co. at Dana. The mine to be operated was recently purchased from the Canadian Pacific Coal Co. and will be completely electrified. Work is to start at once. The yearly output of the company will be 100,000 tons when all improvements are completed.

St. Louis, Mo.—The City of St. Louis is storing coal at Baden and Bissell's Point. The quantity now stored is about 7000 tons. The city's requirements are about 300 tons a day. Last year this was obtained for $1.90 f.o.b. mine. The contract is still in force and is subject to renewal, subject to increase in freight rate, which will make the approximate cost, delivered in St. Louis, about $2.85.

Oklahoma City, Okla.—The Gunther Coal Mining Co. of Tulsa, Okla., has been organized with a capital stock of $150,000 for the purpose of developing some extensive coal land leases near that city. The charter of the company has just been filed in the office of Secretary of State Lyon, and shows that the incorporators are: S. A. Gaskill of Claremore, and A. C. Gunther and F. A. Vernon of Tulsa.

East St. Louis, Ill.—Fuel Administrator Baxter gave another hearing Tuesday to East St. Louis coal dealers who are asking permission to increase the retail price 5 cents a bushel. After several had testified that they could not do business at the present prices, H. H. Mott of the Granite City Cooperative Coal Co. testified that a good profit could be made at the present prices. The administrator has the matter under advisement.

Dallas, Tex.—This town is comparatively safe from dangers of a fuel famine this winter, according to local coal dealers, who say that never before have there been as many and as heavy deliveries of advance orders for coal. Practically all yards have been running as many wagons making coal deliveries through the summer months as are operated during the winter months, and nearly every family in Dallas has sufficient coal in the bins to last through the winter.

Elkins, W. Va.—Three Y. M. C. A. buildings for miners are to be erected by the West Virginia Coal and Coke Co., one at Bower, one at Norton and one at Mabie, the latter to be somewhat of a community building, since other companies there are to share their proportional part in the erection and maintainance of the building. As soon as final plans are approved, construction work will be begun. The same company is building a number of houses of the bungalow type for miners at its Harding plant.

Columbus, Ohio—It is announced by the Ohio Fuel Administration that the plan to have all large users of coal sign questionnaires, showing their needs and containing much other information, will be put into effect in the near future. After the questionnaires are filled out and sworn to inspectors from the Federal Administration will be dispatched throughout the state to see if any saving of fuel can be made. It is estimated that a saving of from 25,000,000 to 50,000,000 tons can be made by more efficient methods of firing.

St. Louis, Mo.—Disregard of State Fuel Administrator Crossley's order to make last Monday night the first lightless night was so general that Secretary W. E. Mount of the St. Louis Fuel Committee wrote to the chief of police next day requesting enforcement of the order. The observance was better Tuesday night. The excuse made for violations Monday night was that competitors violated it and that orders had not been received to extinguish the advertising and ornamental lights. Curtailment of street lighting is also to be enforced.

Harmersville, Penn.—Four hundred new houses are being built at a new mining town three miles from this place. The houses are five and six room cottages, thoroughly modern, with water, sewer, gas and electricity and equipped with fireplace and two chimneys. The mines are now producing from 500 to 700 tons of coal daily and when the new houses are completed and occupied there will be labor enough to produce about 5000 tons a day. A spur railroad connects the new town with Harmersville. The town has a commissary and two privately owned stores. The mine is a new one.

Cincinnati, O.—The Hamilton County Fuel Administration, anticipating a heavier demand for the general supply of fuel next winter than can be met, is urging manufacturers, public institutions, and other consumers entitled to special consideration and priority in the matter of coal supply, to have their names placed on the preferential lists of the National Fuel Administration, in order that they may be as fully assured as possible of a coal supply. This attitude is one result of the prospect that virtually all West Virginia coal will now be sent to the East instead of coming West for Cincinnati and other cities.

Howe, Okla.—The large coke ovens built by the Mexican Gulf and Transportation Co., near Howe, Okla., have resumed operations after having been idle for more than 15 years. This plant, containing 100 ovens, was abandoned when it was found unprofitable more than 15 years ago, and the plant had fallen into decay. It was purchased last December by the Howe-McCurtain Coke Co., of Howe, Okla., and since that time has been completely renovated and put in good order. This company also operates the coke plant at McCurtain, Okla. The company is now sinking its No. 4 mine on coal land near Howe, and will use the entire output of coal for coking purposes.

Columbus, Ohio—No more Pocahontas coal may be shipped into Ohio for domestic consumption. J. H. Frantz, Ohio fuel administrator for the state, thus announced recently upon his arrival from Washington, where he spent most of the week conferring with the fuel administration. This kind of coal is to be reserved for the navy and for the production of byproducts in coke ovens. Mr. Frantz also announced that western Kentucky had been added to the Ohio coal zone and that coal from that section could be shipped into Ohio. This coal will be chiefly for Cincinnati, Hamilton and Dayton and contiguous territory. Hocking coal and West Virginia splints will be available for the Columbus territory.

Rockville, Ind.—T. F. Gaebler, fuel administrator of Parke County, is making a special campaign to save as much timber as possible for fuel purposes and thereby to relieve the shortage of coal. Mr. Gaebler is interesting farmers in cutting and hauling "dead and down" timber which ordinarily goes to waste. There are 65 coal mines in Parke County and with the burning of thousands of cords of wood, the county will be able to ship many more tons of coal than usual. Mr. Gaebler will refuse to issue permits to farmers to buy coal unless the farmer is able to show that there is no wood on his farm going to waste. Martin Rehfuss, Jr., fuel administrator of Marion County (Indianapolis) is following the same plan.

Uniontown, Penn. — Twelve thousand acres of the best quality of coking coal in Greene County, situated in Cumberland and Jefferson Townships with a frontage along the Monongahela River, recently passed into the control of the H. C. Frick Coke Co. and $7,000,000 was distributed to creditors of J. V. Thompson with the delivery of the deeds in the so-called Frick deal. This is the first tangible result of efforts made to liquidate the vast Thompson estate since the financial crash in January, 1915. Mr. Thompson's interest in the deal was 7,255 acres and the trustees were given $3,797,472.25 for distribution to mortgage holders. Other deals are now pending, one being for the sale of 5,000 acres of "back" coal for $2,000,000. The Frick deal was tangled in litigation for more than two years before the deed was passed.

St. Louis, Mo.—Barge line freight service between St. Louis and New Orleans will be in operation on a weekly schedule on and after Sept. 1, according to an announcement of A. W. Mackie, manager of the Mississippi River section of Federal Barge Lines, on his return from a trip along the lower Mississippi with M. J. Sanders, federal director of waterways. The Government has acquired 40 steel barges and will have four or five steamboats to tow them. Construction of equipment will be pushed and as soon as possible a twice-a-week schedule will be put into effect. The plans call for towboats with motors of 2000 hp. and over and barges of from 1000 to 2000 tons capacity. Mackie expects that a combination rail and water rate will be made which will enable shipments to be made over both transportation systems.

Fairmont, W. Va.—The record of loading coal and coke on the Monongah division of the Baltimore & Ohio R.R. during the month of June as compared to the three preceding months has been completed by F. J. Patton, secretary of the coal operators' association, and shows:

	East	West	Total
June	18,363	5,375	23,734
May	17,030	4,972	22,002
April	15,543	4,896	20,439
March	15,493	3,060	18,553

The figures shown above include 805 cars of coke and 852 box cars loaded by team track haulers. There was a total of 22,077 cars loaded at tipple mines during June which is 51.16 of the rating of the region. Mr. Patton has a list of 225 team track mines in the Fairmont district and is not certain that he has them all.

Philadelphia, Penn.—A "get-together" meeting of anthracite operators was held recently with the anthracite committee of the U. S. Fuel Administration. The object of the meeting was to "check up" on the anthracite output with a view to increasing it if possible. Operators, representing companies shipping to all destinations permitted by the Fuel Administration, had the situation explained to them. Special stress was placed on the companies seeing to it that consignees empty cars the same day as received, if humanly possible. A speeding up process was urged that would enable the railroads to return "empties" to the mines as quickly as possible. The operators agreed to follow all plans and suggestions likely to expand production. They wanted it understood that if it is in their power and no further depletion of the mine-worker's forces occurs by draft and other causes, they will do their best to see that retail dealers get their advance orders filled to the last ton by Nov. 1. They figured that no really cold weather will come before that date to entail any fuel hardship on the consuming public.

MARKET DEPARTMENT

Weekly Review

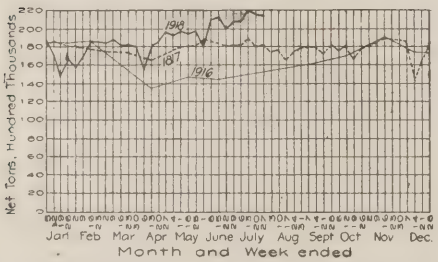
Production High, Car Supply Good and Lake Movement Heavy—Output Well Up to Present Requirements, but Consumers Somewhat Apprehensive for the Future.

PRODUCTION has dropped off slightly from the high records of the recent past. This diminution in the output is, however, not particularly serious and if the present rate can be maintained there can be no such suffering for want of coal as the country experienced last winter.

The car supply has been generally good, many localities receiving full rating. In other regions some mines and some districts have been served with only enough cars for a few days' work per week. Such cases have, however, been the exception rather than the rule.

The coal supply problem is still one of transportation rather than production. It has been fairly well demonstrated that if the mines are supplied with cars they are, as a general rule, able to turn out a heavy output and one well up to the needs of the country. One or two roads have had such heavy traffic in coal that much congestion with some wrecks and derailments has resulted.

In the West and Middle West production is well up to the demand and certain grades and sizes are still selling below the Government schedule. In the East, however, particularly along the Atlantic Seaboard, demand is strong and dealers are unable to accumulate any stocks except of one or two of the smaller sizes. Of these there is now a slight surplus but it is questionable if this would be maintained were bituminous coal available with which to mix the fine anthracite.



The Lake movement has been heavy but receipts at the Upper Lake docks are still behind the Government schedule. Every effort is being made to keep the shipments to the Northwest by water at a maximum as it is believed that by so doing all requirements of that region can be taken care of by the close of navigation.

One incident of the week, small in itself but which may be far-reaching in its results, was the closing of four small mines in the Pittsburgh district because they shipped dirty coal. It is evidently the intention of the Fuel Administration to tolerate no such practices in this respect as caused such justifiably adverse criticism of the industry as was heard last winter.

Particularly in the East no one is sure exactly "where he is at." Although receipts are about ample to present requirements it is recognized that the future is uncertain and in many quarters considerable apprehension is entertained.

WEEKLY COAL PRODUCTION

The output of bituminous coal in the United States declined approximately 1 per cent. during the week of July 27. The production (including lignite and coal coked) is estimated at 12,802,000 net tons, a decrease compared with the week pre-

ceding of 121,000 net tons but an increase over the corresponding week of 1917 of 1,471,000 net tons or 13 per cent. The average daily production is estimated at 2,134,000 net tons as against 2,154,000 net tons during the week of July 20 and as compared with 1,889,000 net tons during the week of July 27, 1917.

The present week's output while 343,000 net tons or approximately 3 per cent. in excess of weekly requirements of 12,459,000 net tons during the balance of coal year to make up the deficit to date, is nevertheless 1,300,000 net tons or 9 per cent. behind the weekly requirements during the balance of the summer months to make up the deficit to date. The difference between the summer requirements and those specified for the balance of the coal year is accounted for by the necessity to ship practically all lake coal during the summer months and 50 per cent. more tidewater coal to New England during the summer than in the winter. Production to date is approximately 15,000,000 net tons behind schedule, and in order to meet all requirements as outlined by the U. S. Fuel Administration it will be necessary that the output of coal during the last of the summer months, August and September, be equivalent to over 14,000,000 net tons per week, 714,000 net tons or 5.5 per cent. in excess of the record week to date.

Anthracite shipments increased slightly during the week, the total movement amounting to 40,942 carloads.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: July 6	July 13	July 20	July 27
Bituminous shipments, 123 roads.	180,090	235,291	229,770*	227,893†
Anthracite shipments, 9 roads...	31,493	42,419	40,664†	40,942

* Revised from last report. † Subject to revision.

Beehive Coke — Production of beehive coke in the United States declined slightly during the week of July 27. Preliminary estimates place production at 617,000 net tons, an average per working day of 103,000 net tons as against 105,000 net tons per working day during the week preceding.

The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week of July 27 at 348,180 net tons and operation of the plants at 77.5 per cent. of present capacity as compared with 76.6 per cent. during the week preceding. Yard labor losses amounted to 19.4 per cent. and losses of time due to all other causes to 3.1 per cent.

The same operators produced 168,650 net tons of coal during the week of July 27.

Byproduct Coke—Working conditions of the byproduct industry in the United States varied but little during the week ended July 27. The operators of the country produced 517,664 net tons, working their plants at 91 per cent. of their present capacity, as against 91.2 per cent. during the week preceding. Material increases occurred during the week in Maryland and Massachusetts, while Kentucky was the one state reporting a material decrease. The plants of three states, Massachusetts, Tennessee and Washington, were operated to capacity.

BUSINESS OPINIONS

Bradstreet's—Further marked extension of government control of production, of distribution and of labor, more urgent demands upon already full capacities for still greater efforts, some further shifting of the stream of war orders to western points from congested eastern areas, stimulation of fuel production in greater volume, a large, at some points, record volume of midsummer wholesale and jobbing distribution, fair to good retail buying, mail-order business in excess of 1917, improved collections, some shading of food crop estimates and a decided lowering of cotton condition due to drought in the southwest, a dull stock market, firm and even stringent money, high record bank clearings, close to low record failure totals, and a slightly quieter labor situation are the salient points in a week unusually full of important commercial and industrial happenings.

Dry Goods Economist—Cotton and cotton price fixing have engaged the attention of textile men this week to an unusual degree. The announcement in a prominent commercial paper of a percentage of 77.4 of the cotton crop on Wednesday was followed on Thursday by the Government's estimate of 73.6. The announcement of the Government's figures was followed by a raise in raw cotton on the New York Exchange of nearly 1c. per pound—or, as it is usually expressed, 95 points—in only a few moments. Analyzed, the figures mean that the estimate of Wednesday indicated a crop of 14,500,000 bales while the Government's estimate indicated one of 13,619,000 bales, both estimates being exclusive of linters which should be from 1,400,000 to 1,500,000 bales additional.

American Wool and Cotton Reporter—One favorable development in the wool market is the interest being taken in the purchasing of foreign wools, and in the regulation of the available supply. If agreements can be made and a satisfactory system devised it is possible that domestic manufacturers will be alloted a certain amount of wool which can be used for civilian purposes. The supply of wool seems sufficient, but limited by the existing shipping conditions, and possibly other causes.

Marshall Field & Co.—The wholesale distribution of dry goods for the current week is in excess of the large total of the corresponding week in 1917. Road sales, while light, are in excess of the same period of the previous year. Not quite as many customers have been in the market. Collections continue excellent, being larger than for the current week of last year.

Atlantic Seaboard

BOSTON

Average stocks in New England are but six weeks. Most buyers in cheerful mood, but situation hardly warrants it. Receipts

are maintained at July level. Railroad requirements to be handled from Washington. Wagon coal helps out the volume. Continued favorable shipments from Baltimore. Congestion at unloading berths here only temporary. Demand sags off for screenings. Anthracite receipts all-rail nearly up to quota, but disappointing at tidewater.

Bituminous—In well-informed trade circles there is an undercurrent of pessimism. Receipts have been favorable the past month and production has been maintained on an encouraging basis but this is a season of minimum consumption and maximum deliveries and our receipts should continue at their present level. No coal man in touch with the situation feels that this is possible for more than a few weeks longer.

The statistical section of the Fuel Administration at Washington regards its tabulation of receipts so complete that it is warranted in using it as an absolute guide. In other words, unless Washington has somehow found out that a plant exists not only is that plant not to receive coal but fuel for New England is to be allocated on the basis of such returns as have been made. Meanwhile, it is plain that heavy demands from over seas and from Government operations elsewhere will have to be met, and there is a turning toward New England as an area where a large tonnage can be spared. There is no shortage here of bituminous for current needs, but there is a serious shortage of storage coal which is usually accumulated during the summer months for winter use. Average stocks only cover about six weeks, and yet there are serious plans to divert coal from New England to requirements elsewhere.

The railroads, large utilities and the big textiles are far in arrears as compared with 1917 when, up to Aug. 23, coal was coming forward freely. If shipments to New England are now to be reduced instead of being built up, it will go hard with us next winter.

A large number of buyers were so influenced by the volume of coal that came forward in July that some are actually cautious about making purchases. There are plenty in New England today who are inclined to refuse coal. This, however, is no reason for the Fuel Administration to be shortsighted. Mr. Storrow made it plain at a conference in Washington last week that the situation would not permit any cutting of the allotment agreed upon last March.

At the five gateways receipts of bituminous thus far in August are about on the July level. The daily average for last month was 533 cars commercial and 153 cars railroad fuel or 686 cars in all. The number of box cars now being sent forward should increase during the next few weeks, although soon the enlarged demand for bunker and transport use will make itself felt keenly.

New England was depending upon increased receipts via the New York piers but obviously the prospect there is not hopeful. Plans of the usual distributors through ordinary trade channels have been considerably upset by the increased movement via Baltimore, thereby reducing the New England tonnage transshipped at New York. If now the Baltimore loadings for New England are also to be reduced there will be serious embarrassment.

Railroad requirements it is understood are to be handled directly from Washington, hereafter. This would seem like absent treatment, and already some of the results can be observed. Naturally the local fuel authorities are glad to be relieved of railroad requirements and to have the responsibility placed elsewhere, but this is hardly a prudent measure, as a matter of administration.

It is not known exactly to what extent wagon coal has been sent forward. Mr. Storrow's office saw to it that ample consignments were put on file and if the movement of coal in this equipment can be built up to 600 cars weekly it will be a distinct help especially to smaller plants and to retail dealers.

At Hampton Roads the coal available is sufficient to care for the bottoms that report and latterly there have been no serious cases of detention. It is probably only a matter of days when coal will be switched west and to the byproduct plants from which it was diverted a few weeks ago to relieve shortages at the piers. Aside from routine shipments on contract it is extremely difficult to arrange for cargoes.

Baltimore clearances still make a favorable showing for New England. Coal has been ordered to Curtis Bay to Mr. Storrow's order in considerable volume and steamers are regularly taking it on allocations furnished by him. Hampton Roads is thereby relieved, measurably, although a large tonnage of the coal ordered to Curtis Bay is diverted from shippers who would normally apply it to contracts via New York piers.

Some notice has been taken of delays in handling steamers at this end. Much of this is due to lack of berth room for ships bringing supply coal to the Boston & Maine R. R., a great effort having been made to send it in sufficient volume to give the needed reserve. Most of the delay has now been corrected, and where necessary the ships have been discharged at other berths for other consumers.

Anthracite—As a natural outcome of heavier shipments of bituminous the buying power for steam sizes has sagged to a marked degree. All-rail deliveries are still in large proportion, the July daily average having been in excess of 180 cars but there is decidedly less inquiry. Considering that the use of screenings and the buckwheats is new to most steam plants and the difficulty of getting improved stokers suited to the purpose, New England consumers show a good record in this respect. When bituminous shipments fall off again there will doubtless be a revived demand for steam anthracite.

The July average receipts all-rail of domestic sizes were well in excess of 600 cars. At Tidewater the movement is still slow and it is hard to see how the 1916 basic tonnage can possibly be caught up with for the coastwise towns even with the box cars that are being forwarded all-rail.

The whole question of distributing the increased quota seems much tangled and even recently there was no settled policy concerning it. Awkward questions such as the tonnage actually loaded aboard barges late in March, 1916, and sent to small towns where one cargo is a large proportion of a season's tonnage are not yet satisfactorily answered.

NEW YORK

Situation is easier, but apprehension continues. Anthracite dumpings increase, while bituminous decreases. Encouraging reports come from the mining regions. Bituminous moving freely but no opportunity for storing. Car supply in central Pennsylvania reported as slow. Complaint made of slow shipments.

Anthracite—The situation is easier but continues to occasion concern. Unfilled orders are much in excess of receipts and the trade fears that nothing short of a miracle can prevent a shortage of fuel next winter. Coal is moving easier and the cars dumped at the various local tidewater docks during the seven day period ended Aug. 2 show a substantial increase over the previous week.

State Fuel Administrator Cooke is getting the machinery of his office into working order and New York can expect to receive its full share of fuel now.

While the mine workers are doing everything within their power to maintain production, conferences have recently been held by representatives of the operators and mine workers at which methods to increase the output were discussed. The operators have also discussed among themselves further plans for the proper distribution of anthracite and they have agreed to follow all plans and suggestions that are likely to expand production, and have promised that if there are no further depletions of the labor forces, that dealers will get their orders filled by Nov. 1. Unless the Federal authorities step in it is likely that the army of mine workers will be further reduced 1000 in August when the next draft call is made, that number of mine workers being included in the call of men from Pennsylvania.

The migration of mine workers to other industries is expected to stop now because of the supervision of the labor situation by the Federal Employment Bureau. This bureau, it is expected, will prohibit war industries from combing the mining regions for men. Reports received here show that notwithstanding the labor difficulties, individual collieries are reporting record daily shipments.

Conditions in the district included in this market show some improvement. Coal is moving easier and dealers are slowly cleaning up their outstanding orders. In Manhattan Borough the retail dealers are optimistic. There is a heavy demand for both egg and stove, while chestnut and pea are easier. Efforts made to take care of the small outlying towns along the railroads are not so successful as it was hoped they would be. The residents of one town within commuting distance of New York complain that not all of the consumers there have yet received one-third of their requirements, although it is along the line of one of the largest coal-carrying roads.

The steam coals remain strong. Buckwheat No. 1 is practically out of the market, and few shippers have any to offer. Rice coal is also scarce. Barley and culm are much easier. Retail dealers are well stocked with these two sizes, but are short of bituminous to sell with them.

During July there were dumped at the New York Tidewater docks 31,284 cars of anthracite, as compared with 30,719 cars dumped in June, an increase of 565 cars. For the seven days ended Aug. 2 there were dumped 7609 cars as against 7054 cars, for the previous week, an increase of 555 cars.

Current quotations, per gross tons f.o.b., tidewater, at the lower ports, are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Pea	$5.20	$5.95
Egg	6.35	7.10	Buck	5.10	5.90
Stove	6.60	7.35	Rice	4.65	5.10
Chestnut	6.70	7.45	Barley	4.15	4.30
			Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—Although dumpings at the New York Tidewater docks for the past week fail to show any increase, conditions are easier. Coal is moving in better shape and consumers are able to get plenty for immediate needs but there is no surplus. There were dumped during the week ended Aug. 2, 6619 cars of bituminous as compared with 6922 cars during the previous seven days, a decrease of 303 cars. During July reports of the regional director of railroads show that 30,372 cars were dumped here as against 31,129 cars dumped in June, a decrease of 757 cars.

Reports of the Tidewater Coal Exchange show an increase in the number of cars of bituminous dumped for commercial and bunker purposes. Last month 30,745 cars of coal were dumped, as compared with 28,913 cars dumped in June; 27,929 cars dumped in May and 23,839 cars in April. The average daily number of cars discharged during the same period was Apr., 795 cars; May, 931 cars; June, 963 cars and July, 1138 cars.

Reports received here from the mining regions indicate a good car supply in West Virginia, with labor satisfied and willing to work to keep up production. In central Pennsylvania cars are reported as not up to requirements. Labor is short, but efforts are being made to keep up production. Representatives of the fuel administration are continually at work checking up the working time of each miner and asking those who seem to be lax to sign a card promising to do their best to keep up production.

Reports prepared by the Central Pennsylvania Coal Producers' Association show that there has already been a loss of 6.3 per cent. in the number of miners, loaders, cutters, and scrapers in central Pennsylvania and that if the draft boards continue to call to the colors the skilled employees about the mines, who are in Class 1 and those who registered on June 5 of this year, there will be a further depletion of 4.3 per cent.

There is much complaint of the failure of the railroad companies to pay their bills promptly.

Bunker coal is moving quickly and shipping is not delayed. In connection with the formation of the new pools Nos. 71 and 72, it has been announced that all coals in the former Pool No. 9 in classifications "C" and "D" are changed to Pool No. 71 when the coal is used for bunkering purposes. Producers shipping their coals to Pool No. 10 have been allowed the privilege of shipping to Pool No. 72 when the coal is consigned for bunkers. When coal is shipped for commercial purposes Pool No. 10 applies.

This market is comparatively clear of free coals, nearly all of the shipments coming here being for regular customers.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite situation unchanged. Egg coal grows easier. Full deliveries allowed. Pea coal somewhat freer. Stove and nut tight as ever. Buckwheat piling up in retail yards. Dealers compile more information. Steam stocks accumulate. Tide shipments rerouted. Bituminous car supply hit by change in rating. Fair shipments received.

Anthracite. The general situation continues without marked change. The dealers are in distress, due chiefly to the shortage of stove and chestnut. Whenever any stock of coal can be found it is without exception egg. Most of the yards are empty because the coal received is invariably delivered too promptly to allow any accumulation. Philadelphia proper has always been a poor market for egg coal and some dealers have already delivered the full two-thirds of all the orders they hold for this size. This week some dealers had been given permission to complete their orders calling for egg coal. It was an easy matter to convince the authorities that there was no wisdom in allowing their trucks to stand idle while they had coal in their yards and a place to put it. This condition is not general, for in the suburbs where the demand for egg is always heavy the dealers are still begging for it.

Pea coal, too, is not as scarce as it was and at least one large company reports being comparatively easy on it. The great demand for pea coal never comes until cold weather. On account of its price it has always been in great demand in the small homes. In other years the spring reduction never affected pea size, and the consumers as a whole have not as yet been educated to store it. There will be an active demand for this coal before the year is out and dealers are anxious to secure every possible car of it.

One firm reports a peculiar situation on No. 1 buckwheat. It has an oversupply and many of its steam-coal buyers are pleading for it. The fuel authorities are unwilling to have more than one day's supply furnished at a time to this trade. In the meantime the coal is piling up in the retail yards. While the dealers are anxious to use their equipment and store the coal in their customers' bins for next fall and winter use, the fuel people seem to think it the better policy to hold it in case of a shortage of the domestic sizes at that time, when it could be used as a substitute.

This week the dealers received another request for information from the local fuel authorities. They must advise promptly the number of tons of family coal they delivered during July; the number of tons on hand, and the number of tons of prepared sizes for which they have unfilled orders. In the letters they are advised that the information desired is most important, "particularly to learn how much coal is necessary to bring into Philadelphia during the next 60 days to take care of unfilled orders." To the uninitiated this would appear encouraging, and while the dealers will furnish the desired figures, they are none too optimistic of much help resulting.

While the dealers still appear anxious over the general situation there continues to be a note of optimism among the authorities, who feel they have the situation well in hand. A recent move that will help the local situation is the decision of the army authorities to use nothing but bituminous coal in the Southern army cantonments. This, of course, will release a heavy tonnage for the strictly anthracite domestic territory.

The lightless night plan is now in full working order, although it has been modified somewhat as to the curtailment of street lighting, in that it was found advisable to allow the use of more lights than was first thought necessary. There was also one prosecution of a store owner for violating the rule against show-window lighting.

All the shipping companies this week were checked up by the authorities on their shipments of gas coal to the New England territory, and those who had fallen behind the allotment of broken coal were directed to make it up at once.

The new ruling of the railroad administration requiring spot payment for freight did not appear to ruffle the retailers in the least. It did, however, have a tendency to cause the dealers to make their credit plans stricter than ever.

In the steam trade the demand does not diminish. There is no free coal of any size except culm to be had. Heavy shipments of this size continue to New England—so heavy, in fact, that some speculation is aroused as to whether it is not being overdone. Old-time users of buckwheat in this market, especially those on war work, are accumulating heavy stocks of this coal. Good tide shipments have also been resumed. A plan to expedite the movement of tide coal has just been put in force whereby a saving in time of 36 to 48 hr. is effected. This has been accomplished by rerouting coal via the Pennsylvania R. R. Schuylkill Division, where practically all passenger traffic has been withdrawn.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—The shippers of bituminous coal have been greatly upset by the change in the car allotment as adopted by the Pennsylvania R. R. in central Pennsylvania. Here they have gone back to the old system of rating based on the number of working places in the mines. As a consequence may mines have had far from sufficient cars, while others have had more than they can load. On the whole the average has been 60 per cent.

This change seems unfortunate just at a time when things had begun to run smoothly and a record tonnage was being gotten out. So far local industries have not suffered for want of fuel, although the storage plans of many have been upset inasmuch as they have received far below the average they have been getting for the past several weeks.

BALTIMORE

Strong appeals for relief in short bituminous situation here met by promise of 60 cars of soft coal for most urgent needs. Hard coal men preparing figures to demonstrate need of greater shipments.

Bituminous—While a fairly good tonnage of soft coal has been moving into the Baltimore district as viewed from the standpoint of railroad figures, the major part has been definitely destined for the use of war industries and shipping account, and some urgent industrial needs here have been neglected.

Slowly but surely the request list for first shipments as prepared by the Maryland Fuel Administration and forwarded to the district representative at Cumberland has grown beyond the shipments on that account. For several weeks the demands of the canners have piled up as the packing industry found that it could not get the coal it had contracted for.

The appeals of the state fuel administrator to the district representative were not met, and finally the local fuel administration put the case up to the national fuel body. It was pointed out that great losses of the fruit and vegetable pack had already taken place or were threatened, and on Wednesday, after days of delay, a promise came of 60 cars to be diverted to the fuel administrator here for the packing and other emergency business needs.

Many industries here are at present living practically from hand to mouth, and all thought of stocking up by other than war-preferential industries during the summer has been abandoned. Some of the preferential plants have a three months' supply or more on hand and are now getting regular shipments. It is thus only the non-preferred branches of business that suffer for the time while heavy movements of soft coal are forwarded to New England and the Northwest. That all coal wanted preferentially does not always come through has been demonstrated recently several times when vessels have been held to await finishing of cargo. A number of these were preferential loadings for the account of Starrow, of New England.

Anthracite—With monthly deliveries of hard coal falling behid past years' averages, the anthracite dealers are spending much time in figuring. It had been hoped to deliver two thirds of all orders before October, but this is now practically despaired of in view of the fact that the monthly receipts here are less than 60,000 tons, while there is 300,000 tons estimated still on the books of dealers undelivered and a considerable amount of orders applying for addition to that list.

In order to get down to "brass-tacks" so to speak the Baltimore Coal Exchange has asked all hard coal dealers to file reports of receipts of fuel so far since April 1, amounts of deliveries to customers, amounts still on the order books, estimates of business to come from old customers, promises of delivery from mine connections, etc., in order that a general estimate of needs of Baltimore can be prepared. With these facts the trade expects to be able to give the consuming public the information which it desires, and at the same time be prepared to appear before the fuel administration and urge additional shipment. War industries are eating deeper and deeper into the hard coal apportionment here, and this complicates the situation.

Lake Markets

PITTSBURGH

Heavy Lake shipments are under the mark. Four mines closed for shipping dirty coal. Regulations for wagon mines.

Shipments of Lake coal in July from the Pittsburgh district are estimated to have exceeded only slightly the original quota of 1,300,000 tons, although an effort was made to exceed that amount by as large a quantity as possible. Stocking of rail coal has been under ban since early in July. A few consumers, who are not on the preference list, have been cut off from supplies.

R. W. Gardiner, fuel distributor for the district, has closed four mines on account of their shipping dirty coal. These mines will open when inspectors are detailed to indicate precisely what coal shall be mined and what left. While the number of inspectors is not sufficient as yet to make periodic inspections of coal as shipped it is believed the closing of some offending mines will have a salutary effect upon others and thus secure a general improvement.

The local fuel administration has prescribed prices for wagon mines with a view to encouraging their operation. Manufacturers or large consumers making blanket contracts to take the entire daily output of the mine are given a maximum price of $2.45 or 10c. above the standard price. Hospitals, office buildings and the like are given a price up to $2.75, while to domestic consumers the price is set at $3 maximum, all these prices being at the mine platform. Haulage charges in addition are prescribed, 70c. per ton for the first mile or fraction, up to $2.15 for between 7 and 8 miles.

Essential consumers are being well supplied with rail coal according to their requirements and there is some stocking of truck and river coal. Transactions in the open market are light, it being difficult to secure coal except through action by the authorities. Prices remain: Slack, $2.15; mine run, $2.35; lump, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to be charged in addition by brokers.

BUFFALO

Market tranquil, considering former unsettled conditions. Canadian trade quiet, especially bituminous. Much low-grade anthracite sold there. Lake shipments fair.

Bituminous—The supply would be sufficient but for the resumption of late of preferential orders, sending coal to points out of the regular course and leaving consumers short when they thought they had plenty. While these orders come from a larger survey of the situation than the local shipper is able to make they disturb the trade badly sometimes. Orders of coal to New England do not have a quieting sound and it is hoped that they will not be as numerous as they were last year.

At least one local shipper is taking the view of the case that tends to reduce the general feeling of uneasiness to the minimum. He finds that Canada has a good supply of bituminous and that Buffalo and New York state are pretty well taken care of. This means that a good many consumers have stocked up well and in Canada the good supply of bituminous has enabled consumers to buy it as a substitute for anthracite. This has also been done to some extent in this state.

The tendency to accept anything that looks like coal is said to have enabled many small producers of anthracite to ship into Canada what is called mine run, which is said not to have been picked over at all, but is full of impurities and sometimes so poor in quality that nobody will buy it. It was said that the authorities were preparing to stop the shipping of such coal, but some still appears to escape the inspectors.

Jobbers are not gaining much on their trade. They find it hard to get any coal and the prospect is not good for a larger surplus. All the average jobber can now hope to do is to keep along, meet expenses and be in readiness for trade resumption.

Bituminous prices are still hard to figure out, but the average jobber makes them out to be $4.65 for thin-vein Allegheny Valley, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine run and slack, $5.85 for smithing and $6.20 for cannel, though cannel differs somewhat as to the region it comes from; all prices f.o.b. Buffalo with jobber's profit added.

Anthracite—The movement westward is not heavy. The city demand is active and it will continue so till the last cellar is well supplied, which is not likely to take place this season, and some will do well if they get a supply in any quantity during the winter. At the same time it is not believed that any severe shortage will occur. It is not expected to provide a large amount for consumers to carry several months, but all legitimate needs will be met.

The shipments by Lake are not equal to last season, but are of fair amount, being for the week 95,800 tons, of which 15,900 tons cleared for Chicago, 28,900 tons for Milwaukee, 7500 tons for Waukegan, 7300 tons for Green Bay, 600 tons for Mackinaw, 3500 tons for Ashland and 8000 tons for Port Arthur.

CLEVELAND

Bituminous shipments have decreased, due both to a reduced car supply in southern Ohio and to a more extensive diversion of coal to the Great Lakes. Lake shipments for the past week have been at the rate of 1,100,000 tons. The close of July, however, sees shipments 999,906 tons behind the Fuel Administration's schedule.

Bituminous—Receipts of soft coal during the past week have decreased somewhat. In accordance with the Fuel Administration's speeding-up plan for Lake shipments, and due partially to a lower car supply, the bituminous available for industrial and domestic consumers has fallen short of requirements.

Industrial stocking may virtually be said to be at an end. Retail dealers are considerably deferred on orders, though it is declared that the amount of coal householders have laid in for next winter is large. It is estimated that more than 50 per cent of the domestic coal that will be consumed in Cleveland next winter already has been stored. Some northern Ohio cities are reported to have more than 90 per cent. of their coal requirements already in.

The car supply in the No. 8 district has fallen off somewhat in the past week, though not to the extent production has suffered. Car supply and available labor have just about balanced.

No shading of the government maximum prices on bituminous coal is reported in this territory, nor is contracting flourishing even though the Fuel Administration has lifted the ban on contracts running longer than one year.

Operators here would not be surprised to see a fair amount of Ohio coal go east into Pennsylvania after the Lake season ends in order to release more Pennsylvania coal for New England.

Anthracite—On account of the zoning system practically no anthracite is coming through to this territory.

Lake Trade—July figures on bituminous shipments to the Northwest, which have just been announced, place the movement at 4,038.795 tons, as against the 4,900,000 tons called for by the schedule of the Fuel Administration. This puts the lake trade exactly 999,906 tons behind the schedule up to Aug. 1. However, at the rate coal has been moving the past week this is only one week's tardiness.

The following are detailed figures on the Lake movement to July 15—no comparisons up to Aug. 1 yet being available—which have been prepared by the Coal and Ore Exchange, of Cleveland, which is in charge of the lake pool this season:

	1918	1917	1918 Ahead of 1917	1918 Compared with Schedule
To April 30th..	861,157	651,479	209,678	—638,843
May....	2,970,326	2,428,118	542,208	+470,326
June....	3,429,716	3,250,149	179,567	+29,716
To July 15th..	1,791,320	1,780,409	10,911	—470,680
Total to July 15	9,052,519	8,110,155	942,364	—609,481

DETROIT

Distribution of coal to domestic consumers is still being retarded by scarcity of stock. Lake shipments are being increased.

Bituminous—With receipts of bituminous made up chiefly of mine run, local jobbers complain that it is not easy to get coal that is acceptable to household consumers. The incoming shipments, it is said, include little domestic lump or other prepared sizes. As most of the domestic buyers, who heretofore have used anthracite have been holding off through the earlier months of the year in the hope of getting their favorite fuel, the distribution of next winter's supply is not what it should be at this season of the year and is being further retarded by scarcity of supply, dealers say, since the date when regulations of the state fuel administrator made it clear that many former anthracite users must substitute bituminous this year.

Steam coal users are actively in the market for stock. Their requirements for present needs absorb practically all the coal reaching the city, the small excess going to help increase reserves of those of the larger concerns which have suitable space for storage. In many instances steam coal users, who in the past have been satisfied with day to day shipments, are attempting to accumulate a supply and are providing themselves with storage of somewhat limited capacity.

Anthracite—Some of the retailers find indications of a slight improvement in quantity of anthracite arriving, though the amount remains so small that not much progress can be made in deliveries. The special committee appointed by the Detroit Board of Commerce to call on the federal fuel administrator and seek an increase in the allotment of anthracite to Michigan and Detroit, is being increased by the addition of out-of-town business men. It is asserted that the importance of the work Detroit is performing for the government and the necessity of keeping labor in this city demand further relief, at least to the extent of making good with anthracite the 600,000 tons of smokeless and coke taken from Detroit domestic consumers.

Lake Trade—Lake shipments during last week were approximately 1,000,000 tons, having been the heaviest for several weeks. Instructions have been issued to mines to concentrate on shipments to the lakes and August is expected to far exceed the movement in July.

COLUMBUS

The diverting of a large tonnage to the Lake trade has caused a scarcity in domestic trade in certain localities. Domestic demand is still good and there is also a good trade in steam sizes. The tone of the trade is generally satisfactory.

Domestic demand is now attracting considerable attention in Ohio because of the recent ruling which diverts a larger proportion of the coal to the Lakes. Already retailers are asking for tonnage as their surplus stocks are generally small. The domestic demand is fairly active, although dealers have not the volume of business on their books as was the case several months ago. All teams and trucks are kept busy, however.

A large part of the coal in the yards is now mine-run, which is being accepted by most private users without complaint. Pocahontas is scarce and only mine-run is arriving. There are still some West Virginia splints on the local market. But the main bulk comes from Ohio mines. Retail prices are firm at the levels which have prevailed for some time. New freight rates are being worked out and still higher advances are expected.

The Lake trade is one of the busy departments of the industry. Lake shippers are exerting every effort to get a large tonnage to the Northwest. The deficiency caused by the late opening is being gradually made up, but there is still a marked shortage. The vessel movement is active as is that of coal off the docks of the upper Lake ports and no congestion is reported.

The steam trade is also active, as steam users are trying to accumulate a surplus. Their efforts have only met with partial success. The public service concerns have succeeded in laying in a fair surplus. Schools are mostly provided for and public institutions are now being looked after. There is still a considerable tonnage of screenings coming into the local market because of the activity in the Lake trade.

Production is active in all of the Ohio producing fields. The car supply has been better, amounting to practically 100 per cent. in all districts. On the whole the output of the Hocking Valley and Pomeroy Bend districts has been close to 90 per cent. and in other fields it has ranged from 80 to 90 per cent. of normal.

CINCINNATI

Increasing demands of East, tending to cut down local supply, are causing some worry among the trade. Domestic situation is good, but manufacturers are uneasy.

A factor which, it is declared both by operators and local fuel authorities, will be of increasing importance as the season advances, is the necessary diversion of much West Virginia coal which formerly came to Cincinnati and the Middle West to the East, to take care of the enormous needs of the seaboard, especially in the manufacturing centers. It is generally conceded that the inability of the industry to meet the high production figures set by the National Fuel Administration, and the consequent shortage in the amount of coal available for the East from its usual sources, make it unavoidable to divert to that section some coal which normally goes elsewhere; but, at the same time, the diversion of so large a proportion of the fuel relied upon by the great manufacturing districts of the Middle West is viewed with considerable concern, especially as there is at present no immediate prospect of finding a satisfactory volume of coal with which to supply the deficiency.

While the eastern Kentucky field, with large supplies of first-class coal, is virtually at the door of this market, and much of its fuel passes through the Cincinnati gateway bound to the Lakes and Northern points generally, it is stated by those in touch with the situation that much, if not all of it, is already contracted for, making it unavailable at this time to meet the emergency created by the diversion of the West Virginia product. The suggestion that Ohio and other parts of the Middle West may use Ohio, Indiana and western Kentucky coal meets with the same objection, aside from the fact that some of this fuel is much inferior to that for which it is proposed as a substitute.

The demands of the Lake movement are being met as usual just now, the volume of traffic being extremely heavy; and while there is, under the circumstances, comparatively little coal available for storage by local manufacturers, it is still felt that as long as domestic consumers are covered as well as they now are, the fuel which will be available when the Lake movement ceases, plus that which can be stored in the meantime, will meet the situation.

LOUISVILLE

General demand for all grades of coal continues strong, with supplies light. Car supply growing more acute. Retailers unable to secure enough coal to take care of domestic trade, much less build up, hard stocks.

There has been absolutely no let-up in the general demand for all grades of coal. Everything is selling as quickly as it can be had, although there is little stocking demand for western Kentucky nut and slack, as a number of large consumers have had bad experiences this season with such coal firing. During the last week of July several fires were going in local stocks simultaneously. No trouble of this kind has been reported from domestic consumers, many of whom have taken nut and slack.

General tightening up of credits has made it somewhat harder for the domestic consumer to secure coal this season. At the present time one concern is quoting 60 days' credit to old customers, and 30 days to new ones. Many others are quoting 30 days to old customers and cash to all new ones, while several houses are refusing to handle anything other than cash business. No orders are being delivered where the customer hasn't paid off his 1917-18 bill completely. In some cases dealers are accepting season orders with provisions that they will make deliveries of one and two ton lots as the consumer can pay for it, and take care of such orders before other rush business later on, but on the basis of the market price at time of delivery.

In eastern Kentucky it is reported that more coal is now moving into the North and South Carolina district than usual. Much of the coal from the Clinchfield region has been delivered by orders of the Fuel Administration, and rates over the Louisville & Nashville have been made which enable eastern Kentucky coal to go to the textile mills, and cotton oil concerns. Some coal is also going to Southern ports for export, but a large portion of the production is going to the lake district and to the coal byproducts plants.

Wagon mines of the state are now being forced to load in box cars entirely, and all open cars and gondolas are being supplied to the tipple mines. However, even box cars are scarce, and all classes of mines have been having trouble in securing cars during the past ten days, due partly to the fact that hauls into the Lake District are keeping cars on the road for long intervals, and returns are slow.

BIRMINGHAM

Trade conditions without material change, demand continuing strong for both domestic and steam product. Production gaining slowly. Labor working more steadily, with slight increase in working forces. Shortage of equipment for loading reported in some instances.

Alabama is making slow but steady strides in the production of coal, the output for the week ending July 20 reaching the highest figure of record for this district. Figures in the hands of the district representative of the fuel administration not yet compiled, indicate that the week ending July 27 showed a slight gain over the previous period. This is accounted for by steadier work on the part of the miners and some increase in the working forces.

The steam coal demand is steady, but the gain in production has not been sufficient as yet to noticeably affect the supply in contrast with requirements. The railroads continue to draw heavily on the output of commercial mines, the Southern having increased the percentage of its priority order for the present week. However, due to adjustments made in the rating of production at some of the mines, the additional tonnage to be taken is not large.

Wholesale and retail trade in domestic sizes is stiff, and consumers are stocking as rapidly as the supply will admit. Receipts by dealers would be satisfactory under normal trade conditions at this season of the year, but the propaganda of the fuel administration urging that winter coal be

laid in without delay has been 100 per cent. effective here and retail yards are kept barren of stocks.

Short delays have been experienced at some mines on account of equipment not being available for loading, but this has not crippled production materially.

Coke

CONNELLSVILLE

Set price on coke from dumps. Working conditions improved. Foundries evidently stocking.

The working over of old dumps at coke works has increased to such an extent that the Fuel Administration has fixed a price on the material, when it is cleaned and otherwise prepared, but not sized, the price being $1 under the foundry coke price, which makes it $6 in the case of Connellsville. Crushed coke, fixed long ago at $7.30 for sizes over 1-in., the screen being recently changed to ¾-in., is assumed by the trade to include these old screenings also, if they are sized, coke under ¾-in. being by regulation $1 under blast furnace coke, or $5 in the case of Connellsville. Coke breeze was recently fixed at half the blast furnace coke price, which makes $3 for Connellsville.

An excellent trade has been developed for the material obtained from old dumps and the market for the best material has been quite clearly defined for several weeks past at $6.50. Those who are producing the material will be disposed to make sure that it comes under the Fuel Administration regulations as to size, for otherwise they could charge only $6. On account of improvement in labor conditions several operators have within the past ten days announced their intention of going into this screening business. Previously they had been indisposed to do so by reason of not being able to spare the labor.

Working conditions generally throughout the region have improved, not through the accretion of men but through their putting in fuller time, as a result of the strenuous propaganda of the operators and of some Government activities. What concerns operators now is the prospective extension of the draft age limits, and the operators intend to see to it that the local and district draft boards impress upon registrants, to the extent permitted by Washington, the importance of remaining at preferred occupations.

The idea was entertained a few weeks ago that by this time coke would be visibly plentiful in the market and the possibility was considered of there being enough coke offered to depress prices. Since then production has increased by about 10,000 tons a week and yet there is not only no appearance of coke being plentiful, but there is practically no furnace coke offered in the market. The trade is seeking a reason for the condition and finds it in the stocking of coke by consumers. Blast furnaces do not admit that they are stocking coke to any extent but it is believed that many are doing so in a limited way.

Offerings of foundry coke continue relatively heavy, and all is absorbed. There is reason to believe that many foundries are stocking coke quite freely, prompted by the extremely scant supplies of last winter. Of the total make a proportion can be offered as foundry coke much in excess of the normal consumption of foundry coke. In times past foundry coke had to meet three requirements, among others, 72 hr. burning, careful selection, and shipment in box cars. Box cars having largely disappeared, that requirement is out of the way, and as to selection there is no definite rule. As to 72-hr. burning, the system of working always produces a large proportion of such coke. The market is quotable at the set limits of $6 and $7 respectively for furnace and 72-hr. foundry, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended July 27 at 352,625 tons, an increase of 975 tons.

Buffalo—This territory rejoices that it has two large byproduct coke plants, but for which the supply might run short. A third plant is in process of construction, but it will not be ready for use this season. The output that is not turned out here is bought in the Connellsville district at Government prices. It is not always easy to obtain a supply, but the furnaces continue to run practically on full time. Jobbers sell a moderate amount of breeze only. The Lake receipts of iron ore for the week were 336,350 gross tons, which is quite up to the season's average.

Middle Western

GENERAL REVIEW

Situation good. Car supply almost perfect. Labor conditions better. Market holding up well to Government price. Railroads are heavy buyers. Eastern coal arrives in substantial amounts.

The coal situation in the mid-western territory is good. All the larger coal-carrying railroads, with the exception of the Wabash, report nearly a perfect car supply in their respective coal producing territories. Evidently there is also some improvement in the labor supply because early reports show that the tonnage for the week will perhaps equal, if not exceed, the records recently established. The outlook on transportation and labor is better than it has been for some time.

Market conditions remain without any radical or serious change. All the high-grade fuels, both steam and domestic, are holding firm on a basis of "Government price current at time of shipment." Some of the poorer-grade coals, however, from both Indiana and Illinois, are selling below the prices as set by the Government, but this only applies to steam sizes, as the demand for domestic coal is keeping up as steady as ever.

The railroads are buying a big tonnage, both for their current needs and for storage purposes. This, coupled with the large order placed a little while ago by the Government for its various training camps, etc., has brought about no apparent shortage. This augurs well for any tonnage that might be expected from this territory.

Eastern coal continues to arrive in this market in substantial lots. This is especially true of the Lower Lake ports. It is said, however, that there is a temporary shortage at Duluth, but to counteract this there is a big tonnage of Lake coal at Chicago. Last year one of the railroads with dock connections handled during the first 25 days of July 4764 cars of Lake coal. For the same period this year its figures show 5673 cars, or almost a 25 per cent. increase.

In short, today the coal situation, both from the standpoint of the producer and the consumer, is better than it has been for some time.

MILWAUKEE

Schedule of prices for anthracite finally announced. Small dealers claim to be at a disadvantage. Liberal receipts of hard coal during the week.

Coal consumers in the Milwaukee district are now able to figure the cost of their anthracite supply for the coming winter, as the scale of prices for anthracite has been made known. Chestnut, delivered at the curb, is now $11.30 per ton, stove $11.20, egg $11 and buckwheat $9.75. The usual charge of 50c. per ton applies where coal is carried in. All anthracite delivered between June 1 and July 27, when the new rates were made effective, must be billed 40c. under the above schedule. If the Fuel Administration enforces the ruling made early in the season, when the usual advance of 10c. per ton per month during the summer was discontinued, an addition of 30c. per ton will automatically apply on the first of September.

The soft coal schedule continues as follows: Pittsburgh, Youghiogheny and Hocking lump $6.80, pile run $6.55 and screenings $6.30; West Virginia splint lump $7.30, pile run $7.05 and screenings $6.80; Kanawha gas lump and egg $8.05, pile run $7.05 and screenings $6.80. The carrying-in charge of 50c. per ton applies to soft coal also.

Three cargoes of anthracite aggregating 36,672 tons, were docked since last week's report. A correction in the July report shifted 7,300 tons from the hard coal column to the bituminous total. The record of cargoes by Lake now stands:

	Hard	Soft
May	85,700	389,547
June	53,947	434,094
July	*99,616	*532,719
Total	239,263	1,356,360

*Subject to slight revision.

Last year's record, including receipts by carferry, which are not embraced in the above figures for 1918, was: Hard coal, 257,643 tons; soft coal, 1,266,644.

ST. LOUIS

Market is rather easy in a general way on practically everything. Steam is slow and domestic is letting up, excepting on Carterville. Country demand easier. Car supply poor, and unequally distributed. In a general way conditions are satisfactory.

The local situation is easy and there is not the demand that might be expected, and such as exists in other cities of this size.

The steam trade seems to be taking things rather easy and not giving much thought to the future. A recent survey made by the Manufacturers' Association shows that there is practically no storage coal in St. Louis for manufacturing purposes and the manufacturers seem to think that there is no need for any worrying, while the coal operators and the Fuel Administration are striving to prevent any serious shortage this coming winter by persuading users to store coal now. This has been brought about by the fact that there has been a surplus for the past few months and many consumers think that this is going to continue.

The domestic demand has been off for the last week and this will likely continue for the next month or longer, as far as Mt. Olive and Standard coals are concerned.

The shortage of Carterville continues and the demand cannot be met. There will be no change in this situation even though there may be a little more Carterville coming in than is expected now. It will be impossible to supply the Carterville demand.

The country business, which has been good up to the present, is letting up some and this has a tendency to throw an additional tonnage on the local market.

St. Louis is without question the best coaled city in the country today among the larger cities as far as domestic tonnage is concerned. The figures turned in by the retailers on Aug. 1 have not been totalled, but will show an enormous tonnage of storage coal.

Conditions in the fields seem to run about the same week after week. In the Carterville field cars have been a trifle better this week and a little more domestic tonnage has come through. Labor conditions are still poor and show little improvement.

The Fuel Administration has ordered that the Johnston City Coal Co. and the Searles Coal Co., both of Johnston City, discontinue shipping railroad fuel, and this throws a minimum of about 4,000 tons a week on the market. Other mines have had their railroad tonnage reduced, so that there will be more domestic coal from this field.

In the Duquoin field conditions are much the same as in the Carterville, with the railroads getting considerable tonnage.

The Mt. Olive field is the quiet, easy-going section of southern Illinois, with a supply that takes care of the demand, a fairly good car supply, good movement, and in a general way satisfactory conditions.

The Standard situation is still a problem. Some mines continue to get all the equipment they can handle and others get in only two or three days a week. This is causing considerable unrest among the miners, as they keep moving about from one mine to another.

Screenings are long and the market is not available for the tonnage produced, but if the railroad tonnage is cut down in the Carterville field it will force a greater tonnage from this district, which will take care of the surplus screenings. The market on this coal has been off some, but is commencing to come up to the Government maximum.

Two-inch lump is quoted around $2.45 and $2.50, while egg and nut and other lump sizes go at $2.55. Mine-run is selling at $2.25 and screenings at about $1.70.

There are no Eastern coals and a very large tonnage of Arkansas coming in.

The Government maximum price is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....
No. 3 nut	2.55@2.70	2.55@2.70	.....
No. 4 nut	2.55@2.70	2.55@2.70	.....
No. 5 nut	2.05@2.20	2.05@2.20	.....
2-in. scrgs	2.05@2.20	2.05@2.20	1.25@1.50
3-in. lump	.....	.....	2.25@2.40
2-in. lump	.....	.....	2.25@2.40
Steam egg	.....	.....	2.25@2.40
Mine run	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1	2.75@2.90	2.75@2.90	.....
No. 2	2.75@2.90	2.75@2.90	.....
No. 3	2.55@2.75	2.55@2.75	.....
No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

COAL AGE

Volume 14 New York, August 15, 1918 Number 7

Intemperance Hampers Production

By R. Dawson Hall

NO ONE will be disposed to criticize the defense of the mine worker's sobriety recently made by President Hayes, of the United Mine Workers of America. He was probably justified in believing that the worker in the coal mine is no more prone to alcoholism than the men in some other industries. At least, all in the industry desire to believe that this is true.

Nevertheless the chart we publish this week on page 302 shows that every pay day is followed by a period of absenteeism as distressing as it is needless. The chart represents conditions at 6 anthracite collieries and so exhibits the absenteeism of just one-sixtieth part of the whole anthracite region.

It is said that the loss of coal from the man shortage thus caused aggregates 5000 tons a month at the 6 collieries. It would therefore be permissible to figure the loss for the whole anthracite region at 4,000,000 tons a year. Those who have investigated the situation say that the cause of the idleness is the saloon and that the saloon is attracting more men than ever.

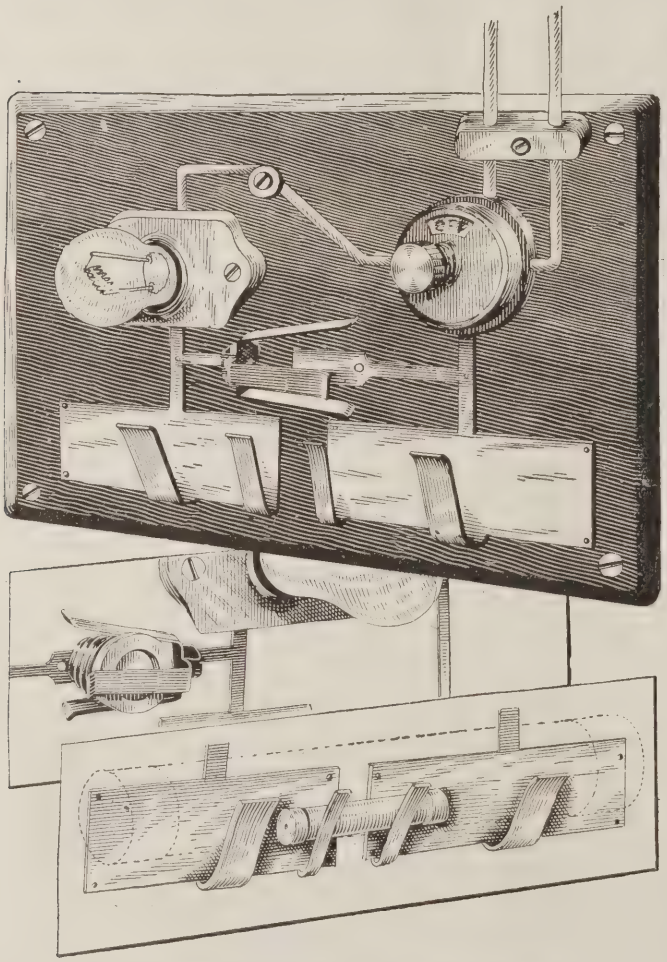
On the first day after pay day at the close of last month 240 men were absent from the 6 collieries mentioned and on the day following there were 175 men still absent. Whereas 9300 tons were mined on pay day only 6200 tons were mined on the day following. On one occasion a policeman counted 116 men in the Wilkes-Barre saloons between 8:30 and 11:30 p.m. At one saloon there were 20 men still drinking at 4 a.m.

The conditions shown in the chart exist at mines which are considered leaders in the matter of good management. It is probable that drunkenness is not as rife in these mines as in others, for an attempt has always been made to hire desirable men who were known to work with reasonable steadiness. Just lately, however, managers are hiring all who come without asking questions and there is no attempt to exclude men who are known to be of uncertain habits.

The uncertainty in the daily output naturally ties up many railroad cars. If the operators could know just how many men would work each day, the car supply could be exactly adjusted to needs. As it is, many idle cars have to be carried over whenever men are absent.

If the saloons are to be allowed to ply their trade during the war why not close them between 9 p.m. and 8 a.m.? The mine workers and other workingmen can then get their drink of beer on returning from work, but cannot extend their potations to too late an hour and cannot renew them in the morning before going to their hazardous work. Should this not succeed a more drastic provision could be put into force.

In whatever is done the mine worker should coöperate. The loyal, sober, hard-working patriot predominates in the industry, and he is so strongly opposed to disloyalty, insobriety or slacking that he is sensitive if the charge is wrongly applied to the industry as a whole. Yet he knows well that there are such elements working in the coal mines and with a little urging there is nothing he will not do to root them out.



IDEAS AND SUGGESTIONS

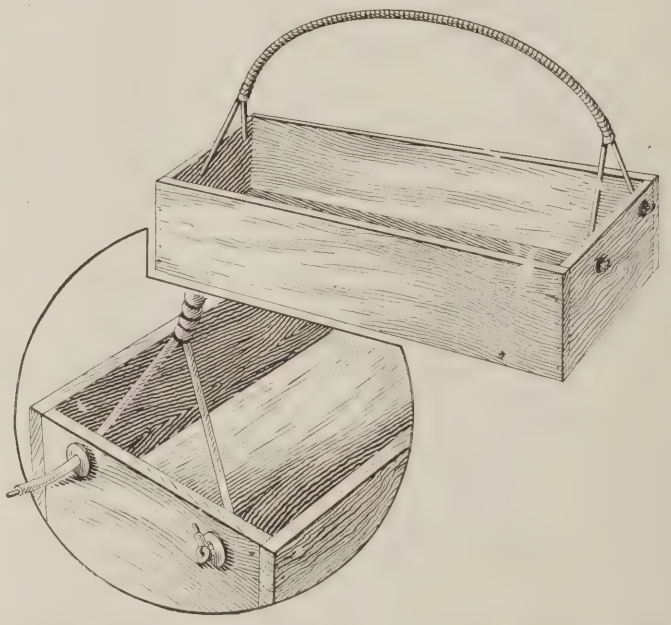
A Convenient Fuse Tester

BY L. V. LAUTHER
Guttenberg, N. J

The accompanying illustration shows a device for testing electric fuses. As I had a great many such fuses to test daily I hit upon this scheme to facilitate the work.

The tester, as may be seen, consists of a few properly shaped and formed metal strips and two electrical

THE APPARATUS FOR TESTING FUSES



fittings that may be easily procured at almost any mine. The whole apparatus is mounted on a piece of slate that may be sawed from a broken or discarded switchboard. The edges of this piece may be cut away on a bevel if desired.

A single-throw double-pole switch puts current onto the board. If the fuse being tested is in proper shape the light will burn. The illustrations show that a similar arrangement may be employed with equal ease for testing either long or short cartridge fuses as well as those of the socket variety.

Handy Non-Tipping Tool Tray

A common method of making a tool tray or hand tool box is to nail a strap or piece of old belt across the open top of a box. This arrangement is liable to tilt sidewise, allowing the tools to fall out.

The accompanying illustration shows a tool tray of similar character and purpose to the one just described, but so built as to avoid side tipping. The bail, or handle, of this tray is made from a short length of armored two-conductor cable. The armoring is cut away from this cable for a suitable distance at the ends, exposing the two conductors. These are spread apart and each passed through a small hole drilled in

FINISHED TRAY AND DETAILS OF CONSTRUCTION

the end or side of the box. Over the end of the conductor a burr or washer is slipped.

This may either be soldered in the proper position or a knot tied in the conductor resting against the washer. A bail is thus formed that is semi-flexible yet prevents tipping of the box when lifted or held in the hand.

Undercutting or Slotting of Commutators

BY FRANK HUSKINSON
Lafayette, Colo.

It is believed by many that slotting or cutting out the mica between commutator segments is or should be a sure cure for commutator troubles. A few do not believe in undercutting the commutator at all. As a matter of fact, undercutting relieves certain troubles and is to be recommended for all types of mine-loco-

motive armatures. In most cases, also, it is well to undercut the commutators of the motors of mining machines, pumps and stationary motors in general.

Several factors should be taken into account when the undercutting of mica is being considered. The most important of these are the conditions of operation, frequency of inspection and the peripheral speed. Slots that have been undercut are liable to fill up with dust, dirt and oil. This is especially true if the motor is located in a dusty or dirty place. If the machine is of the open type, care should be taken to see that there is no possibility of oil dripping on the commutator; for oil, dust and a few particles of carbon from the brushes and copper from the commutator itself will fill the slots with a conducting composition that will sooner or later cause such trouble as short-circuits between the bars, flash-overs and the like.

A machine that has the commutator undercut should have frequent inspection, as there is a chance of small particles of copper, carbon and other foreign substances lodging between the bars. Such accumulations should be brushed out at frequent intervals.

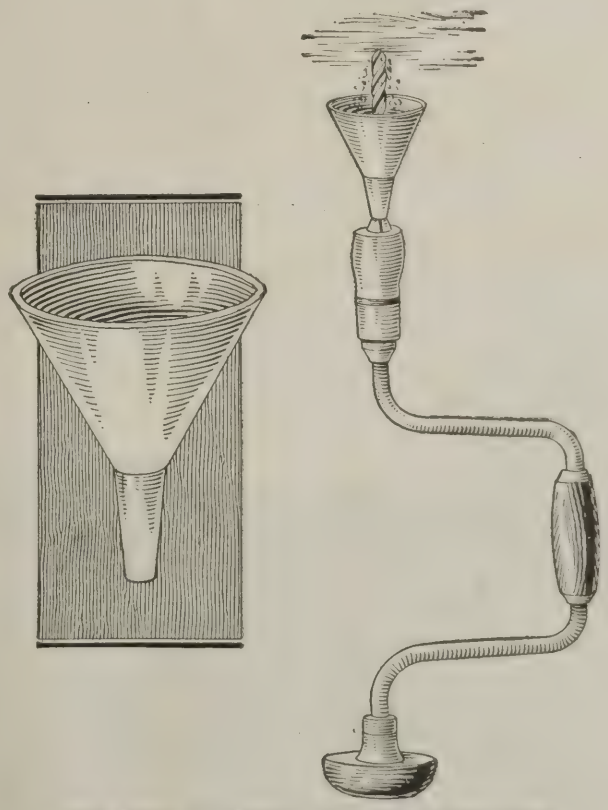
A low-speed machine with an undercut commutator does not operate with the same degree of safety and satisfaction as a high-speed machine. The machine that operates at a sufficiently high peripheral speed to throw off by centrifugal force any particles of dust or other matter which may enter the slots requires much less attention than the low-speed machine.

The principal reason for slotting a commutator is to relieve it of high micas that have not worn down the same amount as the copper bars. The grade of material that is used in the insulation between the commutator segments is not always uniform. Some of the micas will wear down as fast as the copper bars, but it is a more frequent occurrence to have the copper bars wear down faster than the micas. The result is that the mica insulation between the segments is a trifle higher than the copper segments, and this results in a poor contact between the carbon brushes and the commutator bars. This is in turn intensified by the commutator rotating at a high speed. The high micas tend to impart a vibratory motion to the carbon brushes, thus lessening the contact between them and the commutator. The result is that sparking takes place more or less violently, depending upon the condition of the commutator and the micas.

Too often a case of this kind is aggravated instead of relieved by increasing the tension on the carbon brushes, thus causing a still greater wear on the copper bars and brushes. This also causes increased heating of the commutator. There is only one remedy that will cure this trouble and give permanent satisfaction, and that is to undercut the mica.

With a slotted commutator it is possible to use a soft brush; in fact a softer brush should be used with the undercut commutator than is employed with the commutator that is not undercut.

A slotted commutator permits the use of low-friction, non-abrasive brushes, which increases the life of both commutator and brushes, lowers the heating to a minimum and increases the efficiency of the machine.



A commutator that has a raw appearance and will not assume the glossy surface it should have normally can be restored to normal and satisfactory condition at once by undercutting the commutator. It will be found that almost any machine, be it motor or generator, will be improved and a higher efficiency will result from having the commutator undercut.

There are several ways and methods of slotting or undercutting the commutator of an armature. A number of devices are on the market that are made to accomplish this result. Some are made to operate while the armature is in a lathe, or other device, and others are used to undercut with the armature in the machine. One means that is in daily use around small plants and shops is a 4- or 6-in. knife-edge file. After a little practice the operator is able to make fairly good progress in undercutting the micas in the commutator with such an instrument. The micas in all cases should be cut out the full width and length of the commutator bar, and the resulting slot carefully cleaned of all burrs and rough edges. It is not necessary that the slotting be very deep, from $\frac{1}{32}$ to $\frac{1}{16}$ in. being generally sufficient.

Grit Guard for Overhead Drillings

By A. Lucas
Chester Park, N. Y.

To protect the eyes of the man drilling and keep the machinery below free from grit when working overhead, I hit upon the guard shown in the accompanying illustration. It is simple and inexpensive. A

THE CHIP CATCHER AND ITS OPERATION

funnel of suitable size is placed over the drill, and all the grit and chips collected in it. After the work is done, this material can be easily removed and the funnel cleaned out.

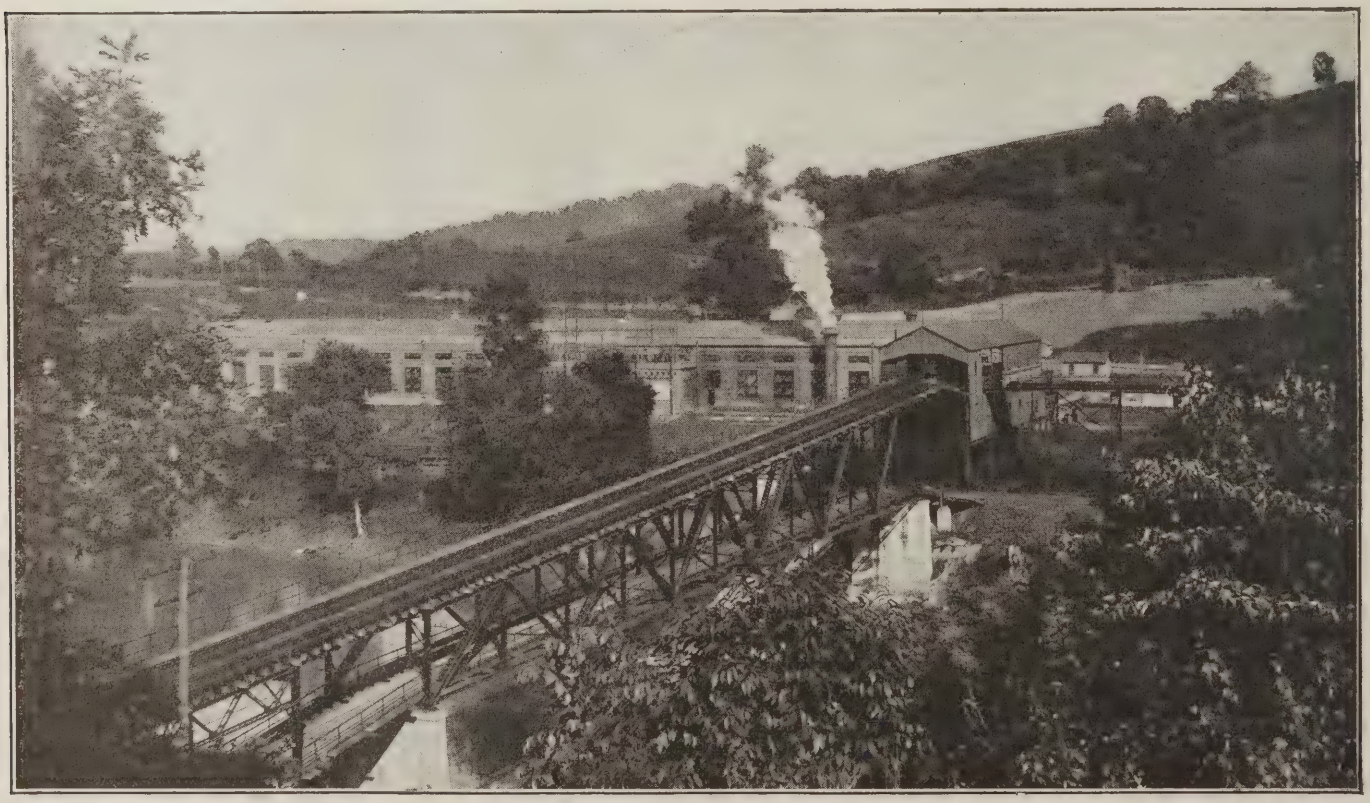
An Electrically Interlocked Car Haul and Car Feeder

By R. P. HINES
Fairmont, W. Va.

SYNOPSIS—*A car feeder within the mine and a car haul leading to the tipple are so connected electrically that the feeder can not be started until the haul is running at normal speed. Both pieces of apparatus may be stopped from various points, and when so stopped cannot be restarted unless the proper switches are reset.*

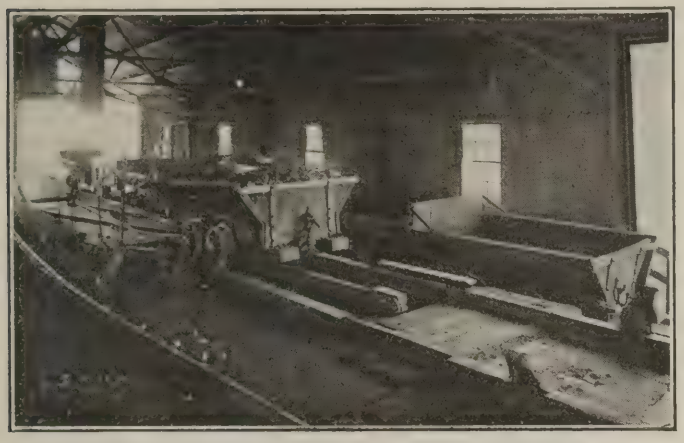


THE two pieces of apparatus which, together with their control, are described in this article are separate and distinct mechanisms. Together, they are used for delivering the loaded coal cars from the bottom of the slope to the dump on the tipple and for returning the empty cars from the tipple to the bottom.

Electric haulage locomotives operating on a 275-volt, direct-current trolley are used to deliver the loaded cars to the bottom and to distribute the empties from this same location. The loaded cars are fed by the car feeder onto the loaded side of the car haul. This pulls them up the slope to the tipple dump and after discharge returns the empties into the mine.

The motor and its starting device for the car feeder are located inside of the mine, approximately 769 ft. from the motor and starting device for the car haul, which are outside, on the tipple. The starters are of the manually operated type and consist of practically standard oil-immersed starting compensators, as it was not deemed advisable in this installation to use the automatic type of starting equipment.

The objects to be attained by the electrical interlock between the two motors and their starting devices were: To render it impossible to start the car feeder, unless the car haul is running and up to speed. To be able to run the car haul without the car feeder being necessarily in operation. To be able to shut down both the car haul and car feeder from any one of several stations; and in the event of the equipment having thus been stopped from any station to make it impossible to again start either or both of the machines, until the switch at the station from which the machinery was stopped has been again placed in its normal operating position. To give an indication to the operator at the car feeder so that in case of a shutdown he can easily determine if it is due to the car feeder; and if so, to make it unlikely that he will attempt to start up until the trouble has been cleared away. In case of a shutdown of the system, due to car-feeder trouble, to make it impossible to start the car haul until the relays on the car-feeder starter are normally reset.



The car haul is of the continuous wire-rope type, dogs being attached to the rope at desired spacing. Guides are provided in which the rollers of the carriages, supporting the rope, run. This rope runs around a master

BRIDGE CARRYING CAR HAUL WITH TIPPLE IN BACKGROUND

wheel on the tipple and a tail pulley at the bottom of the haul, inside the mine. The master wheel on the tipple is driven by a motor through suitable gears and belt connections. The master wheel operates at 2.75 r.p.m. The dogs on the rope, by means of which the cars are attached, are spaced approximately 31 ft. apart. Thus the haul delivers, when operating with each dog carrying a car, 2.75 cars per minute. The cars are provided with a special attachment for engaging the dogs on the rope. The grade up which the haul draws the cars is 25 per cent. for the first 343 ft. at the bottom, and 5.69 per cent. for the balance of 361 ft. to the knuckle, from which the cars run by gravity 65 ft. to the dump.

After a car has been emptied, it is bumped off the dump by the next oncoming car and passes to a kick-back, which delivers it to the empty track of the haul, to be picked up by the rope and returned to the mine. As at present arranged, there are sufficient dogs on the haul to take a maximum of 24 cars on the loaded side and an equal number on the empty side. The descending empty cars aid the motor in pulling up

INTERIOR OF TIPPLE SHOWING CAR DUMP

the loads, so that the minimum load on the motor is with all possible cars on the empty side and no loads coming up. The maximum load is of course with all possible cars coming up on the loaded side and none being returned to the mine on the empty side.

The car-haul motor is a 75-hp., 2200-volt, three-phase, 60-cycle, 900-r.p.m. (synchronous speed), squirrel-cage induction motor, of the regular open type of construction. This motor is connected to the main gears by a Lenix belt drive.

The car feeder inside of the mine operates in much the same manner as the car haul and is designed to handle four cars per minute on a level track onto the car haul. It is gear-driven by a 10-hp., 220-volt, three-phase, 60-cycle, 720-r.p.m. (synchronous speed), squirrel-cage-type open induction motor.

For the control, starting and electrical interlocking arrangement, besides the manually operated motor-starting compensators, there are used two three-pole, oil-immersed, 2200-volt, electrically actuated contactors, two 600-watt, 2200/110-volt potential transformers and two control switches.

The equipment is wired as shown in the accompanying diagram. One of the contactors, called for convenience "the main-line contactor," is connected in the main circuit to the car-haul motor starting com-

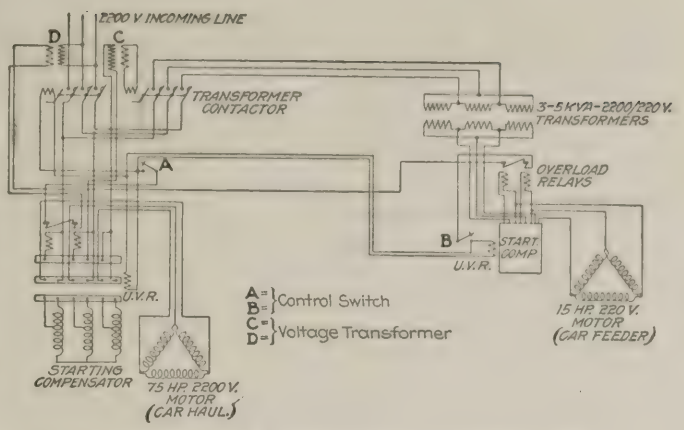


DIAGRAM OF ELECTRICAL CONNECTIONS

pensator. The high-voltage winding of one of the potential transformers is energized from a circuit taken off ahead of the main-line contactor, and from the secondary winding the actuating coil of the main-line contactor and the low-voltage release coils of both starting compensators are energized, there being connected in this control circuit the control switches, like *A* and *B*, for shutting down the system.

The second or transformer contactor has its main contacts connected in the supply circuit to the step-down transformers for the car-feeder motor, located at the pit mouth of the mine, and the actuating coil of this contactor is energized from the low-tension side of a potential transformer whose high-tension winding is connected to the car-haul motor starting compensator so that it is energized only when the starting compensator is thrown to the full running position. This closes the transformer contactor and delivers 2200 volts to the pole-type, step-down transformers for the car-feeder motor, and consequently the proper voltage to the starting compensator for this motor. As is the usual practice the low-voltage release coils of the compensators are wired in series with the contacts of the overload relays on the compensators, which in the compensator for the car-haul motor are self-resetting after opening under overload; but in the compensator for the car-feeder motor these remain open after having been opened by an overload, and have to be manually reset.

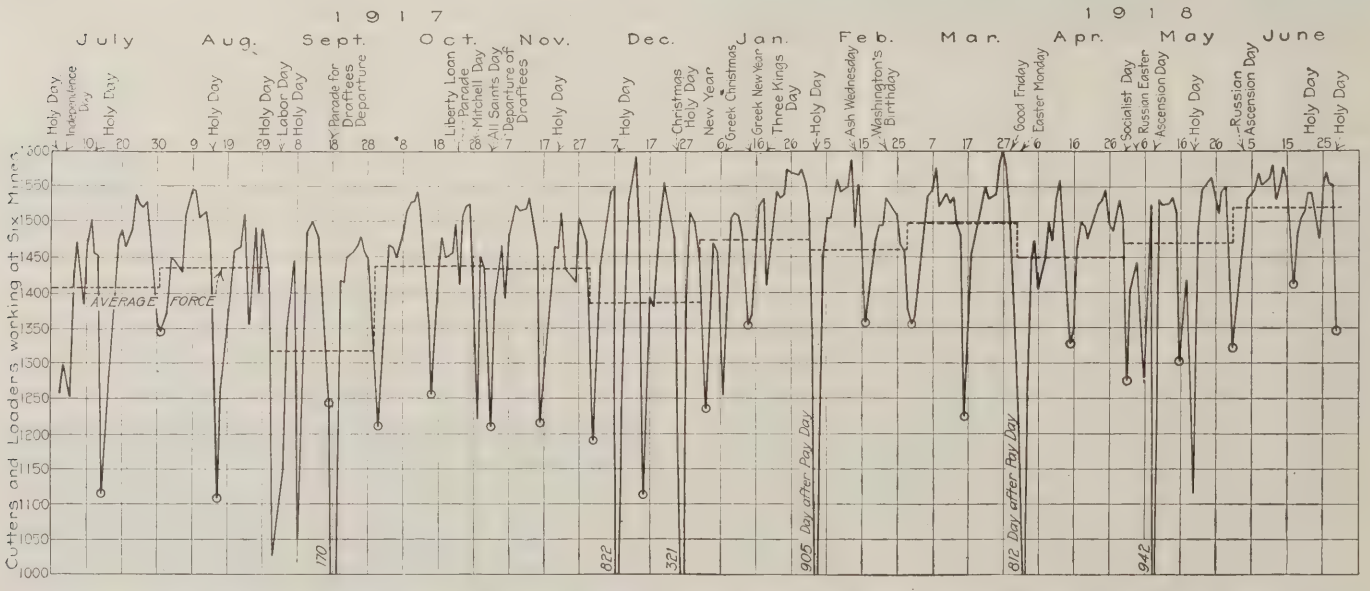
Referring to the diagram of connections, the operation of the system is as follows: With the control switches *A*, *B* and *C* closed, the "main-line contactor" will be closed, which will make circuit to the car-haul

VIEW LOOKING ALONG CAR HAUL

motor starting compensator. The car-haul motor is started by means of this compensator, and when this is thrown to the running position the potential transformer *C* will be energized; the secondary of this transformer being connected across the actuating coil of the three-pole "transformer contactor" will instantly close this contactor, supplying 2200 volts to the high-voltage side of the three 15-kw., 2200/220-volt transformers, and thereby a proper low-voltage supply to the 10-hp. car-feeder motor, which can then be started.

As the low-voltage releases of the two starting compensators and the actuating coil of the "main-line contactor" are all energized from the secondary of the potential transformer *D*, it will readily be seen that if any of the control switches such as *A* or *B* are opened, the whole equipment will be shut down. The transformer contactor will also open, as the primary of the potential transformer *C* will be opened when the 75-hp. starting compensator returns to the "off" position.

If one of the control switches such as *A* or *B* is opened, it will be impossible to start this equipment again until the open control switch is reclosed. If any overload relay on either starting compensator opens, the whole equipment will be shut down. This equipment has been in operation for about four years and has proved quite satisfactory in actual service.



The squirrel-cage type of motor was decided upon because of its ruggedness and serviceability, freedom from moving contacts and ability to operate satisfactorily under adverse conditions of dust, etc., and because it requires practically no attention and is almost "fool-proof." As the tipple is within a few hundred feet of the large central generating station, having approximately 10,000-kv.-a. capacity, and a separate 2200-volt line for its service, the characteristics of the large starting current, etc., of the squirrel cage motor have not proved detrimental.

Tests of momentary starting current with 12 cars on the loaded side, and 6 on the empty side, gave 85.2 amp., the normal full-load current of the motor being 19 amp. With 12 cars on loaded and no cars on the empty side, the running current was 15 amperes.

Intemperate Men Cause Tonnage Loss

THE chart on this page shows the variation in the force of men cutting and loading coal at six mines in the anthracite region. Circles call attention to the number of men reporting on the day after payday. Sometimes, however, the chart cannot record the profundities of low output, and the circle has had to be omitted, a note being substituted.

In the months of July, August and December, 1917, forces of men are always found a few days before the colliery pay. Unquestionably the mines are, even now, not working at full force and the days of carousing which follow pay days and days which commemorate great events in Church history are one cause of the inadequate production. Many people everywhere fail to regard the Fourth of July, Decoration Day, Thanksgiving Day, Lincoln's Birthday and Washington's Birthday as days of solemn commemoration of the nation's holy purpose. And similarly there are very many at the mines who look upon the days which their Church has appointed for certain devout exercises as an opportunity for visiting the saloon and spending the whole day or even more in soul-destroying revelry, contrary to the principles which their Church has always advocated and for which the feasts were instituted.

CURVE SHOWING HOW WORKING FORCE AT SIX ANTHRACITE MINES VARIES OWING TO PAYDAYS AND FESTIVALS

there were three days, each of which followed a pay, on which the force dropped to about 1100 men. This was approximately 500 men short of a normal force, namely 1600 men. Allotting 5 tons to each man, which is considered a fair day's work, there was on each of these days a loss of 2500 tons.

It will be noted that following the pay day of Aug. 31, 1917, the force dropped to 1025 men. The largest

The War and British Coal Supplies

BY MARK MEREDITH
Liverpool, England

SYNOPSIS — *The necessities of war have made it necessary to place the entire coal industry under government regulation. In this work use is constantly made of existing organizations of both miners and operators. Much good has been accomplished and many economies effected through intelligent control of the coal from the mine mouth to the consumer's bin or bunker.*

COAL is a highly necessary munition of war, and the British Board of Trade early recognized its value by controlling it to the fullest possible extent. It was not possible until the early months of this year to collate the information regarding the steps taken by the British government to insure the adequate supply of coal for all purposes, but in an issue of the Board of Trade *Journal* some outline has been given of what has been done.

In the earlier stages of the war a special staff (a section of the Railway Department) had to be set apart for dealing with the question of coal supplies and distribution. Thus there was no sudden change, but a gradual increase in the board's supervision and powers during the early years of the war, until that stage was reached where complete control became, by common consent, essential.

CONGESTION WAS FIRST DIFFICULTY

The first difficulty which arose after the outbreak of war was one of distribution, due to the congestion of the railways. Next came a decrease in production, in consequence chiefly of the enlistment of trained coal miners in the army. The number of miners at work decreased between August, 1914, and June, 1916, by 13.7 per cent., and the loss in efficiency was greater than can be expressed in a numerical percentage. For the departure of trained men, especially those who were young and vigorous, was not compensated for by the influx of other workmen into the coal-mining industry. A third difficulty, which directly led to the taking over of the coal mines, was labor unrest in South Wales.

When the Board of Trade was faced with the problem of distribution, arising out of railway congestion, the Railway Department of the board, in conjunction with the companies (which had been brought under government control as soon as the war began), took such steps as were necessary to expedite supplies to meet local shortages, particularly in the London area.

In the winter of 1914-15, however, it became clear that some more general action was necessary, and pressure was put upon the collieries to secure the continuity of supplies to important consumers. Recognizing that adequate supplies for home consumption was a primary necessity, a coal exports committee was appointed by the board president in May, 1915, to restrict exports, on the recommendation of the retail coal prices committee.

The situation at home was eased by these measures, but the restriction of exports had financial and diplomatic disadvantages, so that it had to be applied cautiously. Since part of the shortage was still local and due to defects in distribution, and in particular in order to insure adequate supplies, it was decided in the second winter of the war to set up distribution committees whose function it was to arrange for the most economical system of distribution.

These district coal and coke supplies committees were appointed in the different colliery districts on the nomination of the local coal owners' associations. A central committee, consisting of representatives of the Board of Trade, the Admiralty, the Home Office, the Ministry of Munitions, the Railway Executive Committee, the coal mining industry, and the coal trade, was also appointed to consider such questions of policy as might arise. This was called the Central Coal and Coke Supplies committee.

NO GENERAL SHORTAGE EXISTED

At first, the committees were upon a voluntary basis, but the inevitable interference with contracts gave rise to legal difficulties and rendered necessary the establishment of the system upon a compulsory basis. The coal output of the kingdom had fallen from 140 million tons for the six months, January to June, 1914, to 128 million tons for the six months, January to June, 1916. The great drop in the output was for the second six months of 1914 (to 123.6 million tons), after which there was a slight but steady advance.

Though there was never during the first two years of the war an actual shortage of coal (taking the country as a whole), the problem of dealing with war and other demands could only be solved by making the best use of the available supply. The industrial demands fell away, while those of the admiralty, of the munition works, and of the allies tended to increase. Half of the French coal fields were, unfortunately, in the possession of the enemy. The first step toward compulsion was taken under the Defense of the Realm Regulations, giving to the government departments concerned power to give directions with a view to securing priority for the delivery of coal and coke. This power was delegated to the joint secretaries of the central coal and coke supplies committee.

Another step toward the assumption of a general control was taken when in July, 1915, the Price of Coal (Limitation) Act was passed. This act resulted from the investigations of a committee, appointed by the president of the Board of Trade on Feb. 25, 1915, to inquire into the retail prices of house coal. The Price of Coal (Limitation) Act prescribed that the price of coal at the pit's mouth must not exceed by more than 4s. ($1) per ton (or such other amount as the Board of Trade might order) the price of the same description of coal sold in similar quantities under similar conditions at the corresponding date during the twelve months ended June 30, 1914.

Voluntary arrangements were made with the London

coal merchants for limiting the retail prices of house coal, and it was suggested to local authorities throughout the country that they might make similar voluntary arrangements with the coal merchants in their districts. The measures, enumerated above, were largely of a voluntary character, and though they met with considerable success, it eventually became clear that a comprehensive scheme for the control of the country's coal supplies was demanded in the national interests.

In February, 1915, the Home Office appointed a coal-mining organization committee, consisting of representatives of coal owners and miners, "to inquire into the conditions prevailing in the coal-mining industry with a view to promoting such organization of work and such coöperation between employers and workmen as, having regard to the large numbers of miners who are enlisting for naval and military service, will secure the necessary production of coal during the war." This committee, which is now merged in the coal controller's department, did much useful work and formed the nucleus of the advisory board of coal owners' and miners' representatives which now assists the controller.

In order, further, to provide for coördination between the committees set up by the Board of Trade and Home Office which were dealing with coal problems, Lord Milner acted for some months before September, 1916, as government supervisor of the supply and distribution of coal. He was chairman of a select committee of four members, of which the other three were the chairman of the coal-mining organization committee, the coal export committee, and the central coal and coke supplies committee. The coal exports committee still remains in being.

Mines Might Be Seized

Labor discontent in South Wales brought matters to a head, and on Nov. 29, 1916, a regulation was made under the Defense of the Realm Act giving to the Board of Trade power to take possession of any coal mines where it appeared to it expedient. The owner of any mine taken over under the regulation is bound to "comply with the directions of the Board of Trade as to the management and use of the mine," but the liability of colliery officials under the Coal Mines Acts are not affected.

Within three months from the taking over of the South Wales coal field all the mines in the kingdom came under control, and the coal mines department had been established by the president of the Board of Trade. On Feb. 22, 1917, an order was issued by the board taking possession of all coal mines as from Mar. 1, and Guy Calthrop, the general manager of the London & North Western Ry., was designated controller of coal mines. An advisory board, consisting of representatives of the coal owners and coal miners, was appointed to assist him. The central coal and coke supplies committee ceased to exist, but the local committees were retained in being, and the scope of their activities has been considerably extended.

The powers given to the coal controller's department are quite comprehensive. The Board of Trade was given authority to take possession of any coal mines and of land for colliery transport purposes, and to exercise powers similar to those of the food controller's with respect to any necessary article of commerce (other than food), and including horses and horse-drawn vehicles. The powers comprise, for example, the regulation of the "production, manufacture, treatment, use, consumption, storage, distribution, supply," etc., of any article, the fixing of maximum or minimum prices, the issue of orders requiring returns as to stocks, authority to requisition stocks, and so on. These wide powers may be exercised either generally or in specific cases. The controller of coal mines has therefore full power to control the production, distribution, prices and consumption of coal, in so far as he may consider necessary.

An agreement between the controller and the mining association, with respect to the compensation to be paid to coal owners in full satisfaction of all claims arising out of control, was signed on July 20, 1917. Under this agreement the owners surrender 95 per cent. of any profits in excess of the "profits standard" (that is, the average profits of the best two out of the three years before the war, or the best four out of six), the controller receiving what is not payable for excess profits duty. The controller, on the other hand, guarantees the pre-war profits standard subject to a reduction where the output is reduced. There is also a limitation of retainable excess profits to one-fifth of the profits standard.

Where the controller closes a mine, the cost of maintaining and reinstating it does not fall on the state, but may (on the application of district associations) be met by a levy on the districts in which it is situated. Provisions are included for fixing substitutes for the profits standard in case of hardship. This agreement received royal assent as the Coal Mines Control Agreement (Confirmation) Act.

The objects that the controller set himself to accomplish were as follows: To control the whole production and distribution of coal in the national interest and to remove the chief cause of labor unrest by making it possible for the men to feel that they were working for the community, and not in order to earn excessive profits for the coal owners.

Existing Organizations Utilized

From the first it has been the controller's desire to make the fullest use of the existing machinery of the coal-owners' and of the miners' organizations. With this object in view, an advisory board was set up with which he would be kept in constant touch, and by whose experience and technical knowledge he could be assisted. The board consists of seven representatives of coal owners and seven officials of the miners' federation.

This advisory board meets about twice each month and has considered such important questions as recruiting, labor disputes, miners' holidays, mobility (the transfer of men from one district to another), short time and absenteeism, the settlement of price lists, and the supply of pitwood. The assistance of the advisory board has been of the greatest value, and has enabled the controller rapidly to explore the problems which constantly arise upon his horizon.

One of the chief objects of control was to maintain the output of coal, and the postponement of development work was recommended by the coal-mining organization committee in its first report as one means of keeping production at the maximum. It is an essential feature

of the system of control that the actual management of the mines should remain as far as possible in the hands of the owners, but considerations of man-power and the shortage of materials render some regulation unavoidable. Both material and labor must be put to the most productive use, and be kept for those classes of coal which were most in demand. New sinkings are rarely permitted. The employment of a staff of district inspectors has been sanctioned by the treasury, and these officers report on the necessity of proposed works, and on the relative urgency of demands for materials.

Experience since the coal mines were taken over justifies the assertion that the miners now realize that they are working for their country, rather than for the private profit of their employers. There has been a marked decrease in industrial unrest, and a greater willingness to regard work in the mines as war-service of the first importance. The chief labor event since the control was established was the demand of the miners' federations for a 25 per cent. increase in wages to meet the increased cost of living.

This demand was presented on Aug. 28, 1917. As the result of subsequent negotiations the miners finally accepted increases of 9s. ($2.25), and 4s.6d. ($1.12) in the case of boys, a week—that is, 1s.6d. (37c.) a day for each day on which a man works or is ready and able to work, and 9d. (18c.) a day for boys under 16 years old. A feature of the arrangement is that the increase of 1s.6d. (or 9d.) a day is paid even when the pit is idle for lack of orders; for example, in the exporting districts—and this is done in order to give some relief to men in the export districts who are suffering from irregular working of the mines, as the result of shipping losses. Such irregularity is no fault of theirs or of the coal owners.

By the foregoing arrangement with the miners, the controller was able to convert a demand for a percentage increase into the concession of a flat rate. An advance on a percentage basis would have chiefly benefited men who were getting regular work, and who were previously earning the highest wages. The settlement has been extended by the Ministry of Munitions to workers in many cognate industries. The "war wage," as it is called, dates back to Sept. 17, 1917. An inevitable consequence has been an increase in the pithead prices of coal of 2s.6d. (62c.) a ton.

Disputes Are Reported

While the policy of the department is to insist upon the use of local machinery of owners' and miners' associations for the settlement of disputes, a close watch at headquarters is kept upon them. All disputes which may involve a stoppage of work are reported at once to the controller. His friendly offices are always at the disposal of the parties, either personally in London, or locally through members of his staff.

The controller of coal mines inherited from the Home Office the functions of that department regarding the recruitment of miners, with the exception of the supervision of the colliery recruiting courts. The central court sits at the coal mines department and one of the staff acts as its secretary. These functions have now been transferred by the war cabinet to the Ministry of National Service, while the controller continues to act in an advisory capacity.

One of the most difficult problems before the controller has arisen from the diminished supply of ships in certain export districts (East Fifeshire, the Lothians, Northumberland, Durham and portions of the South Wales field). It is not possible to keep the pits in these districts regularly working and the men constantly employed, although in most other coalfields, and in many other industries of national importance, there is an acute shortage of labor.

The problem has been to make labor more mobile and to effect the necessary transference. Various measures are being taken to solve the difficulties which have arisen. For example, by arrangement with the railway executive committee, a train service was put on to enable miners who live in the east of Fifeshire (where short-time operations have been serious) to go to the western districts of that county where the pits are working better. Special commissions of inquiry (of which the local miners' leaders are members) investigate the short time worked in some districts, and make suggestions for an improvement.

Mobility Bureaus Are Established

In order to deal with the whole question systematically the controller placed before the miners' federation of Great Britain a proposal for the establishment of mobility bureaus, to be managed by the miners' federation and their district associations. The purpose of the bureau was to transfer coal miners from operations that were not working full time, to other coal, fireclay or ganister mines where their labor was required. The federation has accepted the proposal and district mobility bureaus are being set up. The controller is also collaborating with other departments (such as the Ministries of Munitions and of National Service) in order to transfer surplus mining labor into other occupations, such as timber-felling, iron-stone and iron-ore mining, the shipyards, etc.

The broad results of the measures which have been taken by the Board of Trade may be shown by the figures of coal outputs since the war began. They are given below in millions of tons for six-month periods during the four years 1914, 1915, 1916 and 1917:

	Million Tons		Million Tons
January to June, 1914.....	140.0	January to June, 1916.....	128.3
July to December, 1914....	125.6	July to December, 1916....	128.1
January to June, 1915.....	127.6	January to June, 1917.....	126.4
July to December, 1915....	126.6	July to December, 1917....	121.3

It is remarkable when all the difficulties are considered that have arisen through the long duration of the war and the calls upon the national man-power, that the output of the British coal mines during the last year amounted to 247.7 million tons, or only 8.7 million tons (3.4 per cent.) less than during 1916. It was not until the second half of 1917 that the output fell below that for the second half of 1914.

It will be seen from the foregoing figures of output that there has never been a shortage of coal in the sense that there has been a shortage of petrol (gasoline). All the coal used in Great Britain is there produced; while, with the exception of the comparatively small production from Scottish shale, we import all our petrol supplies.

The coal problem has, throughout, been primarily one of labor and distribution. The government control of the collieries, through the Department of Coal Mines,

has facilitated the apportionment of supplies of fuel to industrial consumers of national importance, particularly in those cases in which it has been necessary to provide supplies of special qualities or grades of coal by diversion from consumers of less importance.

To effect economies in railway transport, a redistribution scheme was worked out with the object of maintaining the consumption of coal as near as possible to the point of production. The necessary powers were provided by the coal-transport order of 1917 (made by the Board of Trade under the Defense of the Realm Regulations on July 4, 1917) and by the direction of the controller of coal mines which were issued under this order. The country was divided into areas, the interchange of coal between producing areas was restricted, and consuming districts were allotted specific sources of supply.

The redistribution scheme came into operation on Sept. 19, and the estimated saving in railway haulage alone—apart from other economies in railway operation—is 700 million ton-miles annually. The controller is now taking up the question of unnecessary transport within the areas. Canal transport for coal is made use of wherever practicable. The department has been able to accumulate technical records of all industrial processes, and its staff is assisted by representatives throughout the country. Firms are visited and reports submitted upon any difficulty which arises out of the allocation of supplies.

The Regulation of Household Consumption

When it was decided in August, 1917, to control household consumption of coal in the London area, steps were taken to register all coal merchants, to set up local organizations for watching the interests of consumers, and to devise a scale of allowances which would be equitable as between the different classes of users. All persons engaged in the distribution of coal were recorded and arrangements made to keep each one under review, so as to insure that he continued effectively to carry on his trade.

A census of men and horses was undertaken in order to protect the facilities for distribution and, if possible, to augment them. The coöperation of the food production department of the Board of Agriculture was secured in regard to horses. A local organization for watching the interests of consumers was set up by the appointment of local coal overseers by the local authorities in each district. With a view to assisting the local coal overseers, a coal merchant, known as the coal merchants' supervisor, was appointed in each district as well. This organization, which involves the coöperation of representatives of both merchants and consumers, enables local troubles to be settled at the source.

In order that an equitable distribution of coal might be secured, allowances were fixed in respect to houses of different sizes, and arrangements made to assess exceptional buildings and premises. Forms for requisition were issued for the purpose early in September, and the machinery has worked smoothly and satisfactorily.

The object of the scheme of allowance was to reduce the extravagant consumption of coal by the wealthy classes, to do away with the use of coal in unnecessary buildings, and thus to insure that a supply should be available for the poorer people. At the same time it was sought to diminish the total demand for coal. A reduction in the amount burned was made urgent by the difficulties of labor and transport.

A special section of this branch of the control system has been set up to review the facilities for selling coal in small quantities. Stocks were provided in difficult areas under the control of the local authorities, and every encouragement was given to the small dealers and retailers to continue in business. The demands of the war have encroached severely upon this unorganized body of distributors, many of whom carried on one-man businesses. It was by no means easy to organize those who still remained and to supplement their effectiveness from other sources.

Local house-coal distribution committees have been appointed in towns with a population of 20,000 or over, and emergency stocks of coal are being accumulated in these municipalities under the direct control of the local authorities. Smaller towns have been invited to combine their urban and rural districts to form committees on similar lines; and, as in the case of the larger towns, the controller's representatives visit the committees in an advisory capacity.

The prices of coal at the pit's mouth were fixed by the Price of Coal (Limitation) Act, passed in July, 1915. Under the régime of the controller of coal mines the regulation of prices was extended to cover both wholesale merchants' charges and retail prices. Powers were conferred by the wholesale-coal-prices order and the retail-coal-prices order made by the Board of Trade on Sept. 5 and 11 respectively. The function of fixing in each locality the maximum retail prices of house coal which would comply with the requirements of the retail-coal-prices order was assigned to local authorities throughout the United Kingdom.

Exports Decreased

The effect of the shortage of shipping resulting from the operations of enemy submarines was felt in the early part of 1917 in the form of a considerable reduction in the quantity of coal exported, and a serious decline in export prices. In order to deal with the proposition of prices, a code of directions as to the sale of coal was issued by the controller of coal mines on June 28, 1917, embodying a schedule of prices for coal sold for export or bunkering. The scheduled prices operate as fixed prices in the case of shipments to France and Italy.

The much-reduced imports of pitwood made difficult the provision of adequate supplies of props, without which coal mining could not go on. At first the controller made use of the personnel of the old pit timber committees throughout the country which had been set up by the Home Office, and which were worked under a joint committee of members of the coal-mining organization committee of the Board of Agriculture with a representative of the Board of Trade. He also appointed eight district pitwood committees throughout the country, the chairman in each case being one of H. M. inspectors of mines, with an officer paid by the controller to act as the chairman and technical assistant.

The first duty of these committees was to perfect

the formation of district pitwood associations, and seven associations have been formed to develop the supply of home-grown timber, which became necessary as the result of the curtailment of the importation of pitwood by the war cabinet. The great majority of the collieries are readily joining these pitwood associations, and colliery owners who show reluctance are being strongly pressed to join.

In July the controller of timber supplies offered to take over from the controller of coal mines the duty of supplying the collieries with pitwood and other necessary timber together with the supervision of the district pitwood committees. This offer was accepted, and the controller of timber supplies is now responsible for the work. The functions of the controller of coal mines respecting pitwood have been confined, since then, mainly to watching the activities of the district pitwood committees, encouraging the formation of pitwood associations, and dealing with applications from colliery companies for permits to purchase soft imported wood.

On Dec. 19 the controller of coal mines (acting after consultation with the controller of timber supplies) issued detailed instructions regarding stocks, prices and contracts for pitwood and other mining timber. Stocks were limited to twelve months' future consumption. This was done because some collieries had stocks much exceeding their requirements for such a period, while others had nothing like that quantity. The maximum prices which collieries were permitted to pay were fixed in accordance with the various classes of timber and the position of the coal fields. Certain existing contracts for pitwood were ordered to be submitted to the controller for direction and advice as to revision.

Results Obtained Justify Control
